U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus and Divisions.

WEATHER BUREAU—Willis L. Moore, *Chief*.
BUREAU OF ANIMAL INDUSTRY—D. E. Salmon, *Chief*.
BUREAU OF PLANT INDUSTRY—B. T. Galloway, *Chief*.
BUREAU OF FORESTRY—Gifford Pinchot, *Forester*.
BUREAU OF SOILS—M. Whitney, *Chief*.
BUREAU OF CHEMISTRY—H. W. Wiley, *Chemist*.
DIVISION OF STATISTICS—J. Hyde, *Statistician*.
DIVISION OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
DIVISION OF BIOLOGICAL SURVEY—C. Hart Merriam, *Chief*.
SECTION OF FOREIGN MARKETS—F. H. Hitchcock, *Chief*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA—

College Station: *Auburn*; P. H. Mell.*
Canebrake Station: *Uniontown*; H. Benton.*
Tuskegee Station: *Tuskegee*; G. W. Carver.*

ALASKA—*Sitka*; C. C. Gorges.[†]

ARIZONA—*Tucson*; R. H. Forbes.*

ARKANSAS—*Fayetteville*; R. L. Bennett.*

CALIFORNIA—*Berkeley*; E. W. Hilgard.*

COLORADO—*Fort Collins*; L. G. Carpenter.*

CONNECTICUT—

State Station: *New Haven*; E. H. Jenkins.*

Storrs Station: *Storrs*; W. O. Atwater.*

DELAWARE—*Newark*; A. T. Neale.*

FLORIDA—*Lake City*; T. H. Taliaferro.*

GEORGIA—*Experiment*; R. J. Redding.*

HAWAII—

Federal Station: *Honolulu*; J. G. Smith.[‡]

Sugar Planters' Station: *Honolulu*; R. E. Blouin.*

IDAHO—*Moscow*; J. A. McLean.*

ILLINOIS—*Urbana*; E. Davenport.*

INDIANA—*Lafayette*; C. S. Plumb.*

IOWA—*Iowa*; C. F. Curtiss.*

KANSAS—*Manhattan*; J. T. Willard.*

KENTUCKY—*Lexington*; M. A. Scovell.*

LOUISIANA—

State Station: *Baton Rouge*;

Sugar Station: *Audubon Park, New Orleans*;

North Louisiana Station: *Calhoun*; W. C. Stubbs.*

MAINE—*Orono*; C. D. Woods.*

MARYLAND—*College Park*; H. J. Patterson.*

MASSACHUSETTS—*Amherst*; H. H. Goodell.*

MICHIGAN—*Agricultural College*; C. D. Smith.*

MINNESOTA—*St. Anthony Park, St. Paul*; W. M. Liggett.*

MISSISSIPPI—*Agricultural College*; W. L. Hutchinson.*

MISSOURI—

College Station: *Columbia*; H. J. Waters.*

Fruit Station: *Mountain Grove*; J. T. Stinson.*

MONTANA—*Bozeman*; S. Fortier.*

NEBRASKA—*Lincoln*; E. A. Burnett.*

NEVADA—*Reno*; J. E. Stubbs.*

NEW HAMPSHIRE—*Durham*; C. S. Murkland.*

NEW JERSEY—*New Brunswick*; E. B. Voorhees.*

NEW MEXICO—*Mesilla Park*; J. D. Tinsley.[‡]

NEW YORK—

State Station: *Geneva*; W. H. Jordan.*

Cornell Station: *Ithaca*; I. P. Roberts.*

NORTH CAROLINA—*Raleigh*; B. W. Kilgore.*

NORTH DAKOTA—*Agricultural College*; J. H.

Worst.*

OHIO—*Wooster*; C. E. Thorne.*

OKLAHOMA—*Stillwater*; J. Fields.*

OREGON—*Corvallis*; T. M. Gateh.*

PENNSYLVANIA—*State College*; H. P. Armsby.*

PORTO RICO—*San Juan*; F. D. Gardner.[‡]

RHODE ISLAND—*Kingston*; H. J. Wheeler.*

SOUTH CAROLINA—*Clemson College*; H. S. Hartz.*

SOUTH DAKOTA—*Brookings*; John W. Heston.[§]

TENNESSEE—*Knoxville*; A. M. Soule.[‡]

TEXAS—*College Station*; J. H. Connell.*

UTAH—*Logan*; J. A. Widtsoe.*

VERMONT—*Burlington*; J. L. Hills.*

VIRGINIA—*Blacksburg*; J. M. McBryde.*

WASHINGTON—*Pullman*; E. A. Bryan.*

WEST VIRGINIA—*Morgantown*; J. H. Stewart.*

WISCONSIN—*Madison*; W. A. Henry.*

WYOMING—*Laramie*; E. E. Smiley.*

* Director.

† Special agent in charge.

‡ Vice-director.

§ Acting director.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The EDITOR and H. W. LAWSON.
 Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural
 Engineering—W. H. BEAL.
 Botany and Diseases of Plants—WALTER H. EVANS, PH. D.
 Foods and Animal Production—C. F. LANGWORTHY, PH. D.
 Field Crops—J. I. SCHULTE.
 Entomology and Veterinary Science—E. V. WILCOX, PH. D.
 Horticulture—C. B. SMITH.
 With the cooperation of the scientific divisions of the Department and the Abstract
 Committee of the Association of Official Agricultural Chemists.

EDITORIAL NOTES.

	Page
The promotion of agriculture in Russia	1
Agricultural experiment stations for Hawaii and Porto Rico.....	2
International congresses of agricultural experiment stations and of agricul- tural education at Paris.....	101
The late Sir John Bennet Lawes	201
The influence of the Rothamsted Experiment Station.....	203
Experiment stations' exhibits at the Paris Exposition.....	301
Need of more perfect organization of the experiment stations.....	401
Differentiation of the investigator from the teacher	403
Some recent bibliographic helps.....	501
Protection of crops from hail.....	502
The scope and management of the veterinary work of the experiment stations.....	601
Investigation of soils in Russia	701
Variety testing at Woburn Experimental Fruit Farm	703
Cheese curing in the light of the enzym theory.....	801
The agricultural appropriation act	803
Experiment-station farms, and the movement for their establishment in Ger- many	901
The Hawaii Experiment Station.....	1001
Maxime Cornu, botanist, horticulturist, and agriculturist	1002

SPECIAL ARTICLES.

Notes on horse feeding, E. Lavalard	4
New agricultural building at Kansas State Agricultural College	103
International congresses of horticulture, viticulture, and agriculture at Paris, W. H. Evans, Ph. D	205
Fourteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations, E. W. Allen	404

	Page.
Convention of Association of Official Agricultural Chemists, 1900, D. W. May.	503
New building for the College of Agriculture at the University of Illinois	604
Russian soil investigations	704, 807

LIST OF STATION PUBLICATIONS ABSTRACTED.

ALABAMA COLLEGE STATION:

Bulletin 107, December, 1899	433
108, April, 1900	551, 569
109, July, 1900	854
Index to Vol. VII, Bulletins 101-107 and Twelfth Annual Report, January-December, 1899	498
Twelfth Annual Report, 1899	97

ALABAMA TUSKEGEE STATION:

Bulletin 3, November, 1899	331
----------------------------	-----

ARIZONA STATION:

Bulletin 31, December, 1899	334
32, December, 1899	364
33, April 13, 1900	458
34, June 30, 1900	798
35, August 15, 1900	753
Eleventh Annual Report, 1900..	1019, 1031, 1038, 1042, 1043, 1049, 1055, 1074, 1097

ARKANSAS STATION:

Bulletin 59, December, 1899	136
60, December, 1899	151
61, July, 1900	634
62, November, 1900	1034
63, December, 1900	1084
Twelfth Annual Report, 1899	296

CALIFORNIA STATION:

Bulletin 126, 1899	64
127, 1900	241
128, March, 1900	221
129, May, 1900	643
130, August, 1900	794
Circular, September, 1898	350
Exchange Seed List No. 5, December, 1900	1014
Annual Report, 1898	906, 912, 914, 921, 923, 926, 936, 942, 943, 945, 946, 954, 961, 965, 975, 980, 981, 991, 995, 996

COLORADO STATION:

Bulletin 53, March, 1900	246
54, May, 1900	658
Twelfth Annual Report, 1899	220, 222, 229, 244, 248, 261, 265, 275, 294, 296, 297

CONNECTICUT STATE STATION:

Bulletin 130, January, 1900	70
131, November, 1900	957
Twenty-third Annual Report, 1899, Part I	128
Twenty-third Annual Report, 1899, Part II	213, 214, 279, 280, 281, 282
Twenty-third Annual Report, 1899, Part III	512, 513, 514, 527, 528, 542, 544, 547, 549, 557, 558, 563, 565, 567, 568, 570, 571, 580, 581, 599
Annual Report, 1900, Part I	931

CONNECTICUT STORRS STATION:

Bulletin 20, March, 1900	380
21, March, 1900	387
Twelfth Annual Report, 1899	1016, 1025, 1028, 1069, 1071, 1075, 1076, 1077, 1083, 1086, 1097

DELAWARE STATION:

	Page.
Bulletin 46, May, 1900.....	435, 481
47, September, 1900	894
48, October, 1900.....	852
49, December, 1900.....	970
Eleventh Annual Report, 1899	721, 724, 729, 739, 753, 761, 771, 775, 787, 797

FLORIDA STATION:

Bulletin 51, January, 1900	68
52, February, 1900	477
53, March, 1900.....	463
54, August, 1900	751
55, September, 1900	778
Report for 1899 and 1900	1015, 1036, 1045, 1056, 1057, 1097

GEORGIA STATION:

Bulletin 47, December, 1899.....	137
48, January, 1900	148
49, September, 1900	982, 986, 992
50, October, 1900.....	962
Twelfth Annual Report, 1899	50, 61, 62, 97

IDAHO STATION:

Bulletin 21, February, 1900	156
22, 1900	342
23, April, 1900	314, 316, 320
24, May, 1900.....	641, 670
25, January, 1901	1066

ILLINOIS STATION:

Bulletin 57, March, 1900.....	355
58, April, 1900	370
59, April, 1900	345
60, August, 1900	868
Twelfth Annual Report, 1899	97

INDIANA STATION:

Bulletin 80, September, 1899	189
81, December, 1899.....	126
82, March, 1900	876
83, August, 1900	854
84, September, 1900	1040
85, October, 1900.....	1054
86, December, 1900.....	1075
Twelfth Annual Report, 1899.....	21,
	22, 41, 44, 45, 47, 53, 54, 57, 70, 78, 80, 94, 95, 96, 97

IOWA STATION:

Bulletin 44, February, 1900	147
45, February, 1900	134
46, March, 1900	240
47, March, 1900	340
48, June, 1900	671, 673
49, June, 1900	664
50, June, 1900	665
51, August, 1900	639
52, September, 1900	881, 882, 883
53, November, 1900	962
Biennial Report, 1898-99.....	97

KANSAS STATION:

X EXPERIMENT STATION RECORD.

OHIO STATION—Continued.

Page.

Special Bulletin 4, April 23, 1900	349
Eighteenth Annual Report, 1899	198
Nineteenth Annual Report, 1900	975, 997

OKLAHOMA STATION:

Bulletin 44, December, 1899	230
45, March, 1900	312
46, May, 1900	872
47, September, 1900	846, 850
Annual Report, 1900 ... 622, 623, 640, 648, 652, 657, 664, 670, 677, 691, 692, 693, 697	

OREGON STATION:

Bulletin 60, January, 1900	58
61, March, 1900	343
62, June, 1900	419, 443, 445, 471, 476
63, November, 1900	1052
64, December, 1900	1092
Annual Report, 1896	997
1898	906, 997
1899	907, 997
1900	942, 997

PENNSYLVANIA STATION:

Bulletin 47, November, 1899	44
48, December, 1899	71
49, February, 1900	339
50, February, 1900	378
51, April, 1900	645
52, June, 1900	678
53, September, 1900	875
54, November, 1900	927
Annual Report, 1899	618, 632, 649, 651, 669, 678, 697

RHODE ISLAND STATION:

Bulletin 60, November, 1899	39
61, December, 1899	192
62, February, 1900	222
63, February, 1900	282
64, March, 1900	378
65, April, 1900	333
66, April, 1900	634
67, May, 1900	626
68, June, 1900	621
69, June, 1900	735
70, July, 1900	737
71, August, 1900	935
72, September, 1900	982
73, October, 1900	933
74, November, 1900	1030
75, December, 1900	1030
Twelfth Annual Report, 1899	717,
	724, 727, 732, 735, 737, 740, 746, 760, 763, 781, 798
Thirteenth Annual Report, 1900	907, 919, 927, 944, 952, 966, 974, 982, 990, 997

SOUTH CAROLINA STATION:

Bulletin 48, December, 1899	196
49, January, 1900	151
50, January, 1900	291

SOUTH CAROLINA STATION—Continued.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.¹
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH and V. A. CLARK.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. I.

Editorial notes:	Page.
The promotion of agriculture in Russia	1
Agricultural experiment stations for Hawaii and Porto Rico.....	2
Notes on horse feeding, E. Lavalard	4
Recent work in agricultural science.....	18
Notes.....	99

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

The volumetric determination of potash, R. H. Adie and T. B. Wood.....	18
A new reagent for detecting and estimating nitrites in water, H. Erdmann...	18
Methods for the detection of "process" or "renovated" butter, W. H. Hess and R. E. Doolittle.....	18
A comparison of reagents for milk proteids with some notes on the Kjeldahl method for nitrogen determination, A. Vivian.....	19
Tests for the strength of solutions of formaldehyde, H. A. Huston.....	21
Reducing power of taka-diastrase, H. A. Huston and A. H. Bryan.....	22

BOTANY.

American grasses—III, F. Lamson-Scribner	24
Notes on useful plants of Mexico, J. N. Rose	24
Studies of Mexican and Central American plants—No. 2, J. N. Rose.....	24

¹ Absent on leave.

	Page.
Two new species of plants from the Northwestern United States, L. F. Henderson .	24
Hesperogenia, a new genus of Umbelliferae from Mount Rainier, J. M. Coulter and J. N. Rose	24
Three new species of Tradescantia in the United States, J. N. Rose	24
Treleasea, a new genus of Commelinaceae, J. N. Rose	24
Lists of trees and shrubs on the grounds of Purdue University	24
The origin and early development of the flowers of the cherry, plum, apple, and pear, E. S. Goff	22
Comparative hardness of flower buds in the cherry, E. S. Goff	23
Yellow coloring matters accompanying chlorophyll and their spectroscopic relations, C. A. Schunck	23

METEOROLOGY.

Annual summary of meteorological observations in the United States, 1899 ...	25
The climate of San Francisco, Cal., A. G. McAdie and G. H. Willson	27
The meteorology of Ben Nevis in clear and in foggy weather, J. Y. Buchanan.	27
Meteorological observations, J. E. Ostrander and A. C. Monahan	28
Meteorological record	28

SOILS.

The soluble salts of cultivated soils, F. H. King and J. A. Jeffery	28
The character and treatment of swamp or humus soil, F. H. King and J. A. Jeffery	32
Percolation and evaporation from long columns of soil, F. H. King	34
The utilization by plants of the potash dissolved in soil water, T. Schloesing..	36
Catalogue of the first four thousand samples in the soil collection of the Division of Soils, M. Whitney	36
Treatment of swamp or humus soil, F. H. King and J. A. Jeffery	36
Readings of soil thermometers	36

FERTILIZERS.

The utilization of stable waste, W. H. Birchmore	37
Investigations on the influence of nitric nitrogen and ammoniacal nitrogen on the growth of maize, P. Mazé	37
Analyses of commercial fertilizers, W. F. Hand et al.	38
Analyses of commercial fertilizers, H. J. Wheeler and B. L. Hartwell	39
Report of fertilizer department, J. P. Smith	39
Report of chemist, M. B. Hardin	39
Analyses of licensed commercial fertilizers, 1899, F. W. Woll and A. Vivian..	39

FIELD CROPS.

The influence of the right amount and right distribution of water in crop production, F. H. King	40
Continued effects of fertilizing the soil, W. C. Latta	41
Variety tests of grains, R. A. Moore	42
Machine and hand-threshed cereals for seed, H. C. Schellenberg	42
Russian cereals adapted for cultivation in the United States, M. A. Carleton...	45
The nitrogen fertilization of barley for brewing, T. Remy	42
Report on culture experiments with barley at the Berlin Experimental Institute for Brewers, von Eckenbrecher	43
Forage crops, W. B. Anderson	45
The influence of heredity upon vigor in the potato, E. S. Goff	43

	Page.
The present status of rice culture in the United States, S. A. Knapp	46
Tests of the sugar beet in Pennsylvania, H. P. Armsby and E. H. Hess.....	44
Field tests of varieties of wheat, covering nineteen years, W. C. Latta.....	47
Test of corn-cultural implements, W. C. Latta.....	44

HORTICULTURE.

A study of the effect of incandescent gaslight on plant growth, L. C. Corbett..	47
The use of chemical fertilizers in the forcing house, W. Stuart	48
Experiments in forcing vegetables, J. Troop.....	54
The effect of transplanting on time of maturity, F. Cranefield	49
Report of the horticulturist, A. L. Quaintance	50
Field notes of horticultural department, C. B. Waldron.....	51
Russian apples in Indiana, J. Troop	54
Preliminary report on experiments in pinching raspberry shoots, E. S. Goff...	51
Preserving fruit for exhibition, F. Cranefield.....	53
Rose growing with chemical fertilizers, W. Stuart	53
Some hints on ornamental planting, C. B. Waldron	55

DISEASES OF PLANTS.

Notes on various plant diseases, F. C. Stewart.....	55
Plant diseases, A. L. Quaintance	61
Corn smut, J. C. Arthur and W. Stuart	57
Asparagus rust, P. H. Rolfs.....	61
Club root, W. Hawk	57
Apple-tree anthracnose, A. B. Cordley.....	58
The New York apple-tree canker, W. Paddock	59

ENTOMOLOGY.

How to distinguish the different mosquitoes of North America, L. O. Howard and D. W. Coquillett.....	68
Insect notes for 1899, A. L. Quaintance	62
Apple insects of Maine, F. L. Harvey and W. M. Munson	68
The peach-tree borer, M. V. Slingerland.....	63
Some common Florida scales, H. A. Gossard.....	68
Preliminary report on the insect enemies of forests in the Northwest, A. D. Hopkins.....	64
Paris green for the codling moth, C. W. Woodworth and G. E. Colby	64
Report of analyses of Paris green and other insecticides, L. L. Van Slyke.....	67

FOODS—ANIMAL PRODUCTION.

Nuts as food, C. D. Woods and L. H. Merrill	78
Cereal breakfast foods, C. D. Woods and L. H. Merrill	69
Analyses of maple sugar, H. A. Huston and A. H. Bryan.....	78
Commercial feeding stuffs in the Connecticut market, E. H. Jenkins, A. L. Winton, et al	70
Analyses of feeding stuffs, H. A. Huston and A. H. Bryan	70
Analyses of feeding stuffs, F. W. Woll	71
Winter v. spring bran, W. Frear and W. A. Hutchison.....	71
Contribution to the study of the energy content of human urine, M. Tangl ...	72
Sheep feeding, R. T. Shaw	72
Sheep-feeding experiments, J. H. Stewart and H. Atwood	73

	Page.
Feeding ground corn v. ground peas to lambs before and after weaning, W. L. Carlyle	74
The influence of manures on the production of mutton, W. Somerville	75
Whole corn compared with corn meal for fattening swine, W. A. Henry	75
Rape v. clover for young pigs, W. L. Carlyle	76
On the food requirements of the pig for maintenance and for gain, W. Dietrich, reported by F. W. Woll	77

DAIRY FARMING—DAIRYING.

The mammary gland, A. W. Bitting	80
On the economy of heavy grain feeding of dairy cows, F. W. Woll and W. L. Carlyle	81
Protecting cows from flies, W. L. Carlyle	82
The effect on dairy cows of changing milkers, W. L. Carlyle	83
Dairy herd record, W. L. Carlyle	83
Tests of dairy cows, 1898-99, J. W. Decker	90
The composition of sow's milk, F. W. Woll	84
Examination of milk for tubercle bacilli, V. H. Bassett	90
Pasteurization of milk and cream at 140° F., E. H. Farrington and H. L. Russell	84
Pasteurization of skim milk, E. H. Farrington	85
Effect of salt on the water in butter, E. H. Farrington	86
White spots on butter, E. H. Farrington	87
Coating cheese with paraffin to prevent mold, J. W. Decker	91
The action of proteolytic ferments on milk with special reference to galactase, the cheese-ripening enzym, S. M. Babcock, H. L. Russell, et al.	87
Influence of galactase in the ripening of cottage cheese, S. M. Babcock, H. L. Russell, and A. Vivian	88
Effect of digesting bacteria on cheese solids of milk, H. L. Russell and V. H. Bassett	89
Notes upon dairying in California and the export of California butter to the Orient, R. A. Pearson	89
A composite milk-sampling pipette, J. W. Decker	91
Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1900	92

VETERINARY SCIENCE AND PRACTICE.

Report of the cattle quarantines in Canada from November 1, 1897, to October 31, 1898, D. McEachran	92
Effect of different influences on normal temperatures of cattle, and relation of same to tuberculin test, H. L. Russell and V. H. Bassett	92
Letters relating to the distribution of vaccine	95
Pseudoscabies, A. W. Bitting	95
The effects of eating moldy corn, A. W. Bitting	94
Composition of bones of sound horse and of bones of horse suffering with osteoperosis, H. A. Huston and A. H. Bryan	96
Material for packing horses' hoofs, H. A. Huston and A. H. Bryan	96
An experimental investigation of a dermatomycosis of fowls, L. Matruchot and C. Dassonville	94

AGRICULTURAL ENGINEERING.

Description of experiment station piggery, H. E. Van Norman	96
---	----

EXPERIMENT STATION RECORD.

VOL. XII.

No. 1.

An interesting step looking to the advancement of agriculture in the Russian Empire has recently been taken, on the recommendation of the Ministry of Agriculture and Imperial Estates, in the inauguration of a system of commissioners of agriculture to preside over the agricultural affairs in their respective provinces or governments, and to seek to promote and improve the agricultural conditions in general. Provision has been made for such commissioners in 20 different governments of the Empire, and the appropriation for their maintenance became available with the beginning of the present year. These commissioners will correspond in a general way to our State commissioners of agriculture or secretaries of State boards of agriculture. They will have charge of all public measures relating to agriculture and rural affairs, and will exercise supervision over all local agricultural institutions maintained by the government. They will inquire into the agricultural needs of their respective governments, and will recommend government aid for such local or private enterprises as merit special encouragement.

The commissioners will likewise be charged with the administration of the system of government loans on agricultural improvements and bounties for the encouragement of farm industries. They are expected to take an active part in provincial and municipal agricultural meetings, and to maintain close relations with all societies and conventions of agriculturists.

Connected with the commissioners' offices will be corps of agricultural specialists and instructors, who will be assigned to the work by the Ministry of Agriculture and Imperial Estates. They will go out among the landowners and peasants for the purpose of collecting data regarding the actual conditions of various branches of agriculture, to diffuse general information on agricultural topics, and endeavor to improve the methods and practices in vogue. At the request of farmers they will visit their farms to give expert advice on questions of management, and they will take active measures for the repression of insects, injurious animals, and plant diseases.

The Ministry of Agriculture will cooperate with these various agencies by the issue of manuals and other publications, and the com-

missioners will recommend to the ministry such measures for the promotion of agriculture and the improvement of the agricultural conditions in their respective governments as seem to them desirable.

The inauguration of this system would seem to be a distinct mark of progress. Taken in connection with the recent decrees regarding the establishment of additional agricultural experiment stations and systems of agricultural education, already referred to, it should materially improve and modernize the practice of agriculture in Russia.

The last appropriation act for this Department carried provisions for the inauguration of experiment stations in the islands of Hawaii and Porto Rico. In accordance with this the preliminary steps have been taken to determine the best plan of operation in each case and the subjects which are in most need of immediate attention.

Prof. S. A. Knapp, of Louisiana, who for a considerable number of years has been engaged in subtropical agriculture on an extensive scale, was selected to investigate the agricultural conditions and possibilities of Porto Rico. Professor Knapp went to the island early in June. In general he will study the present agricultural conditions existing in Porto Rico, the lines of experimental investigation which should be undertaken there, especially in the immediate future, and the locations suitable for stations, together with the approximate expense of inaugurating and maintaining the work of the stations. He will also look into the feasibility of undertaking cooperative experiments with the residents of Porto Rico, and the best means of reaching the people through different classes of publications, demonstration experiments, and otherwise.

For the preliminary survey of the conditions in the Hawaiian Islands, Dr. W. C. Stubbs, director of the Louisiana Experiment Stations, has been selected as especially fitted by experience. Dr. Stubbs sailed for Hawaii about the middle of July, and will spend the month of August in the islands. The conditions there with reference to station work are different from those in Porto Rico, as a station for experiments in sugar production has been maintained by private beneficence for a number of years. In connection with his investigation of the location of a station, Dr. Stubbs will consider the feasibility of combining the Federal station with the Hawaiian Experiment Station or the agricultural department of the Kamehameha Manual Training School at Honolulu. Here also the lines in which investigation is most needed, the possibility of greater diversification of the agriculture, the expense of inaugurating and maintaining experiment station work, and the means of disseminating information among the people will be carefully inquired into. This will probably prove a profitable field for investigations on the use and economy of water in irrigation, since according to reports received from authentic sources, in no other place

is so much money expended for pumping water for irrigation. Some of the pumps are said to be raising 30,000,000 gallons of water per day from a depth of 500 feet, using coal that costs \$10 a ton. The expense of irrigating in some cases reaches as high as \$125 per acre annually.

Preliminary reports will be rendered by Professor Knapp and Dr. Stubbs early in September, in order that the necessary steps may be taken for inaugurating the work as far as the appropriations for this year will allow, and the estimates made for another year. Detailed reports will be presented later in the fall. It is hoped that these reports, by two men so well qualified to judge of the situation, will enable the Department to institute station work in these new possessions on a basis which will secure the greatest direct benefit to their agriculture.

NOTES ON HORSE FEEDING.

E. LAVALARD,

Superintendent of Conferences at the National Agronomic Institute.

For many years the writer has conducted investigations on the feeding of horses for the *Compagnie générale des omnibus de Paris*, with the object of establishing a rational basis for the feeding of horses under different conditions of work. The investigations have covered saddle horses and light draft horses traveling at a rapid gait, horses hauling light loads, and finally heavy draft horses hauling heavy loads at a slow pace. Some years since, the author's earlier work along these lines was included in a treatise on horse feeding.¹

In these notes no attempt will be made to discuss the principles which regulate the nutrition of horses. This subject has been well treated by Chauveau and his pupil Laulanie; by Duclaux, director of the Pasteur Institute; by A. Gautier, and others in France; and by von Mering, Zuntz, and Wolff, in Germany. All who are interested in investigations on horse feeding are familiar with the experiments of Boussingault; of Baudement, on the horses of the Versailles garrison; of Hoffmeister at the experiment station of Weende, and of E. Wolff, W. Finke, and O. Kellner; and also with the late experiments made in France by Grandeau and Leclerc for the *Compagnie générale des petites voitures*, and those undertaken by the author for the *Compagnie générale des omnibus de Paris*, with the cooperation of A. Müntz,² director of the laboratories of the National Agronomic Institute. The special purpose of the present paper is to discuss the practical side of horse feeding, especially the methods employed to maintain, in a satisfactory state of efficiency and health, horses which are required for any definite kind of work—methods which the author has tested repeatedly with army horses and others. No reference can be made to the analytical side of these investigations.³

¹Le Cheval. Dans ses Rapports avec l'Economie Rurale et les Industries de Transport. 2 vols. Paris: Firmin-Didot et Cie. Some of the author's recent work is summarized in Compt. Rend. Congrès Soc. Aliment. Rat. Betail, 1 (1897), p. 60.

²The greater part of the recent investigations on feeding of horses has been noted in the volumes of the Experiment Station Record. The earlier work in which a balance of income and outgo was made is summarized in Office of Experiment Stations Bul. 45.

³For details of this phase of the investigation see articles by Müntz, Ann. Inst. Nat. Agron., 1877-78, No. 2, p. 51; 1878-79, No. 3, p. 23; No. 4, p. 75; 1879-80, No. 5, p. 195; 1883-84, No. 9, p. 71.

MEASUREMENT OF THE WORK PERFORMED BY HORSES.

The chief aim in horse-feeding experiments is to learn the amount of nutrients which the animal body, considered as a machine, requires for work. This requires an estimate or measurement of the amount of work performed. Such measurements in the case of draft horses can readily be made with a dynamometer. The measurement of the energy expended by a saddle horse, however, is a different matter. In the opinion of cavalry officers who have studied this question, measuring the distance covered and the rate of speed is practically the only method available. According to Marcy, who has devoted considerable attention to the subject, the work accomplished in a given time is proportionate to the square of the velocity. His coefficients were 3.42 for walking or pacing, 16 for trotting, 28.62 for cantering, and 68.39 for a full gallop. That is to say, $4\frac{1}{2}$ times as much work is performed when trotting as when walking, $1\frac{3}{4}$ times as much when cantering as when trotting, and $2\frac{1}{2}$ times as much when on a full gallop as on an ordinary gallop or canter. These are only general statements, and it is impossible as yet to calculate the actual energy expended by saddle horses carrying their riders at different gaits.

It has been suggested that it may be possible to gain an idea of the energy expended by noting the number of pulsations of the flank, which has been found to vary with the gait and with the grade and character of the surface passed over. It is evident that in the case of saddle horses, useful work depends largely upon the speed, since the quantity of work of which the animal is capable diminishes with increased speed. In the same way it has been found with draft horses that the period for which work can be continued diminishes as the speed increases. The conditions under which the work is done are also of importance. External temperature may be mentioned, as well as the conditions of the surface traveled over, the skill of the driver, the methods of harnessing, and the load which must be drawn. Poncelet estimates that a horse carrying a weight of 120 kg. and traveling at a speed of 1.1 meters per second for 10 hours per day performs 4,752,000 kilogrammeters of work. When the weight borne equals 80 kg., the same horse trotting at the rate of 2.2 meters per second for 7 hours per day performs 4,435,000 kilogrammeters of work.

Ellenberger estimates that the Prussian cavalry horse performs 1,500,000 kilogrammeters of useful work daily during the winter months, when less is required of horses than at other seasons. In the spring and summer the preparation for the military maneuvers increases this quantity 200,000 kilogrammeters daily. According to the same author, when a horse travels from 24 to 34 kilometers per day and carries a load of 110 to 125 kg., the energy expended is equivalent to from 300,000 to 500,000 kilogrammeters of work. These

values are naturally still further increased during the military maneuvers. Poncelet's figures are almost the same as Ellenberger's.

In order to determine the distance traveled, the data furnished by Colin are used. A saddle horse walking a kilometer in 10 minutes travels at a speed of 1.66 meters per second. Trotting a kilometer in $4\frac{1}{4}$ minutes, an average speed in the opinion of cavalry officers, he travels 3.92 meters per second. Colin found that the average speed of a trotting horse was 2.72 meters per second. The first value must refer to a full gallop, and the latter value seems to be a fairer estimate. Using this and following Poncelet's method, the amount of work performed by a horse in a day is expressed by the following formula: $P \times V \times T = PVT$ kilogrammeters, in which V = mean velocity in meters, P = mean exertion in kilograms, and T = time. Of course these values necessarily have limits. Thus the limit for T is estimated by Poncelet at 18 hours; that for P , 3 to 5 times that which produces a maximum of effectiveness, and V at 12 to 15 times the velocity best suited to the production of work with the horse under consideration. These values are worth noting, but can not be accepted as final, and there is much disagreement concerning the proper values. It is, however, generally admitted that T is diminished in proportion as $P \times V$ is increased. Race horses furnish a striking illustration of this. Applying the above values to the army horse, which travels more regularly than the others, and assuming that the average rider weighs approximately 80 kg. without a pack and weighs 120 kg. with, the calculated amount of work performed would be as follows:

Work performed daily by an army horse.

	Weight carried.	Velocity per second.	Work per sec- ond.	Duration of daily work.	Total of work at different gaits.	Total daily work.
	<i>Kg.</i>	<i>Meters.</i>	<i>Kgm.</i>	<i>Hrs. Min.</i>	<i>Kgm.</i>	<i>Kgm.</i>
Ordinary work:						
Walking	80	1.66	132.8	2 30	1,195,200	} 2,361,600
Trotting	80	2.75	216.0	1 30	1,166,400	
Roadwork:						
Walking	120	1.66	199.2	1 30	1,074,600	} 2,867,400
Trotting	120	2.75	322.0	1 30	1,792,800	
Military maneuvers:						
Walking	90	1.66	149.4	2 00	1,072,800	} 3,740,400
Trotting	90	2.75	247.5	3 00	2,667,600	

It will be seen that using Poncelet's formula we do not obtain his values, namely, 4,752,000 kilogrammeters for a horse walking 10 hours, carrying a load of 120 kg., and 4,435,000 kilogrammeters for a horse carrying a load of 80 kg. and trotting 7 hours.

The values noted above undoubtedly show something of the labor expended, but are far less exact than results obtained with a dynamometer. With artillery horses and those in the train, the problem becomes much more complicated, since these horses draw a load and

also carry a rider. Further, the traction is not performed under the same conditions as with ordinary vehicles. The artillery horse travels over such varied surfaces that the rate of speed can not be calculated even approximately. According to some of the writer's experiments, the coefficient of speed of gun carriages and caissons is 2 per cent on roads, 6 to 8 per cent on fallow lands, and 12 per cent on wet, plowed fields.

In view of these difficulties, it is evident that the only means of obtaining at all satisfactory results is to estimate the load carried and hauled per horse over the total distance. The writer's observations on this subject were made with 16,000 horses of the *Compagnie générale des omnibus de Paris*, 17,000 army horses, and about 1,000 horses used for hauling heavy wagons. The experiments have extended over a number of years. The horses of the *Compagnie générale des omnibus* were of nearly uniform size and weight. Those in the army differed in size and weight. In all these tests the weight of the horse has been relied upon as showing whether the ration was satisfactory for the work performed.

The 20,000 or 30,000 horses experimented upon were maintained in good condition, and performed the required work without any noticeable loss of weight, and further the horses still possessed great reserve energy. The numerous weighings which have been made in the progress of these investigations have enabled the author to determine quite accurately what should be the weight of a good horse in perfect health under various conditions of work or rest, taking into account, of course, age and size. In the present paper it is necessary to omit details, but the table below shows the average weights of different kinds of horses in our experiments:

Average weight of horses.

	Kilograms.
Heavy draft horses	700-800
Light draft horses	500-600
Fancy horses, reserve cavalry horses, and horses of the line...	450-510
Carriage horses and light cavalry horses	380-400
Artillery and train horses	480-495
Mules	430

It is on the basis of such data that the rations have been varied, according as the horses gained or lost weight.

FOOD REQUIREMENTS OF HORSES.

In connection with the experiments a large number of analyses have been made of food, urine, and feces, and the coefficients of digestibility of many feeding stuffs were determined. The object of our experiments has been to determine the quantity of protein, fat, carbohydrates, and mineral matter necessary for maintaining a horse

of any given weight when no work was required except that for motion of forward progression, and also when work was performed. It was also necessary to measure the amount of work as accurately as possible.

It is interesting to note that as shown by the experiments the longer the period of proper feeding the more satisfactory the production of work. This explains why it is better to depend on rations which build up the body and put the animal in good training, rather than on those fed at the time when the work must be performed. In connection with the investigation of army horses attention has frequently been called to the false economy practiced during periods when the horses had little work to do.

As a result of our investigations, we conclude that a horse performing ordinary work requires 115 gm. of digestible protein and 1,100 gm. of digestible carbohydrates per 100 kg. live weight. When severe work is performed, as during military maneuvers, marching, or in time of actual war, the protein should be increased to 135 gm., the carbohydrates remaining the same. In arriving at this deduction it has been necessary to proceed slowly and make many tests, for the figures given by Boussingault, Baudement, and Wolff did not furnish sufficient data for calculating the necessary standard rations. On the other hand, the rations finally adopted do not differ very greatly from those which have been suggested by experience. It is not surprising that the published statement of the results of our latest investigations differ somewhat from those conducted in 1888, since experimental and analytical methods have been greatly improved, and in all the later calculations digestible nutrients only have been considered.

If the weight of the horse and the chemical composition and digestibility of the feeding stuffs are known it is an easy matter to compute standard rations. The following table, showing the maintenance ration for army horses and mules, is an illustration of such calculations:

Maintenance ration for army horses and mules.

	Peace footing.		War footing.	
	Oats.	Hay.	Oats.	Hay.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Cavalry horses, reserve.....	5,900	4,000	6,670	4,000
Cavalry horses, line.....	5,200	3,500	6,140	3,500
Light cavalry horses.....	4,700	3,000	5,335	3,000
Horses of artillery and train.....	5,600	3,850	6,440	3,850
Mules.....	4,900	3,400		

The calculation was found even more satisfactory with heavy draft horses, since the weight of individual horses differs less from the average weight than in the case of the smaller animals. For instance, a draft horse weighing about 700 kg. would require, for ordinary work, 805 gm. digestible protein on the basis of 115 gm. per 100 kg. of live

weight, or 945 gm. for more severe work on a basis of 135 gm. per 100 kg. live weight. The same amount of carbohydrates would be required in both cases. At the rate of 1,100 gm. digestible carbohydrates per 100 kg. of live weight the necessary amount would be 7,700 gm. The amounts of protein and carbohydrates called for in these two cases would require 9 to 9.5 kg. of oats and 5 kg. of hay. No account is taken of the straw supplied for bedding, though the little that would be eaten would, of course, supply a small amount of nutrients. The digestible protein and carbohydrates in 9 kg. of oats and 5 kg. of hay is shown in the following table:

Digestible nutrients in a ration of oats and hay.

	Digestible protein.	Digestible carbo- hydrates.
	<i>Grams.</i>	<i>Grams.</i>
Oats (9 kg.)	675	5,780
Hay (5 kg.)	210	2,268
Total.....	885	8,048

As has been stated, one of the principal objects of our investigation has been to establish the ration of grain and coarse fodder on the basis of the amount of work required. The owners of post horses in early times increased the ration of oats whenever the relays were less frequent, and hence the distance traveled was greater than usual. While such changes were empirical, it may be said that in general all the post horses used on the mail and stage coaches before the opening of railroads were fed rations proportionate to the amount of work required of them. It was found necessary to allow these horses to rest at intervals, not on account of the ration fed, but from the fact that they were usually driven beyond their normal speed. A possible reason for this may have been that they were not as highly bred as draft horses of the present time. During these periods of rest the horses were worked on farms at a slow gait. No scientific estimate had been made of the work expended in hauling a heavy stage or mail coach at a rapid gait.

The difficulties in the way of accurately estimating the work performed by horses constitute the chief reason why we adopted the plan of proportioning the amount of nutrients fed to the weight of the animal. If the weight diminishes it is because the food supplied is not sufficient for the energy expended. It was stated above that the weight of large horses of uniform size was less variable than that of small horses. In 1851 Baudement noted that the largest and heaviest horses apparently derived the greatest benefit from a uniform ration. According to his explanation this was not because they made better use of a uniform ration than smaller horses, but because their losses in

weight were actually less in proportion to their size. The physiological reason for this, Baudement believed, is that large horses, other things being equal, actually change in weight less readily than small horses, since the organs of secretion and the surface area (which serves for the radiation of heat) do not vary regularly in proportion to size, but are relatively larger in animals of small size, and do not perform their functions as economically in small as in large animals. The writer's observations have led to the same conclusions. This theory shows why somewhat larger amounts of protein and carbohydrates are considered necessary per 100 kg. live weight with small horses than with large ones, and also why small animals are often given rations especially rich in protein.

Although the standard rations suggested are based on a very large number of estimates, they should be considered the minimum amounts which will keep horses in condition and prevent premature wearing out. Chardin, an army veterinarian and the author of a recent work on army horses,¹ gives estimates which are smaller than ours. They are in effect as follows: It is probable that the average daily work performed by army horses is about 700,000 kilogrammeters. According to the investigations of A. Sanson, 1 kg. of protein combined, as it should be in a satisfactory ration, with 5 to 6.5 kg. of carbohydrates, would supply 1,600,000 kilogrammeters of energy; hence 700,000 kilogrammeters would require the consumption of 437.5 gm. of protein. Oats contain on an average 12 per cent of protein. Therefore 3,645 gm. of oats would be required in order to furnish the necessary 437.5 gm. of protein. As a general rule, the rations of French army horses contain about 800 gm. in excess of this amount, as is shown by the official statistics published by the French Government in 1887. On the other hand, the quantity of hay supplied is about 2 kg., or one-third less than it should be. It must be remembered that so far only external work has been considered. The internal muscular work must also be provided for. The surplus amount of oats mentioned serves for this but is not quite sufficient, and the deficiency is made up by the straw consumed. This also serves a useful purpose in another way. It increases the bulk of the ration. It is not certain, however, that sufficient straw is consumed.

This summary shows the difficulties of the problem under consideration. It is the writer's opinion that his values are more nearly proportional to the actual requirements than those of Chardin.

Turning to the investigations which have been made on this subject in Germany, we find that Ellenberger's researches led to an increase in the grain ration supplied to the army horse. The author recently had the opportunity of personally becoming familiar with the investiga-

¹ *Hygiène du cheval de guerre.* Paris: Asselin & Houzeau, 1898.

tions of Zuntz and Lehmann (E. S. R., 7, p. 545). In experiments with the light cavalry horses of the German army (estimated to weigh, on an average, 450 kg.) these investigators arrived at results identical with those obtained in our experiments with horses of the line. The principal object of Zuntz and Lehmann's investigations, which were made with horses at rest and performing muscular work, was the determination of the amount of oxygen consumed and carbon dioxide produced in a unit of time, *i. e.*, the respiratory quotient. In their calculations these authors have assumed that in general cavalry horses perform two-thirds of their work trotting and one-third walking, and that in ordinary weather the ground passed over is fairly even, firm, and springy. They divide the year into three periods: The first of 150 days of work and 31 of rest, the second of 65 days of work and 29 of rest, and the third of 67 days of work and 23 of rest. The first period corresponds to the winter season, during which the horses travel on an average about 15 kilometers per day; the second to a period devoted to drilling, during which they travel about 30 kilometers per day; and the third period to the time of the military maneuvers, when they travel about 60 kilometers per day. The corresponding amounts of work are calculated on the supposition that in the first period the horses each carry a weight of 82 kg.; in the second, of 90 kg.; and in the third, of 110 kg. Zuntz and Lehmann compared the rations supplied in the German army with the work required in the third period, and came to the conclusion that they were quite insufficient. They believe that in order to make good the loss entailed by this work, 1,718 gm. of oats should be added to the daily ration, which at present consists of 5,400 gm., and that it would be profitable to make this addition throughout the entire year and not simply during the time of the maneuvers.

It is interesting to note that these German scientists, using laboratory methods, obtained practically the same results as the author with experiments of a different character, but made upon a very large number of horses.

PREPARATION OF FEED FOR HORSES.

Some of our recent experiments have had to do with the methods of feeding. They cover a number of points. The first and perhaps the most important is the advantage of cleaning the grain. Grandeaue showed in his experiments at the laboratory of the *Compagnie générale des voitures* that oats could be satisfactorily freed of foreign grains and impurities by some of the well-known screening devices. He studied the composition of the impurities, and found that some of them were injurious to the health of horses.

The importance of proper cleaning is illustrated by a point in our own experience. A few years ago, after a very severe drought, we

were compelled to feed oats containing tares and leguminous seeds, some of which were those of species of *Lathyrus*. Symptoms of *Lathyrus* poisoning were noted in a number of horses. The attacks were frequently severe and sometimes fatal. When the oats were properly cleaned this trouble was entirely obviated. Cleaning also increases the density of the oats by removing mineral matter and dust, which may sometimes induce attacks of intestinal obstruction, colic, etc.

Contrary to the opinion of some experts, the writer believes it is not necessary to grind grain for horses. This is especially true in the case of oats. It does not appear that the advantages gained by grinding are sufficient to cover the cost of the operation. In some of our earlier experiments, where ground grain was fed, it was noticed after a few months that the horses preferred to crush it themselves. Of course this does not refer to old horses. They can be fed ground grain to advantage.

For the past four or five years we have chopped coarse fodders, using a ration of equal parts of hay and straw, and have found this practice the most profitable for several reasons: Straw may thus be made to form an integral part of the ration, and the proportion of hay and straw may be accurately regulated. Furthermore, horses waste much less of such fodder, especially if some material other than straw is used for bedding. Experiments are now in progress under the author's direction with whole and chopped fodders, to study the comparative cost, the most favorable conditions, and the nutritive value of chopped fodder. As yet somewhat contradictory results have been obtained and the experiments must be continued before definite conclusions can be drawn. It may be said with certainty, however, that the feeding of chopped fodder has brought about a considerable saving and permitted greater uniformity than was previously the case in our experiments.

GRAIN FEED FOR HORSES.

In all that has been said above only oats, hay, and straw have been considered, and there are many who maintain that a ration must be made of these articles, especially for army horses. In Europe this prejudice is deep seated. Even if other grains are used for draft horses, oats are regarded as indispensable for saddle horses, carriage horses, etc. Of course in America corn is abundant and ideas and practice concerning its use are different from those which prevail in Europe.

Many analyses, made in connection with our investigations extending over 30 years, have shown that native French oats and foreign oats, with few exceptions, contain about 10 per cent of protein and this value is used in all our calculations. Smaller variations have been observed in the fat and carbohydrate content of oats, and 4.7 per cent

represents about the average for fats and 69 per cent for the carbohydrates (including cellulose).

The writer will endeavor to show that it is possible to substitute other grains for oats and at the same time maintain horses of all kinds in proper condition.

It is frequently said that oats contain a stimulating principle, which has been given the name "avenine," and the energy which race horses manifest has been attributed to this. We do not believe in this theory, and our attempts to discover this body have been fruitless.

The oat kernel is surrounded by a tough hull, and owing to its physical condition is, weight for weight, less nutritious than other grains. The oat hull constitutes from 25 to 30 per cent of the total weight of the grain, and is not very digestible or nutritious. A proof of this is the fact that hulls are almost always recovered whole in the feces. In the digestion experiments published in full in a previous article, the weight of the hulls is noted, and it appears that only about two-thirds of the total weight of the oats is digested.

Formerly other grains were seldom substituted for oats, especially in France, except when oats were very high in price. To-day such substitutions are much more common.

Not only may single grains and other single foods be substituted for oats, but more or less complex mixtures may be used as well. We believe that both from a hygienic and an economic standpoint our experiments have settled this matter, which has provoked so much discussion. An examination of the statistics we have gathered in the last 35 years shows that although a great saving has been effected, it has not been at the expense of the productive power of the horses. The Germans have also begun to substitute different feeding stuffs for oats, and in some cases they have gone so far as to use mixtures of peat and molasses.

Boussingault was perhaps the first to suggest the idea of substituting other materials for oats in the ration of farm horses. With this end in view he devised a table of nutritive equivalents, using hay as a unit. However, since the composition of hay varies within such wide limits, this method is hardly practicable. More recently tables showing the average composition of feeding stuffs have been provided from which the amounts of protein and carbohydrates in any given ration can be calculated. Analyses of the locally grown feeding stuffs are considered preferable. Other materials should be substituted for hay or oats on the basis of their composition, otherwise too much protein may be given, with injurious results, as, for instance, when alfalfa is substituted for ordinary hay, pound for pound.

The principal substitutes for oats are Indian corn or maize, barley, horse beans or other beans, rye, and wheat. The special characters of each deserve some attention.

Indian corn.—Our first experiments in this line were made with Indian corn. They were undertaken with all kinds of horses and gave most satisfactory results. The *Compagnie générale des voitures* and the *Compagnie générale des omnibus* began about 1870 to feed Indian corn, and the results were so satisfactory that since that time the first-named company has almost entirely ceased to feed oats. The latter company has continued to feed both oats and corn, effecting a saving of from 1,000,000 to 1,500,000 francs per year. In view of these facts the opponents of corn have been forced to admit that it is a suitable feed for draft horses. They have insisted, however, that since it does not contain the so-called stimulating principle “avenine” it should not be used for saddle horses and others where speed is required. Examples of the successful use of corn were cited in the author’s earlier publications. The horses of the French expedition in Mexico were fed exclusively on corn. Our recent experiments on cavalry and artillery horses have shown that Indian corn may generally replace oats without in any way causing the horses to deteriorate. The horses fed the corn ration were used the same number of hours in the military drill and in the maneuvers, and were ridden at the same gait as those fed exclusively on oats, and it was practically impossible to perceive the least difference between the two classes. The army officers, prejudiced as they naturally were, were forced to admit that all the horses showed the same energy and vigor. A careful record showed that the sickness and mortality were the same with horses on the two rations.

Corn and oats are quite similar in composition. In experiments made at the laboratory of the *Compagnie générale des omnibus* in cooperation with Müntz the author found very high coefficients of digestibility for corn, as shown by the following results: Protein 86.1, fat 93.9, sugar and starch 100, crude fiber 82.8, saccharifiable fiber 86.9, undetermined substances 85.2 per cent. These coefficients show that the nutritive ingredients of corn are much more assimilable than has been generally believed in Europe. As regards physical character, oats contain on an average 70 to 75 per cent of kernel and 25 to 30 per cent of indigestible hull, which resembles straw in composition. The skin or hull of maize amounts to practically nothing. These facts show why horses thrive better and are more apt to maintain their weight on corn than on oats. Our recent experiments have demonstrated that corn can replace oats in the ration of both cavalry and artillery horses, and if substituted weight for weight it increases the nutritive value of the ration. This is the same deduction which was drawn from the experiments, now more than 25 years old, made for the two great cab companies of Paris.

Barley.—Although it is well known that barley can replace oats and indeed is a staple feeding stuff for horses in Italy, Algeria, Spain, and other countries where oats can not be raised profitably, experiments

were undertaken in the laboratory of the *Compagnie générale des omnibus*, and especially in connection with the investigations conducted with army horses, to study the circumstances under which the substitution can best be made. It has been often asserted that barley is not as rich in protein as other cereal grains. Our most recent analyses seem to establish this fact. However, barley is one of the grains whose composition is very variable, being noticeably influenced by the system of cultivation followed.

For 20 years we have been feeding barley to horses. In the experiments with saddle horses and draft horses we use the following values as representing the average composition of barley: Water 12.93, protein 8.83, fat 1.43, carbohydrates 73.66, and ash 3.1 per cent. Certain kinds of barley of good quality showed on analysis from 9.37 to 11.87 per cent of protein. The coefficient of digestibility of the protein of French barley is 80.13, of African 71.07. The coefficient of digestibility of carbohydrates of French barley is 66.24, of African 62.14. The general practice is to substitute barley for oats, weight for weight. In our experiments we followed this custom, but soon observed that the horses fed barley lost weight. It was therefore necessary to increase the quantity of barley in order to supply the same amount of protein and carbohydrates as in the oat ration. When this change was made, the horses regained and preserved the same physical condition as those fed oats. In general it may be said that only barley of good quality should be fed. The barley bran is very tough, and we have noticed that when barley of poor quality is fed the feces contain as much as 4.2 per cent of undigested material, while the feces of horses fed barley of good quality contain scarcely any undigested grain.

In conclusion, barley can replace oats, but a slightly greater amount must be fed. This is especially true when rations are calculated as closely as is the case with army horses.

Horse beans and other beans.—The experiments made many years ago for the Paris cab companies warrant the statement that when beans replace oats only half the quantity should be used. Tests made with army horses have confirmed this conclusion. The chemical composition of beans shows why they are regarded as more nutritious than oats alone. Beans may be advantageously fed to horses required to perform long continued, sudden, or severe labor. The opinion is prevalent in England that in hunting it is always possible to recognize horses fed beans by their great endurance. In accord with the practice of the leading racing stables, we used a large proportion of beans in the ration of young horses which were being trained. The results obtained were most satisfactory.

As shown by our numerous analyses, beans have the following average percentage composition: Water 18.07, protein 24.44, fat 1.06, nitrogen-free extract 48.20, crude fiber 6.05, and ash 2.7. The average

coefficient of digestibility of protein of beans was found to be 89.3 and of the extractives, cellulose, and fat, taken together, 73.3 per cent.

In our experiments with draft horses and saddle horses, we have not replaced more than 1 to 2 kg. of oats by an amount of beans supplying an equivalent amount of digestible protein and carbohydrates. It should be said that when beans replace oats there is usually an excess of protein and a deficiency of carbohydrates. This furnishes a reason for the common practice of adding straw or other coarse fodder containing little protein to such rations.

Rye.—The Paris cab companies have always fed some rye, especially when this grain was cheap. We tested it also in experiments with army horses. Rye was substituted for oats, weight for weight, and the amount gradually increased until the horses maintained a constant weight. In tests with draft horses, greater latitude was possible in substituting rye for oats, weight for weight, since the ration is always sufficiently large to cover any discrepancies. The utmost precautions were taken to prevent the introduction of ergotized rye, which, as is well known, may cause serious disturbances.

The average percentage composition of rye is: Water 14.5, protein 9.99, fat 1.29, nitrogen-free extract 70.88, crude fiber 1.38, and ash 1.95; the average coefficients of digestibility are: Protein 73.97, fat 54.05, and nitrogen-free extract and crude fiber together 75 per cent.

Our experiments with rye have furnished less definite results than with other grains. We believe this is due to the fact that the value of rye is more influenced by the variation in composition of the grain and by individual peculiarities of the subject. In former times the feeders of post horses obtained contradictory results with this grain, which they usually attributed to the methods of feeding it. In some countries rye is fed cooked and this method proves entirely satisfactory. It is mixed with oats in the proportion of 1 of rye to 3 of oats, or when cooked, in the proportion of 1 to 3 or 1 to 2. Several years ago we fed rye and oats to the horses of the *Compagnie générale des omnibus* in the proportion of 1 to 4, with entirely satisfactory results, and with an important saving in cost.

Wheat.—Experiments were also made in which wheat was substituted for part of the oats in the daily ration of horses. It is well known that such a mixture is fed by horse breeders when unusual service is required of the stallions. In view of the accidents which have been known to follow feeding wheat, we have taken the utmost precautions in our experiments. It may cause an irritation or itching of the skin so that the horses suffer greatly. This is similar to the effect produced by buckwheat.

A complete survey of the subject of substituting other materials for oats in the ration of horses would necessitate the discussion of such concentrated feeds as bran, barley meal, carob beans, linseed cake, sesame cake, palm cake, cocoa cake, starch cake, maize cake,

cakes from distillery refuse, and other commercial cakes. Our recent tests have added nothing to the deductions drawn from our earlier experiments with these materials. It may be positively stated, however, that the chemical composition and digestibility of any of these feeding stuffs determines the proportion which may be substituted for oats, and that the composition and digestibility of all of them may vary within wide limits. Following the methods that we have used, we believe it is quite possible to devise successful rations for maintenance, transportation, and work.

COARSE FODDERS.

Before closing it seems desirable to add a few words concerning the coarse fodders usually fed with the different grains. In discussing the standard ration it was explained that hay was the principal coarse fodder used, and that straw figured only in an incidental manner. The average composition of hay and straw as shown by our analyses of samples grown in many regions of France is as follows:

Average composition of French hay and straw.

	Water.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Hay.....	12.8	6.68	1.51	47.76	24.76	6.89
Straw.....	13.22	2.86	1.39	41.88	34.74	6.20

These coarse fodders may be replaced in the ration of horses by other fodder plants, such as alfalfa, sainfoin, red clover, etc. This statement is borne out by the recent experiments of Müntz and Girard¹ made with the horses of the *Compagnie générale des voitures*.

The statement is often made that horses can not do without straw. This is an error, for we have fed horses hay and oats during very long periods and have never noticed that they suffered any inconvenience or detriment. This is a matter of importance, since it is often inconvenient to obtain straw, and in such cases peat, sawdust, sand, etc., may be profitably used as bedding in place of straw.

Nothing has been said of the use of green fodders. Such feed, however, is more suited to special conditions and is very dependent upon the fertilizer used for the crop, the method of harvesting, and the condition of the animal fed. Green fodder does not contain sufficient nutritive material to make it in any real sense a feeding stuff for horses performing much work. The same may be said of certain plants which have been much advertised from time to time, such as furze, couch grass, etc.

In an earlier publication the feeding value of carrots, parsnips, rutabagas, beets, and potatoes was discussed. The use of these materials has been attempted from time to time with varying success.

¹Ann. Agron., 24 (1898), p. 5.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The volumetric determination of potash, R. H. ADIE and T. B. WOOD (*Proc. Chem. Soc. London*, 16, pp. 17, 18; *abs. in Chem. Centbl.*, 1900, I, No. 10, p. 572).—In the method proposed the potash is precipitated by means of cobalt nitrite, the precipitate usually having the formula $K_6Co_2(NO_2)_{12} \cdot 3H_2O$. The method is carried out as follows: The potash solution is freed as far as possible from other bases, acidified with acetic acid, and an excess of sodium-cobalt nitrite is added. After 24 hours the precipitate is collected on an asbestos filter, washed with 10 per cent acetic acid, and finally with water. The filter with the precipitate is then boiled in dilute soda solution, filtered, and diluted to 100 cc. Twenty cubic centimeters of this solution is acidified with dilute sulphuric acid and immediately titrated with permanganate solution. It is recommended to add an excess of permanganate and titrate back with potassium iodid and thiosulphate solution.

A new reagent for detecting and estimating nitrites in water, H. ERDMANN (*Ber. Dent. Chem. Gesell.*, 33 (1900), pp. 210–215; *Ztschr. Angew. Chem.*, 1900, No. 2, p. 33; *abs. in Analyst*, 25 (1900), Mar., pp. 81, 82; *Bul. Soc. Chim. Paris*, 3. ser., 24 (1900), No. 9, p. 406).—The reagent used is amidonaphtholdisulphonic acid (1:8:4–6), prepared by nitrating, reducing, and heating with sodium hydroxid the naphthalene trisulphonic acid recently described by the author.¹ The method of procedure is as follows: Mix 50 cc. of the water with 5 cc. of a hydrochloric-acid solution of sodium sulphanilate (2 gm. per liter), and after 10 minutes add 0.5 gm. of the amidonaphtholdisulphonic acid in the form of its acid alkali-metal salt. In presence of nitrous acid a brilliant Bordeaux-red color appears, which attains its maximum intensity in 1 hour. To determine the amount of nitrites present the color is compared with that produced by solution of sodium nitrite of known strength or with a colored paper scale.

Methods for the detection of "process" or "renovated" butter, W. H. HESS and R. E. DOOLITTLE (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 3, pp. 150–152).—The methods employed consist of tests of the curd, which in the case of renovated butter is different from

¹ Ber. Dent. Chem. Gesell., 32 (1899), p. 3186.

that of normal butter. These tests of the curd consist of the appearance of the butter on heating, the comparison of the separated curd freed from fat with the curd from normal butter, and tests for albumin in the filtered butter. The ratio of casein to albumins may also be determined. In the process butter this has been found to be about 8.6 parts of casein to 1 of albumins. This ratio is determined in the curd which has been thoroughly freed from fat. For determining this ratio 50 gm. of butter is dissolved in ether to a clear solution, the ether solution of fat decanted as far as possible, and the remainder filtered through a separatory funnel. The casein remaining on the filter is washed with water and estimated by the Kjeldahl method. The filtrate is made slightly acid with acetic acid, brought to a boil, and the albumins filtered out and estimated by the same method.

“These tests serve to differentiate between genuine butter and process butter as it is now found on the market.”

A comparison of reagents for milk proteids with some notes on the Kjeldahl method for nitrogen determination, A. VIVIAN (*Wisconsin Sta. Rpt. 1899, pp. 179-186*).—A comparative study was made of a long list of reagents for separating the nitrogenous compounds of milk and their decomposition products into distinct groups. The following method of analysis was adopted and used in investigations on the action of ferments on the proteids of milk:

In preparing the extracts for analysis cheese was emulsified by rubbing with warm water, acidified with acetic acid, and boiled. Milk was also acidified with acetic acid and boiled. The same quantities of the filtrates in each case were taken for the different reagents. Determinations were made of the total nitrogen and of the total soluble nitrogen (nitrogen not precipitated by acetic acid and heat). Portions of the extracts were treated with zinc sulphate, tannic acid and sodium chlorid, and phosphotungstic acid, and determinations were made of the nitrogen in the filtrates, the nitrogen in the precipitates being calculated by difference. The nitrogen as ammonia was determined by distilling with magnesium oxid.

In designating the groups of proteids obtained by this method of analysis the following nomenclature was adopted: Nitrogen in insoluble portion (casein, globulin, and albumin—difference between total nitrogen and soluble nitrogen), nitrogen in albumoses (difference between nitrogen in filtrate from zinc sulphate and total soluble nitrogen), nitrogen in peptones by tannin (difference between nitrogen in filtrates from tannic acid and sodium chlorid and from phosphotungstic acid), nitrogen in peptones by phosphotungstic acid (difference between nitrogen in filtrates from phosphotungstic acid and from tannic acid and sodium chlorid), nitrogen in amids (difference between nitrogen in filtrate from phosphotungstic acid and in ammonia), and nitrogen in ammonia.

The distribution of nitrogen in a Cheddar cheese 6 months old was found by this method of analysis as follows: Insoluble portion 3.18, albumoses 0.06, peptones by tannin 0.16, peptones by phosphotungstic acid 0.13, amids 0.86, and ammonia 0.09 per cent.

The following notes are given on the Kjeldahl method as applied to milk and cheese:

"(1) In determining the total nitrogen in milk or cheese it is necessary to boil with sulphuric acid a considerable time after the solution is clear, as it will otherwise froth badly when distilling. With 2 gm. of cheese 3 hours' digestion is none too long.

"(2) In digesting the filtrates from milk in the methods described in this article, they must be watched closely, or they will froth badly when the water has nearly boiled off, and the flame must be turned very low for from a quarter to half an hour.

"(3) The filtrate from zinc sulphate bumps during digestion with sulphuric acid until the water has been driven off. About half a gram of zinc dust added as the flasks are placed over the flame will prevent it.

"(4) In the opinion of the writer, the use of potassium permanganate and potassium sulphid is unnecessary in nitrogen determinations in milk and cheese, and their use has for some time been abandoned. . . .

"(5) [The use of potassium sulphate and mercury for digestion as recommended by Atterberg (E. S. R., 10, p. 605) was tested.] The writer made 50 determinations in which 10 gm. of potassium sulphate and 0.7 gm. of mercury were used in one of the duplicate samples, and the plain Kjeldahl, or Gunning, method in the other. In every case the employment of both reagents shortened the time of digestion from 20 minutes to 1½ hours, according to the substance used."

Chemists' guide for the examination of foods, condiments, commercial products, etc., F. ELSNER (*Die Praxis des Chemikers bei Untersuchung von Nahrungsmitteln, Genussmitteln und Gebrauchsgegenständen, etc.* Hamburg and Leipzig: Leopold Voss, 1900, figs. 182).

Phosphotungstic acid as a reagent for potash, E. WÖRNER (*Ber. Deut. Farm. Gesell.*, 10 (1899), pp. 4-6; *abs. in Chem. Centbl.*, 1900, I, No. 9, p. 517).—The use of a 10 per cent solution of commercial crystallized phosphotungstic acid is recommended for the detection of small amounts of potash. In neutral or acid solutions of potash salts this reagent produces a white precipitate.

Substitutes for hydrochloric acid in testing carbonates, J. W. RICHARDS and N. S. POWELL (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 3, pp. 117-121).—Acid potassium sulphate, oxalic acid, citric acid, and tartaric acid were tried as substitutes for hydrochloric acid in producing effervescence with natural carbonates in the field. Tartaric acid was found to be the best of the reagents tried, and citric acid nearly as good, both giving satisfactory results.

The volumetric determination of magnesia, J. O. HANDY (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 1, pp. 31-39).

On the determination of carbon and hydrogen by combustion in oxygen, using copper oxid, C. F. MABERY and W. R. CLYMER (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 4, pp. 213-218).

On the determination of ammonia and nitrogen, A. VILLIERS and E. DUMESNIL (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 9, pp. 573-576; *Bul. Soc. Chim. Paris*, 3. ser., 23 (1900), No. 7, pp. 253-256; *abs. in Chem. Centbl.*, 1900, I, No. 13, p. 731).—The organic nitrogen is converted into ammonia and the ammonia expelled by boiling with alkali as in the Kjeldahl method. Instead of titrating to determine nitrogen, however, the acid solution is evaporated to dryness and the ammonium chlorid weighed.

On the detection of nitrous acid in water by means of amidonaphtholsulphonic acid according to Erdmann, H. MENNIGKE (*Ztschr. Angew. Chem.*, 1900, pp. 235, 236; abs. in *Chem. Centbl.*, 1900, I, No. 13, p. 733).—Tests are reported which indicate that Erdmann's method (see above) is a delicate and reliable means of detecting and determining nitrites in water. Some precautions to be observed in manipulation are explained.

The value of methods for detecting nitrites in drinking water, L. SPIEGEL (*Ber. Deut. Chem. Gesell.*, 33 (1900), pp. 639-644; abs. in *Chem. Ztg.*, 24 (1900), No. 32, *Rept.*, p. 113; *Jour. Chem. Soc. [London]*, 78 (1900), No. 450, II, p. 318).—The author tested Erdmann's method (see above) in comparison with various other methods for the same purpose and found it less sensitive than the potassium iodid starch method or the Lunge-Elosvay reagent. The author considers determinations of nitrites in drinking water as of little value, since the nitrites represent a transition stage and their determination may be misleading as to normal conditions. Their detection, however, may be of a negative value, and for this purpose the author recommends the use of guaiacol or creosote, which, in presence of nitrites in dilute solution, give an orange and a yellow coloration respectively. These reactions are not interfered with by the presence of oxidizing agents, such as nitrates, chlorates, and hydrogen peroxid, or by ferric salts in amounts usually met with in potable waters.

On a simple method for determining phosphoric acid in connection with metabolism experiments, A. NEUMANN (*Arch. Anat. u. Physiol., Physiol. Abt.*, 1900, pp. 159-165; abs. in *Chem. Centbl.*, 1900, I, No. 10, p. 571).

Estimating the water in cereals—practical methods, J. F. HOFFMANN (*Wechnschr. Brau.*, 16 (1899), pp. 569-574, 585-588, 605).

The determination of the sugar content of molasses feeding stuffs, A. MENZEL (*Deut. Zuckerind.*, 25 (1900), No. 14, pp. 552, 553).

The preparation of a nonsugar from beet juice, A. RUMPLER (*Deut. Zuckerind.*, 25 (1900), No. 15, pp. 592, 593).

A comparison of some formaldehyde tests, B. M. PILHASY (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 3, pp. 132-135).—Several tests for small quantities were compared. Phenylhydrazin hydrochlorid seemed to be the best reagent. A solution of 1 gm. of phenylhydrazin hydrochlorid with 1.5 gm. sodium acetate in 10 cc. of water was used. To 1 cc. of the liquid to be tested 2 drops of the reagent and 2 drops of sulphuric acid are added, giving a green coloration if formaldehyde is present. In weak solutions (1:10,000 to 1:250,000) take 3 cc. of the liquid and 4 or 5 drops of the reagent and of sulphuric acid, heating if necessary.

Tests for the strength of solutions of formaldehyde, H. A. HUSTON (*Indiana Sta. Rpt.* 1899, pp. 76, 77).—The formaldehyde content of 5 samples of commercial formalin was determined from the specific gravity and by the ammonia and the potassium cyanid methods. The results are tabulated. Brief notes are given on different methods of analysis. The table in Allen's Commercial Organic Analysis used in calculating the formaldehyde content from the specific gravity was not considered applicable to the samples examined.

On Hubl's iodine method for oil analysis, A. H. GILL and W. O. ADAMS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 1, pp. 12-14).

A new method for the determination of fat in dairy products, LINDET (*Ind. Lait.*, 25 (1900), No. 23, pp. 177, 178, fig. 1).—The method depends upon the solubility of casein in a concentrated solution of resorcin. The sample of milk or cheese is treated with a strong solution of resorcin with the addition of a few drops of alkali. This is heated in a water bath until the separation of the fat is completed. The apparatus devised for the purpose consists in part of a graduated cylinder from which the reading for fat is taken. The addition of some coloring matter for clearly differentiating the fat layer is recommended.

Determination of the fat content of milk by the Wollny refractometer, NAUMANN (*Milch Ztg.*, 29 (1900), Nos. 4, pp. 50-53, figs. 7; 5, pp. 66-68, figs. 4; 6, pp. 84-86, figs. 1).—A description of the apparatus and necessary reagents and detailed directions for making the test.

Reducing power of taka-diastrase, H. A. HUSTON and A. H. BRYAN (*Indiana Sta. Rpt.*, 1899, p. 77).—"A sample of taka-diastrase . . . was examined by dissolving 50 mg. of it in 50 cc. of water, adding 20 cc. hydrochloric acid, sp. gr. 1.125, and boiling under return condenser for 2 hours. By this method it was found that 50 mg. of taka-diastrase reduced to cuprous oxid a quantity of copper solution yielding 17.2 mg. of metallic copper."

A new method of standardizing weights, T. W. RICHARDS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 3, pp. 144-149).

Regulations for the testing of thermometers (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 3, pp. 141-149).

BOTANY.

The origin and early development of the flowers of the cherry, plum, apple, and pear, E. S. GOFF (*Wisconsin Sta. Rpt.*, 1899, pp. 289-303, figs. 23). On account of the lack of accurate knowledge as to the formation and early development of the flowers in fruit plants, the author undertook an investigation to ascertain the time of origin and the rate of progress in the flowers of 4 of the most common fruit trees, namely, the cherry, plum, apple, and pear.

The methods of study are described at some length. It appears that the earliest indications of flower in the cherry were in buds taken July 11. In the plum the flower buds appeared as early as July 8. In the apple the first clear evidence of flowers was found in buds taken June 30, and in the pear in buds taken July 21.

The order of development of the various parts of the flower in different fruits seems to be identical. The calyx and receptacle were the first to appear, being developed at about the same time. Next, the stamens and the petals were also formed at nearly the same time, and these were evidently developed as outgrowths from the calyx or from the receptacle. The last to appear was the pistil, and its development was extremely slow. It was noted that the flowers commenced their growth at about the same time that the wood growth ceased. The bearing of this fact upon the production of fruit may be readily understood, since an abundant fruit crop would exhaust the tree to such an extent that the preparation of flowers for the next season would be retarded.

The morphology of the flower bud is described at some length. It was found that an undeveloped bud scale subtends the flower just as the leaf subtends the bud; in other words, the flower occupies the place of a growing branch in the axil of a bud scale. In the apple and pear the terminal flower of the flower bud is most rapidly developed and expands first. The apple-flower cluster, therefore, is a cyme. In

the plum and cherry the proximal flower is developed slightly in advance of the others, and the flower cluster in this case corresponds to the usual definition of a corymb.

Comparative hardiness of flower buds in the cherry, E. S. GOFF (*Wisconsin Sta. Rpt. 1899, pp. 283-288, figs. 2*).—A rather protracted cold period occurred in February, 1899, and on account of the low temperature the effect on flower buds of cherry trees was investigated with considerable interest. Early in April a large number of buds of each variety of cherry grown in the orchard were examined and several important facts brought out. It was found that the central flower buds contained a larger percentage of live embryo flowers than those near the ends of the branches, and the percentage of live embryo flowers increased as the number of flowers in the bud diminished. This was true both on the same tree and in different varieties. But little difference was noted between the hardiness of the basal and terminal buds on the fruit spur.

It is stated that windbreaks would doubtless prevent the destruction of many flowers from the injurious effects of prevailing winds in severe weather, and varieties of Morello species of cherry, in which the number of embryo flowers in the flower bud is comparatively small, are more likely to prove hardy than those in which the number is comparatively large.

Yellow coloring matters accompanying chlorophyll and their spectroscopic relations, C. A. SCHUNCK (*Proc. Roy. Soc. [London], 65 (1899), No. 416, pp. 177-185, pl. 1*).—The author reports on studies made of the yellow coloring matters which are extracted by means of alcohol along with the chlorophyll in healthy green leaves. He concludes that in all crude alcoholic extracts from healthy green leaves 2 yellow coloring matters accompany the chlorophyll; one, chrysophyll, which deposits out of the extracts on standing in lustrous red crystals, often in very small quantity; the other obtained by treating the extract with animal charcoal, the charcoal taking up the chlorophyll and leaving the yellow solution, which deposits on spontaneous evaporation an amorphous substance containing much fatty matter, to which the author has restricted the name xanthophyll. Another yellow coloring matter is sometimes found along with xanthophyll which gives no absorption bands, only an obscuration in the ultraviolet region of the spectrum being noticed. There is also evidence of still other coloring matters which have not yet been separated.

The author believes that xanthophyll is the predominating yellow coloring matter accompanying chlorophyll in the healthy green leaf, and that it is identical with the principal yellow coloring matter occurring in autumn leaves. The absorption bands of the different coloring matters are described at some length.

American grasses—III, F. LAMSON-Scribner (*U. S. Dept. Agr., Division of Agronomy, Bul. 20, pp. 197, figs. 137*).—This bulletin is in continuation of Bulletins 7 and 17 (*E. S. R.*, 9, p. 327; 11, p. 219) of the Division. It contains descriptions of the tribes and genera of North American grasses, with analytical keys. Each genus is illustrated and reference is made to all other species of the genus illustrated in the bulletins just referred to. A bibliography of all the authorities cited in the 3 bulletins has been added.

Notes on useful plants of Mexico, J. N. ROSE (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, pp. 209-259, pls. 16*).—The author records his observations relative to the utilization by the people of Mexico of a number of species of plants.

Studies of Mexican and Central American plants—No. 2, J. N. ROSE (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, pp. 145-200, pls. 8, figs. 30*).—Descriptions of new and notes on little-known species are given, together with a synopsis of the North American species of several groups.

Two new species of plants from the Northwestern United States, L. F. HENDERSON (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, pp. 201, 202, pl. 1*).—Descriptions are given of *Aster latahensis* and *Angelica roscana*.

Hesperogenia, a new genus of Umbelliferae from Mount Rainier, J. M. COULTER and J. N. ROSE (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, p. 203, pl. 1*).—Descriptions are given of a new genus of Umbelliferae, to which the specific name *stricklandi* is given the one species.

Three new species of Tradescantia in the United States, J. N. ROSE (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, pp. 204-206*).—*Tradescantia humilis*, *T. gigantea*, and *T. scopulorum* are described.

Treleasea, a new genus of Commelinaceae, J. N. ROSE (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 4, pp. 207, 208*).—This new genus is separated out of some of the confused material grouped under *Tradescantia brevifolia*, and 3 species are described, *Treleasea brevifolia*, *T. leiandra*, and *T. tumida*.

List of trees and shrubs on the grounds of Purdue University (*Indiana Sta. Rpt. 1899, pp. 136-139*).

New species of fungi from various localities with notes on some published species, J. B. ELLIS and B. M. EVERHART (*Bul. Torrey Bot. Club, 27 (1900), No. 2, pp. 49-64*).—Notes and descriptions on a number of species of fungi, some of which may prove of economic importance, though most are saprophytes or upon plants of little importance from an economic standpoint.

The poisonous and edible fungi of Hungary, G. VON ISTVANFFI (*Die ungarischen essbaren und giftigen Pilze. Budapest, 1899, pp. 20 + 361, pls. 42, figs. 150*).

The position of the fungi in the plant kingdom, H. L. BOLLEY (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 25, pp. 857-859*).—The author argues that if nitrifying organisms are capable of subsisting wholly on inorganic materials, in classification algae should be derived from fungi and not *vice versa* by degeneration.

Studies on the biology of *Penicillium glaucum*, F. P. GUEGUEN (*Tesis, Lons-le-Saulnier, 1899, pp. 83, pls. 5*).

The mechanism of root curvature, J. B. POLLOCK (*Bot. Gaz., 29 (1900), No. 1, pp. 1-63, fig. 1*).

Observations on seasonal dimorphism among plants, WETTSTEIN (*Bot. Centbl., 81 (1900), No. 1, pp. 15, 16*).

On the evolution of carbon and nitrogen in the living world, P. MAZÉ (*Evreux: Hérissay, 1899, pp. 111*).

Evaporation from the young wood of apple trees during winter, A. TRUELLE (*De l'évaporation du jeune bois des pommiers à cidre pendant l'hiver. Alençon: E. Renaut-de Broise, 1899, pp. 24*).

METEOROLOGY—CLIMATOLOGY.

Annual summary of meteorological observations in the United States, 1899 (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review, 27 (1899), No. 13, pp. IX+577-597, figs. 5, charts 5*).—This number of the Review gives a table of contents, list of corrections, additions, and changes; an index for Volume 27; and a summary of observations on atmospheric pressure, temperature, precipitation, wind movement, cloudiness, and other meteorological phenomena “based essentially upon data received from about 150 regular stations [in the United States], 28 regular Canadian stations, and a number of voluntary stations.” It also includes the following special articles: Remarkable aurora at Braidentown, Fla., November, 1899, by H. Ten Broeck; Small seismic changes caused by building operations, by C. F. Marvin; Notes on the climate of Missouri, by A. E. Hackett; Climatology of St. Kitts, by W. H. Alexander (illus.); Rainfall in central and western Nicaragua, by E. Flint; Tables of dew-point observed at Honolulu, by C. J. Lyons; The weather and the live stock industry, by F. H. Brandenburg; and The barograph on shipboard, by J. Page (illus.), and a note by the editor on the meteorological century.

The general climatic conditions of the year 1899 were as follows:

“*Atmospheric pressure.*—In general, the pressure distribution for the year 1899 differs but slightly from that of 1898. Pressure was generally above the normal east of the Mississippi River in both years. It was markedly above the normal over Nova Scotia and the Maritime Provinces of Canada in 1898, and also in 1899, although in a less degree. In the latter year the Atlantic high, as traced by the isobar of 30.05 mean annual pressure, extended several hundred miles farther to the northwestward than was the case in 1898. Pressure on the Pacific coast and Plateau region was slightly lower in 1899 than in 1898.

“On the immediate Gulf coast of Louisiana, Mississippi, and Alabama pressure was from 0.02 to 0.04 in. above normal in both years, while less than 200 miles inland, viz, at Vicksburg, Meridian, and Montgomery pressure was from 0.01 to 0.04 in. below normal. In both years pressure was also below normal from the Texas coast westward to Arizona and southern California. The rainfall of both years was likewise less than the normal amount. In mentioning these facts the writer does not intend to convey the impression that they stand in the relation of cause and effect. The fact that there was an average difference of 0.07 in. in pressure between Vicksburg and New Orleans, 0.04 between Mobile and Montgomery, and the same amount between Atlanta and Jacksonville would seem to suggest rather marked changes in the normal air motions along the Gulf coast.

“In the annual summary for 1898 attention was called to a trough of low pressure which apparently paralleled the foothills of the Rocky Mountains in that year. A similar trough appears on the pressure chart for the current year and the precipitation generally throughout the axis of the trough was above normal as in 1898.

Temperature.—Although the year was characterized by some of the coldest weather experienced within the last 20 or 30 years, the average temperature on the whole was above normal.

“During the greater part of January there were no severe cold waves, but, beginning with the first week in February, the most remarkable cold wave, or series of cold waves, in the history of the Weather Bureau traversed the United States from the North Pacific to the South Atlantic coasts, damaging crops and fruits in the Southern States to a very great extent. The lowest temperatures on record since the beginning of observations were recorded at a number of points in the North Pacific coast States during the first 8 days of the month. From the 9th to the 12th of the month the coldest weather on record was reported at a number of points in the Central, Western, and Northwestern States. During the 13th and 14th a cold wave overspread the Southern and Eastern States, attended on the 13th by the lowest temperatures ever recorded at many points in the Southern and Gulf States. March was a cold, wintry month, and the spring was generally backward, with much snow and unseasonable weather east of the Rocky Mountains.

“In Idaho, Montana, and Wyoming, the western portions of the Dakotas, and Nebraska temperature was below normal for 4 consecutive months, viz, during February, March, April, and May, and also, but in a less degree, during the months of June, July, August, October, and December.

“The summer was marked by an absence of periods of continued high temperature. Very nearly normal conditions prevailed in all parts of the country.

“The fall of the year was generally mild and free from sharp and decided temperature changes.

“Interlake navigation began about the first of May and ended about December 17. The weather in the closing months was quite free from severe storms. . . .

Precipitation.—The precipitation of the year just ended was not evenly distributed. There were 7 separate regions, of greater or less extent, in which more than the normal quantity of rain and snow fell, viz: (1) The Pacific coast from central California to British Columbia, including part of the central and all of the northern Plateau; (2) eastern Wyoming and the Black Hills region of South Dakota; (3) eastern Colorado, Kansas, Oklahoma, and the Panhandle of Texas; (4) northern Wisconsin and the Lake Superior region; (5) southeastern Iowa and central Illinois; (6) a narrow strip of country east of the Appalachians, extending from Augusta, Ga., to Washington, D. C.; (7) the western portion of the Peninsula of Florida.

“Precipitation was markedly deficient in the lower Mississippi Valley, the deficits at the 2 regular Weather Bureau stations in Louisiana being 25 and 29 in., respectively. The rainfall of the Gulf States in 1898 was almost normal, and it seemed at the end of that year that the droughty conditions which had prevailed for a number of years were about to come to an end. The year just closed, however, presents the same marked deficiency in precipitation throughout the Gulf States and Texas that has characterized so many years within the last decade. The cause of the deficiency is not at present known.

Meteorology of the Great Lakes.—The season of navigation was remarkably free from severe storms. . . . The most severe storm of the season occurred on December 11 and 12, at a time, however, when a large number of vessels had gone out of commission.

“The rainfall in the Lake Superior basin was above normal. The snowfall of the winter and spring months was rather heavy not only in the Superior basin but also on the northern shore of Lake Huron, particularly in the Georgian Bay region. On the other hand, precipitation was generally below normal in the basins of Lakes Erie and Michigan, and also over those portions of the watersheds of Lakes Huron and Ontario lying within the boundaries of the United States.

“There was less fog reported during the season of 1899 than during the previous season. The most fog was observed over the central portion of Lake Superior.

"A large amount of ice formed on the lakes during the winter of 1898-99, but winter navigation on Lake Michigan was not suspended except during the severe cold in the early part of February. . . .

"*Thunderstorms*.—The greatest number of thunderstorms occurs in the South Atlantic and Gulf States and the Mississippi Valley. The number diminishes toward the northward and westward, although there seems to be a second region of maximum frequency along the eastern foothills of the Rocky Mountains in Colorado, Wyoming, and northern New Mexico. West of the Rockies, except possibly in Idaho, the number diminishes to less than 20 per annum. In California, Oregon, and Washington they rarely occur on the immediate coast, but are not infrequent in the interior valleys and mountains back of the coast range. In Arizona they are most frequent in July and August, the rainy season in the mountainous part of that Territory.

"There seem to have been more thunderstorms in 1899 than in the preceding year, although the difference is not very great. The greatest increase in the number of thunderstorms in 1899, as compared with 1898, occurred in the States of Florida, Michigan, Wisconsin, Minnesota, Iowa, and Nebraska. In a number of States, particularly those bordering on the Gulf of Mexico, there were fewer thunderstorms in 1899 than in 1898."

The climate of San Francisco, Cal., A. G. McADIE and G. H. WILLSON (*U. S. Dept. Agr., Weather Bureau Bul. 28, pp. 30, charts 4*).—Data relating especially to temperature and rainfall, accumulated at the San Francisco Station during the last 30 years, are reported in detail.

"The mean annual temperature, as determined from the records of the Weather Bureau for 28 years, is 56.2°. May and November have practically the same temperature. The warmest month is September, 60.9°; the coldest January, 50.1°; the other months have mean temperatures as follows: February, 52°; March, 54°; April, 55°; May, 57°; June, 59°; August, 59°; October, 60°; November, 56°; December, 52°.

"The highest temperature ever recorded in San Francisco was 100° on June 29, 1891, and the lowest 29° on January 15, 1888. Abnormally warm and cold periods last, as a rule, about 3 days. The mean of the 3 consecutive warmest days at San Francisco has never exceeded 76.3°. A period of warm weather during the summer months is, as a rule, brought to a close about the evening of the third day with strong west winds, dense fog, and temperatures ranging from 49 to 54°. The mean of the 3 consecutive coldest days was 40.7°. The greatest daily range of temperature was 43°, on June 29, 1891. . . .

"July and August are practically without rain, while December and January together have nearly 10 in. The annual rainfall is 23 in.

"By comparing the seasonal rainfall with the crop yield it would appear that in years when the rain falls generously in March and April the yield is largest, other things being equal. In other words, it is the time distribution of the rain, more than the intensity or total rainfall, which benefits vegetation. . . .

"The summer fogs of San Francisco result from a chilling of the upper warm air, descending to the ocean surface, and particularly over the cold current close to the shore. There is a great difference of temperature between the valley and the ocean, often 50° within as many miles, and this is probably the prime factor in establishing a marked air movement, shown by the strong indraft through the Gate on summer afternoons."

The meteorology of Ben Nevis in clear and in foggy weather, J. Y. BUCHANAN (*Trans. Roy. Soc. Edinburgh, 39 (1899), pt. 3, No. 31, pp. 48, pls. 8*).—In this paper observations on pressure, temperature, 3809—No. 1—3

rainfall, tension of aqueous vapor, wind, cloud, and sunshine at the summit of Ben Nevis during 13 years. January, 1885, to December, 1897, inclusive, have been grouped in periods of clear weather (24 or more hours during which no fog was recorded), and of foggy weather (3 or more consecutive days during which fog was recorded at every hour). The tabular data show that the maximum rainfall during any one day of the 13-year period was 7.29 in.; the maximum for any one hour 0.85 in. There was a large and continuous excess of atmospheric pressure in clear weather over that in foggy weather, the mean yearly excess being 0.456 in. In foggy weather the vapor tension was that of saturation at the temperature of the air, and the variations were slight. In clear weather the variations were considerable. The mean yearly temperature was 3.57° F. higher in clear than in foggy weather, the maximum monthly excess being greatest in June, when it reached 10.11° . In the first 3 months of the year, however, the temperature was higher in foggy weather than in clear weather, the excess being 2.92° F. in February. The range of mean hourly temperature was much greater in clear than in foggy weather in every month. A nocturnal heating during the winter months was observed both in clear and in foggy weather, though it was more pronounced in the clear weather.

The climate of New York, E. T. TURNER (*Bul. Amer. Geogr. Soc.*, 1900, No. 2).—It is stated in *Science*, n. ser., 11 (1900), No. 285, p. 955, that this article "is largely a reprint of a report upon the same subject by Mr. Turner, originally published in the Fifth Annual Report of the Meteorological Bureau and Weather Service of the State of New York (Albany, 1894, pp. 347-457). Several new charts have, however, been added, including some typical barograph and thermograph curves, and two thunder-storm charts."

Meteorological observations, J. E. OSTRANDER and A. C. MONAHAN (*Massachusetts Hatch Sta. Met. Buls.* 133, 134, 135, pp. 4 each).—Daily and monthly summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January, February, and March, 1900, with notes on the general characteristics of the weather of those months.

Meteorological record (*New York State Sta. Rpt.* 1898, pp. 569-577).—This includes a monthly summary of precipitation at Geneva, N. Y., during 17 years, 1882-1898; and daily and monthly records of the direction of the wind during 1898 and of the temperature during 1898 and during 5 years, 1894-1898.

The weather (*Ontario Bureau Ind. Rpt.* 1898, pp. 1-4).—Monthly summaries of observations at different points in Ontario (with averages for the Province) during the growing season (April to September) of 1897 and 1898, with averages for 1892-1898, on temperature, precipitation, sunshine, etc.

SOILS.

The soluble salts of cultivated soils, F. H. KING and J. A. JEFFERY (*Wisconsin Sta. Rpt.* 1899, pp. 219-243, figs. 3).—In order to study the influence of tillage on the soluble salt content of soils determinations were made of soil moisture and soluble salts in 1 ft.

sections to a depth of 4 ft. on plats of medium clay loam soil having clay subsoil changing to sand at a depth of 4 ft. The soil had been in pasture during 1896 and 1897 and bore a crop of rape in 1898, no fertilizers or manure having been used during this interval. The soil was plowed, rolled, and harrowed on May 23 and was cultivated weekly thereafter until September 15. It was kept fallow and free from weeds.

The methods used in making the determinations are described. For the soluble salts Whitney's electrical apparatus was employed (E. S. R., 9, p. 535). In every case, however, "the amount of dry soil and of moisture in the cell was determined by weighing the cell full before each determination, and then, after measuring the resistance, emptying the contents into the trays, drying the soil, and from the percentage of water calculating the amount of water and of dry soil which occupied the cell when each resistance was measured."

The formula used with the electrolytic soil in these observations was

$$A = 6.06 \frac{W^2}{RS}$$

where A is the per cent of soluble salts in the dry soil expressed as sodium chlorid, W the amount of water in the cell, R is the observed resistance at 60° F., S is the amount of dry soil in the cell, and 6.06 is a constant whose logarithm is 0.782501.

Observations were made at 4 different dates to determine the changes in the soluble salts in the soil with the following results:

The mean change in soluble salts computed as sodium chlorid in fallow ground between May 24 and September 15.

	1st foot.	2d foot.	3d foot.	4th foot.
	<i>Lbs. per acre.</i>	<i>Lbs. per acre.</i>	<i>Lbs. per acre.</i>	<i>Lbs. per acre.</i>
Amount September 15.....	447.5	347.1	200.1	78.8
Amount May 24.....	211.9	240.2	164.7	59.6
Gain	235.6	106.9	35.4	19.2

"The mean gain of soluble salts, and presumably of plant food also, has taken place most rapidly in the surface foot, the increase being more than double that in the second foot, nearly 7 times that in the third, and 12 times that in the fourth foot.

"The total mean gain in soluble salts per acre in the upper 4 ft., as indicated by the method, was 397.1 lbs., and the total amount at the end of the season in the root zone was 1,073.5 lbs. per acre."

Observations on the influence of different depths and frequencies of tillage on soluble salts of the soil indicate "that the largest increase in the amount of soluble salts occurred in the surface foot of the fallow plat not cultivated, the final gain between May 24 and September 15 being 533 lbs. per acre, which is 2.6 times the mean gain which occurred in the surface foot of the cultivated soil." The surface foot of plats cultivated once in 2 weeks gained more than that of plats

cultivated once each week. Apparently the methods employed were not sufficiently delicate to show with certainty whether either the frequency or depth of cultivation made any marked difference in the amount of available plant food.

"The mean change in the soluble salt content in the cultivated fallow plats, as indicated by the Whitney method, between May 24 and September 15, was 361.1 lbs. gain, while the increase on the fallow plat not cultivated was 692.2 lbs. per acre. The mean gain in nitric acid (HNO_3) was 330.56 lbs. per acre on the cultivated plats and 371.39 on the ground not cultivated up to August 22."

Similar observations made May 12 and 13 and August 7 on plats on which crops were growing showed that the soluble salts remained nearly constant in the upper 4 ft. of soil, there being a tendency to decrease on the whole rather than to increase. The average decrease observed was 174.2 lbs. per acre, while on the fallow plats the mean gain during the period of observations was, as stated above, 397.1 lbs.

The value of determinations of soluble salts as an index of evaporation from the soil is discussed at some length.

The electrical resistance by Whitney's method, computed as sodium chlorid, the amount of nominal alkalis, partly and possibly largely sodium carbonate, as indicated by Hilgard's method for detecting black alkali, and the amount of nitric acid were determined August 14 in plats of productive and unproductive humus soils planted to potatoes and treated with sodium and potassium carbonates and wood ashes.

"The method of detecting the nominal alkalis in the soil which has been used consisted in weighing into a small muslin sack 50 gm. of the fresh soil and washing this during 2 minutes with 255 cc. of distilled water poured into the sack in a mortar. By holding the sack closed and on its side and working it with the pestle, turning it from time to time, the soluble salts are quickly taken up by the water. The water is then wrung from the sack and the solution poured into a mug to settle. When clear 25 cc. of the filtered solution is evaporated to dryness and then redissolved and titrated against deci-normal hydrochloric acid. The balance of the soil sample is dried to determine the water content and the percentage obtained used in calculating the alkalinity of the soil. . .

"In [determining nitric acid] a weighed fresh sample [of soil], usually 50 gm., was placed in a small muslin sack in a mortar. Into the sack was poured 250 cc. of distilled water. Holding the sack closed in one hand and the pestle in the other the soil was worked by pestling and turning during 2 minutes, when the sack was removed and drained by wringing and squeezing.

"The turbid solution was transferred to mugs and allowed to stand for from 6 to 12 hours to settle. It was found, however, that long standing was not permissible, especially with humus soils, on account of a tendency to denitrification.

"Corrections were made, in the calculations, for the moisture in the fresh sample used by determining the water content in the balance of the sample. This plan was followed to avoid the danger of increasing the nitrogen content by drying and to avoid changing the solubility of the soil by heating, our object being to get the total soluble salts by the Whitney method and the amount of nitric acid by the phenyl sulphate method of Leffmann and Beam."

The largest amount of nominal alkalis was found in the surface 6 in. of the soil treated with sodium carbonate. In general the amount of

soluble salts was higher in the poorer soil than in the better soil, but the difference was not so great as to make it probable that the unproductiveness was due purely to overconcentration of salts. The sum of the alkalis and nitric acid found by chemical methods usually exceeded the total soluble salts indicated by the electrical method.

Similar observations on a humus soil near Hanover Junction showed that plats of this soil planted to onions and treated with land plaster contained 1,043.3 lbs. of alkali per million of dry soil, while untreated plats contained 1,026.44 lbs.

"Samples taken from a wild marsh, where the wild iris grows, showed 682.03 lbs. per million, but where the grass was much shorter and where from previous experience the largest amount of alkalis would be expected if poor crops were due to its presence, the analysis showed a little less, or 639.6 lbs. per million of dry soil."

Determinations of the amount of nitric acid in fallow plats May 24 and August 22 show that the average amount of nitric acid in the surface 4 ft. of soil at the first date was 111.42 lbs. per acre. At the latter date the nitric acid had increased to 430.11 lbs. One series of these plats was cultivated every week, the other once in 2 weeks, but it does not appear that the cultivation had any notable influence on nitrification.

The total gains per acre in nitric acid under the different treatments were as follows:

Gains of nitric acid in soils from May 24 to August 22.

	Pounds.
Cultivated 2 in. deep once per week	315. 49
Cultivated 2 in. deep once in 2 weeks	307. 44
Cultivated 3 in. deep once per week	321. 80
Cultivated 3 in. deep once in 2 weeks	377. 52
Not cultivated.....	371. 39

"It is clear in regard to the fallow plats under consideration that if the porosity of the soil on the plat not cultivated was such as to give the nitrifying germs all of the air they could use to advantage, then no amount of cultivation would have increased the rate of niter forming. Indeed, it might be true that frequent shallow cultivation in a wet season, especially on a heavy soil, might so much reduce the amount of air which could enter the unstirred soil below the mulch as to act as a positive check, the excess of moisture retained acting to exclude the air and thus retard nitrification or even bring about the reverse process. Then, too, with the soil moisture held to a high point smaller amounts of rain would be able to produce leaching and in this way cause a greater loss of the nitrates formed than would be the case in a less nearly saturated soil. It is not impossible that these conditions may have operated to lessen the nitrate content in the cultivated fallow plats this season."

In the experiments on the influence of early tillage in conserving moisture, reported elsewhere (E. S. R., 11, p. 520), the nitric acid was determined April 30, 18 days after the soil had been plowed. The results show that the plowing sensibly increased the nitrogen in that time. Determinations of nitrates were again attempted on May 16. While the results were unsatisfactory, they indicated that the amount of nitric acid had been greatly reduced in that time, due to rains, the loss being greatest on the soil in the most open condition.

Nitric acid and total soluble salts computed as sodium chlorid were determined in soil mulch and unstirred soil immediately below the mulch on September 22. The results indicate some difference due to the different depths of cultivation (2 and 3 in.), the nitric acid being higher in the mulches formed by cultivating 2 in. deep than in those formed by cultivating 3 in. deep. There appeared, however, to be no such evident relation between cultivation once a week and cultivation once in 2 weeks.

"The loose mulch developed in the cultivation of the several plats was measured by collecting, weighing, sampling, and determining the water content of the samples, and the results showed that about 42 per cent more loose soil was developed on the 3 in. cultivation than on the cultivation 2 in. deep. The amount of nitric acid shown to be in this mulch was a little more than 200 lbs. per acre."

Determinations of nitric acid made April 15 in irrigated and unirrigated soil to a depth of 3 ft. showed, with one exception, "that the ground which had been irrigated and which produced the largest amount of dry matter showed a larger percentage of nitric nitrogen in the soil."

"It should be said in regard to irrigation that only so much water has been applied as it was thought the crop could use to advantage, and no water had been applied to the irrigated ground since the preceding August; further, the plat has been in corn continuously without fertilizers, since 1894."

The character and treatment of swamp or humus soil, F. H. KING and J. A. JEFFERY (*Wisconsin Sta. Bul. 80, pp. 39, figs. 14*).—The extent and character of swamp or humus soils in Wisconsin are described, and experiments on their management, in continuation of similar work in previous years (*E. S. R.*, 10, p. 728), are reported. Accounts are given of plat and of pot experiments on soil of productive and unproductive areas of a reclaimed marsh with coarse, rotted, and liquid manure; cut and ground straw, ground oats, corn, and rye (with and without addition of carbonate of potash); green manure (oats); gypsum, sand, and clay; magnesium carbonate and sulphate; wood ashes; muriate, sulphate, nitrate, and carbonate of potash; and nitrate of soda. The amount of soluble salts present (nitrates and alkalis) and the effects of leaching, drainage, and adding drainage water from humus soils were also studied. The crop grown was corn.

Notwithstanding the presence of large amounts of nitrates in the soil on May 4, barnyard manure produced a marked increase in the crop, thus indicating that its beneficial effect was not due to increased nitrification.

Applications of sand and clay produced no benefit. Land plaster reduced the amount of alkali present (see p. 31) but did not increase the yield.

In the pot experiments with magnesium salts the carbonate was used in saturated solution at the rate of 541.1 lbs. per acre, the sulphate at

rates of 3,082 and 3,727 lbs., corn being the crop grown. The carbonate decreased the yield on both the poorer and the better soil; the sulphate reduced the yield on the better soil. These experiments were repeated on the same pots with increased applications of the magnesium salts. Similar but more decided results were obtained. Both salts reduced the yield, but the action of the carbonate was more marked than that of the sulphate.

The use of water from the tile drains under humus soil for watering corn grown in pots was not attended with any injurious effect as compared with rain water.

Leaching the soil very materially decreased the yield. Magnesium carbonate was very injurious on leached soils, while the sulphate appeared to be beneficial. There was no indication that the reduced yield was due to the loss of nitrogen by leaching, which was quite large. The plowing under of green oats increased the yield on the poor soil but decreased it on the good soil.

Other general conclusions from this work are thus summarized in the bulletin:

“(1) There are in Wisconsin alone in the neighborhood of 4,000 square miles of humus soils, most of which may readily be drained and put in condition for tillage.

“(2) So far as the elements of plant food are concerned they contain a higher percentage than most of the best upland soils.

“(3) The soil when drained is easy to work and maintains an excellent tilth.

“(4) But when reclaimed they are often found relatively unproductive, especially after 2 or 3 years.

“(5) Their productiveness frequently varies to a marked degree in different seasons and without an evident cause for it.

“(6) Coarse farmyard manure, in almost all cases, greatly improves even the best of these lands, enabling them to give large yields.

“(7) Liquid farmyard manure has not been found to have an appreciable influence on the yield.

“(8) Potassium carbonate, sulphate and nitrate and wood ashes have been found to greatly improve these soils for corn. Kainit improves the yield, but to a less degree. [The beneficial effect of the potash salt is apparently exerted near the surface of the soil.]

“(9) Potassium chlorid in one-half the quantity of other salts killed the corn.

“(10) Land plaster, lime, marl, phosphates, bone meal, and Thomas slag have been tried with little benefit.

“(11) Coarse litter, like straw, plowed in is often very helpful.

“(12) A good dressing of manure may materially increase the yield for 4 consecutive years.

“(13) Heavy crops of oat hay can often be grown upon the lands, but the plants are liable to lodge and not fill well if left to mature.

“(14) It is difficult to get a good stand of clover, and winterkilling is very common.

“(15) Timothy and redtop appear to do best among the grasses, but it is often very difficult to get a stand of these if the field has been cultivated several years.

“(16) Almost any crop may be grown upon these soils, if they are manured, and very heavy crops of corn.

“(17) As pastures these lands only give a moderate amount of feed.

"(18) When undrained and kept in the native wild grass, and cut continuously, these lands in some known cases greatly decrease in productiveness, so much so as to hardly pay for cutting.

"(19) In sowing to grain and seeding after corn, which has been kept clean, it will generally be best not to plow, on account of the naturally loose character of the soil. If plowing must be done and the ground is dry enough to do so, it will be best to roll to increase the firmness.

"(20) When clover has winterkilled, leaving the timothy standing, the ground may be seeded to clover very early in the spring by sowing on the surface and harrowing lightly."

Percolation and evaporation from long columns of soil, F. H. KING (*Wisconsin Sta. Rpt. 1899, pp. 214-218*).—In continuation of previous studies (E. S. R., 10, p. 727), the author made observations (1) on the rate of percolation from saturated sandy loam and clay loam soil in brass cylinders 7 ft. long and 3 in. in diameter, and (2) on loss of water by evaporation from similar soils, mulched and not mulched, in galvanized-iron cylinders 10 ft. long, having a cross section of 0.04611 sq. ft.

In the first case the cylinder was made in sections 6 in. long, which could be screwed together, forming water-tight joints. The top of the cylinder was provided with a closely fitting screw cap and the bottom with devices for collecting, maintaining at a uniform level, and removing the percolating water, with the minimum of evaporation.

"The apparatus was filled with soil containing a good working amount of moisture, and was introduced in small, uniform quantities at a time, tamping each quantity added with the same number of strokes. When filled, the soil was completely saturated with water by filling from the bottom under pressure until the water overflowed at the top.

"The rate of percolation and the amount of it was obtained by weighing at 7 a. m. each morning after the first rapid discharge had taken place, and the table below gives the distribution of moisture by 6-in. sections, as found 60 days after percolation was started."

Distribution of moisture in soil at different distances above standing water after 60 days of percolation without evaporation.

Above standing water.	Sandy loam.	Clay loam.
	<i>Per cent.</i>	<i>Per cent.</i>
84 in. to 78 in.....	16.16	31.16
78 in. to 72 in.....	16.08	30.70
72 in. to 66 in.....	16.55	31.05
66 in. to 60 in.....	16.97	31.11
60 in. to 54 in.....	17.59	31.21
54 in. to 48 in.....	17.99	31.94
48 in. to 42 in.....	18.70	31.99
42 in. to 36 in.....	19.44	32.18
36 in. to 30 in.....	20.90	32.45
30 in. to 24 in.....	21.71	33.31
24 in. to 18 in.....	21.46	34.40
18 in. to 12 in.....	22.17	35.54
12 in. to 6 in.....	22.68	35.97
6 in. to 0 in.....	27.69	37.16

There were several days during the course of the experiment in which there was no percolation. These were usually days of lower temperature and of higher barometer.

"The sandy loam contained in the 7 ft. of soil when completely filled with water, 29.61 in.; it lost by percolation 6.339 in. and retained 23.271 in. The clay soil began the trial with 37.17 in.; it lost during the 60 days 3.147 in. and still retained 34.023 in. in the 7 ft. The sandy loam could retain in its surface foot after 60 days, percolation without evaporation 2.83 in. and the clay soil 4.565 in. of water."

For the observations on evaporation 2 sets of cylinders of 2 each were filled with sandy loam and clay soil in the manner described above. "The sandy loam contained, when put in, 18.88 per cent of water and the clay soil 32.63 per cent. After the 4 tubes had been filled the soil was removed from one of each set to a depth of 3 in. and as much returned as a loose mulch as was required to again fill the tubes level full."

The tubes were placed in a ventilating shaft and a continuous draft of air was maintained across their surfaces from November 26, 1898, to October 6, 1899. At the end of that period the tubes were sawed off in 6 in. sections and the distribution of moisture in the columns determined with the following results:

Loss of water by surface evaporation from columns of soil 10 feet long, mulched and not mulched.

	Sandy loam.		Clay soil.	
	Mulched 3 in.	Not mulched.	Mulched 3 in.	Not mulched.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Surface 6 in.	8.83	7.41	17.66	7.79
6 in. to 12 in.	12.97	14.48	24.59	18.30
12 in. to 18 in.	14.59	14.70	26.58	21.46
18 in. to 24 in.	15.25	14.96	26.95	26.26
24 in. to 30 in.	15.55	15.53	27.45	26.89
30 in. to 36 in.	15.89	16.17	27.92	27.16
36 in. to 42 in.	16.22	16.33	27.94	27.61
42 in. to 48 in.	16.29	16.33	28.24	27.64

72 in. to 78 in.	17.56	17.79	29.24	28.93
78 in. to 84 in.	17.78	17.88	29.28	28.31
84 in. to 90 in.	17.94	17.85	29.35	28.32
90 in. to 96 in.	17.96	17.67	29.79	28.80
96 in. to 102 in.	18.25	18.05	30.32	29.14
102 in. to 108 in.	18.67	18.09	31.15	29.16
108 in. to 114 in.	18.53	18.63	30.47	29.33
114 in. to 120 in.	19.21	19.95	31.25	29.46

"It is clear from this table that there has been an upward movement of water and loss through the surface even from the bottom layers of soil in the case of the medium clay, and probably also from the sandy loam. . . .

"It is certain that a drying of these soils has taken place through a depth of 10 ft., and hence that moisture 10 ft. below the surface of the ground may become available for vegetation purposes at or near the surface."

It is not certain, however, that this upward movement of water is due entirely to capillarity. It is suggested that "it may be found that internal evaporation takes place in soils allowing water to pass up through the soil pores of drier soils by gaseous diffusion and condense on the colder soil grains higher up. If this is true, then these observations do not prove that there is danger of capillary rise of

alkalis from depths as great as 10 ft." It is the author's belief, however, "that the changes observed and recorded for the 10 ft. columns were largely if not wholly due to capillarity."

The utilization by plants of the potash dissolved in soil water, T. SCHLOESING (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), pp. 422-424; *obs. in Chem. Centbl.*, 1900, I, No. 12, p. 686).—The studies on soil-soluble potash reported in this article were of the same character as previous investigations on soil-soluble phosphoric acid (E. S. R., 11, p. 821). It is shown that the soil potash is dissolved only in very small amounts by the water of the soil, even when present in large amounts. It is stated that in a soil containing from 3,000 to 4,000 kg. of potash per hectare there will be only from 1 to 5 kg. of potash soluble in water at any given time. However, this potash gradually becomes available as required by the plant, and the author's experiments with corn showed that this plant was able during its growing period to obtain a sufficient amount of potash for a very large growth from a soil which showed only a very small amount of potash at any given time.

Catalogue of the first four thousand samples in the soil collection of the Division of Soils, M. WHITNEY (*U. S. Dept. Agr., Division of Soils Bul.* 16, pp. 145).—The bulletin explains the agencies through which the collection was obtained, describes the typical areas and formations represented, and gives reference to mechanical or chemical analysis. The collection includes samples from all of the States and Territories of the United States, except Maine and Wyoming, and from Bermuda, China, Cuba, England, Germany, Mexico, Russia, and Sumatra. The main object of the catalogue is stated to be to call attention to the large number of samples at present in the possession of the Division of Soils with a view to extending the collection by cooperation or exchange with individuals, organizations, and institutions interested in the subject.

"In order to call attention still more forcibly to the importance and value of the soil collection, and to extend this educational work, collections of representative soils are being put up in small glass bottles, arranged in boxes with 22 compartments in each. These sets are to be distributed to the agricultural colleges and experiment stations, with explanatory text regarding the origin, the chemical and physical peculiarities, and the agricultural value of the samples, together with a statement of the physical and chemical analysis of each."

Treatment of swamp or humus soil, F. H. KING and J. A. JEFFERY (*Wisconsin Sta. Rpt.* 1899, pp. 244, 245, fig. 1).—This is a brief summary of results of investigation on this subject which are reported in detail elsewhere (p. 32).

A method of ascertaining the fertility of different parts of an experimental field by the use of control plats, J. P. D'ALBUQUERQUE (*West Indian Bul.*, 1 (1900), No. 2, pp. 187-193).

Readings of soil thermometers (*New York State Sta. Rpt.* 1898, pp. 578-584).—This is a tabular record of tridaily readings of soil thermometers during 1898 at depths of 1 to 18 in.

New problems in soil inoculation, J. STOKLASA (*Deut. Landw. Presse*, 27 (1900), No. 17, pp. 189-191; *abs. in Chem. Ztg.*, 24 (1900), No. 24, *Repert.*, p. 86).—The author found that the Alinit bacteria assimilated the free nitrogen of the air, but only in the presence of an excess of carbohydrates and with the assistance of a bacillus which occurs particularly in humus soils. The latter organism was isolated and studied.

FERTILIZERS.

The utilization of stable waste, W. H. BIRCHMORE (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 2, pp. 118-121).—The author concludes from his observations and experiments that the fertilizing value of stable waste depends largely if not entirely upon the activity of the micro-organisms in the manure or in the soil to which it is applied. It was found that "an average sample of stable waste lost 40 per cent of its contained nitrogen in the first 2 hours after it was swept into the pit. Of this loss full three-quarters was in the fourth half hour." The author succeeded in preparing cultures which on being introduced into the manure heap set up an acid fermentation which prevented the loss of ammonia. The method of procedure was as follows:

"The stable waste, solid and fluid, as it accumulated, was collected in a closed and acidulated receptacle. Into this was turned a certain amount of a culture,¹ which in a very short time reduced the whole to a mud containing nitrates, ammoniacal salts, and phosphates, together with a relatively pure culture of certain organisms.

"This material, which has a peculiar sour smell, may be mixed with ashes and allowed to ferment with free access of air, a pure culture or a quasi-pure culture of other organisms being added, or in place of this some well-advanced material from a portion of waste already well 'worked.'

"If a relatively pure culture be used, the entire mass is reduced to a black loam within a very short time, and this loam I have used for cultivating plants with great success. Plants grown in it show reproductive bodies of exaggerated size as compared with the size of the plants by which they are produced."

The author isolated from soils different groups of organisms which it is claimed are essential, one for the growth of cereals, another for potatoes, a third for grass. Unless the particular organisms favoring the growth of the crop under cultivation are present in the soil the application of stable waste will not be effective in increasing the yield.

Investigations on the influence of nitric nitrogen and ammoniacal nitrogen on the growth of maize, P. MAZÉ (*Ann. Inst. Pasteur*, 14 (1900), No. 1, pp. 26-45; *abs. in Jour. Agr. Prat.*, 1900, I, No. 11, pp. 382-388; *Chem. Centbl.*, 1900, I, No. 12, p. 687).—In these investigations it was found that corn assimilated these 2 forms of nitrogen with equal facility, if furnished in suitable proportions. The best results were obtained with a 0.2 per cent solution of nitrate and a 0.05 per cent solution of ammonium sulphate. A 0.2 per cent solution of ammonium sulphate killed the plants. The injurious effect of ammo-

¹The nature and method of preparation of this culture is not explained.

nium sulphate sometimes observed in practice is believed by the author to be due to the use of too large amounts of the salt. Damp weather favors the beneficial effect of ammonium salts by diluting the soil solutions, and dry weather increases its injurious effects by concentrating them. The general conclusion is drawn that ammonia is just as effective as a fertilizer as nitric nitrogen, but that it must be used with caution.

Experiments on the preservation of barnyard manure, M. HOFFMANN (*Deut. Landw. Presse*, 27 (1900), No. 29, pp. 354, 355).—An account is given of tests of Sulfarin, a commercial preparation in which the preservative agent is sulphuric acid (15 to 18 per cent).

The question of the preservation of barnyard manure, J. KOENIG (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 7, pp. 273-276; 8, pp. 290-295).—This is a popular discussion of this subject, based upon investigations by the author and others, in which it is claimed that the best results will be obtained in the management of manure by protection from access of air, rain, and sun, and by thorough rotting.

On the construction of practical manure pits, H. STRUWE (*Deut. Landw. Presse*, 27 (1900), No. 37, pp. 454, 455, figs. 10).—Plans and instructions for the construction of different kinds of pits are given.

Practical results of experiments in sewage treatment, T. W. H. GARSTANG (*Public Health*, 12 (1900), No. 8, pp. 612-622).

Report on the Government guano islands for the year 1899, C. H. JACKSON (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 8, pp. 485-489).—Statistics of collection and shipments of guano from the Colonial and Ichaboe Islands are given, and the price, extent of use, and possible future output are discussed. In 1899 the Colonial Islands produced 2,801 tons of guano, the Ichaboe Islands 2,211 tons.

Commercial fertilizer calendar for the year 1900, M. ULLMANN, editor (*Notiz-Kalender über die Anwendung künstlicher Düngemittel für das Jahr 1900*. Hamburg: J. H. Koch & Co., 1900, pp. 48).

The composition and use of fertilizers, L. L. VAN SLYKE (*Pennsylvania Dept. Agr. Bul.* 55, pp. 132).—A revised edition of Bulletin 94, new series, of the New York State Station (E. S. R., 7, p. 853).

Analysis of commercial fertilizers sold in Maryland, H. B. McDONNELL ET AL. (*Maryland Agr. Col. Quart.*, 1900, No. 7, pp. 67).—This bulletin discusses the composition of plants, the nature and source of various fertilizing materials, the value of plant and soil analysis for determining the fertilizer requirements of soils, the market price and valuation of fertilizers, and home mixing of fertilizers; and gives tables showing the census statistics (1860-1890) of fertilizer production in the United States, the average composition of the more important fertilizing materials and of farm manures, the fertilizing constituents of feeding stuffs and farm products, the amount of plant food remaining in different kinds of soil 6 years after the application of various fertilizers, the amount of fertilizing materials contained in different crops grown on 1 acre, and analyses and valuations of 328 samples of fertilizing materials examined at the college from August, 1899, to January, 1900, inclusive. There are also given the text of the State fertilizer law and a supplementary list of fertilizers licensed for sale in Maryland for the year ended February 1, 1900.

Analyses of commercial fertilizers, W. F. HAND ET AL. (*Mississippi Sta. Bul.* 61, pp. 15).—This bulletin reports analyses and valuations of 48 samples of fertilizers collected during December, 1899, with some incidental explanation.

Fertilizer analyses, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 21 (1900), No. 4, pp. 22).—This bulletin gives notes on valuation, freight rates from the seaboard to interior points of North Carolina, a list of fertilizers registered during

1900 (with guaranteed composition), and analyses and valuations of 181 samples of fertilizers examined by State chemist during the spring of 1900.

Analyses of commercial fertilizers, J. HAMILTON and W. FREAR (*Pennsylvania Dept. Agr. Bul. 54, pp. 163*).—This includes the text of the State fertilizer law, notes on valuations, a list of manufacturers securing licenses for the sale of fertilizers in Pennsylvania in 1899, and tabulated analyses and valuations of 716 samples of fertilizers examined during the year 1899.

Analyses of commercial fertilizers, H. J. WHEELER and B. L. HARTWELL (*Rhode Island Sta. Bul. 60, pp. 39-48*).—This is the third of the bulletins of this station dealing with the inspection of fertilizers in Rhode Island during 1899. It includes analyses and valuations of 47 samples of mixed fertilizers and 9 samples of wood ashes. The comparative quality of the complete fertilizers sold in the State from 1891 to 1896 and in 1899 was as follows:

Comparative quality of fertilizers sold in Rhode Island.

	1891.	1892.	1893.	1894.	1895.	1896.	1899.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Equal to or above the guaranty.....	71.1	80.7	75.7	80.9	89.0	90.7	84.9
Less than 0.3 per cent below the guaranty..	10.6	9.0	13.8	8.0	5.0	4.8	6.9
More than 0.3 per cent below the guaranty..	18.3	10.3	10.5	11.1	6.0	4.5	8.4

Report of fertilizer department, J. P. SMITH (*South Carolina Sta. Rpt. 1899, pp. 32-34*).—A brief account is given of the work of sampling and inspecting fertilizers during the year ended December 31, 1899. According to the reports of the official inspectors, the amount of fertilizers sold in the State during 1899 was 241,299 tons as compared with 257,393 tons sold in 1898. Analyses of the 336 samples of fertilizers examined during the year have been published in bulletins of the station (E. S. R., 11, pp. 438, 831).

Report of chemist, M. B. HARDIN (*South Carolina Sta. Rpt. 1899, pp. 9-16*).—This is a brief statement of the work of this department of the station during the year ended November 30, 1899. It includes notes on farmers' institutes, fertilizer inspection, examination of water, and miscellaneous analytical work.

"Of the 336 samples [of fertilizers] analyzed this year only 6 were deficient under the law, which requires that the commercial value based upon analysis shall not fall 3 per cent below the commercial value based upon guaranty. Besides these 6 deficiencies, however, there were 56 samples, including 1 cotton-seed meal, which fell below guaranty in one or more constituents."

Analyses of licensed commercial fertilizers, 1899, F. W. WOLL and A. VIVIAN (*Wisconsin Sta. Rpt. 1899, pp. 263-266, 316, 317*).—A brief account of fertilizer inspection in Wisconsin during 1899, analyses of 5 fertilizers being reported. The text of the fertilizer law is given.

Analyses of commercial fertilizers obtainable in New South Wales, F. H. GURNEY and T. H. LABY (*Agr. Gaz. New South Wales, 11 (1900), No. 4, pp. 290-294*).—This article discusses the valuations of fertilizers in New South Wales and gives analyses and valuations of 110 samples of fertilizing materials, including various mixed fertilizers, and deposit from wool-scouring tanks, wool waste, "skutch" from limed pelts, decomposed hair and lime, tanyard refuse, sheep manure, bat guano, filter-press muck from cane mills, megass, megass ash, bloodwood ash, ironbark, blackbutt ash, red gum ash, spotted gum ash, boxwood ash, seawood ash, ash of kerosene shale, cave deposit, gypsum, flue deposit from furnaces, night soil, fowl manure, ash of vine cuttings, and seaweed.

Recent researches on nitrification, R. WARINGTON (*Chem. News, 81 (1900), No. 2105, p. 151*).—This is an abstract of a lecture reviewing recent work on this subject, especially that of Winogradsky and Oméliansky.

FIELD CROPS.

The influence of the right amount and right distribution of water in crop production, F. H. KING (*Wisconsin Sta. Rpt. 1899, pp. 206-213, figs. 3*).—This is a continuation of work already reported (E. S. R., 11, p. 537).—An introductory statement is made of the rainfall at the station during the growing season of 1899. The season was not as favorable for crop production as the preceding one as regards distribution of rainfall, although in general excellent results were obtained.

The clover of the experimental plats having been winterkilled, reseeding became necessary. Oats were used as the first crop and clover as the second. The total yield per acre for the 2 crops is tabulated, and the results obtained are compared with those of the 3 preceding years.

Corn was thickly planted for the sixth successive year on the same plat with irrigation, but without application of fertilizers, the aim being to exhaust the soil by cropping as rapidly as possible. The yields for the years 1894-1899, inclusive, are tabulated.

"The yield on the unirrigated ground is the smallest of any but the very dry year of 1895, and that on the irrigated ground is on the average the smallest of any year and only barely equal to that not watered. The corn was very yellow compared with that on other plats and evidently starved, although in the spring the soil showed more nitric acid than was found [in the plat referred to in the next paragraph], and the physical condition of the soil is if anything better than it was in 1894. It appears clear that the feeding capacity of the soil has very much decreased, and yet by standard methods of chemical analysis of soil for available plant food we started in 1894 with enough for heavy crops for more than half a century."

Dent corn was grown in alternate plats, irrigated and unirrigated. The irrigated plats were watered twice. They yielded 10,990 lbs. of dry matter per acre, while the unirrigated plats yielded but 7,985 lbs., showing a difference of 3,005 lbs. or 37 per cent in favor of irrigation.

In the work with potatoes, 4 methods of culture were used: Ridge culture with irrigation, ridge culture without irrigation, ridge culture with straw mulch between the rows, and level culture without irrigation. With Salzer Harvest King, irrigation produced 411.3 bu. per acre, mulching without irrigation produced 343.3 bu., and ordinary ridge culture, 346.7 bu.

"Watering the potatoes twice increased the yield per acre 61.1 bu. of merchantable tubers over the not watered and 59.4 bu. over those mulched with straw. In this case it is clear that the potatoes needed more water than the rainfall of the season, but that the straw mulch did not materially increase the yield over that of the unirrigated subplats."

Determinations of the amount of moisture in the soil of each plat made before the first irrigation showed little difference between the plats in this respect. Similar determinations made 3 days after the last irrigation gave results as follows:

Moisture in soil of potato plats.

	Irrigated.		Unirrigated.		Mulched.	
	Moisture.	Soluble salts per acre.	Moisture.	Soluble salts per acre.	Moisture.	Soluble salts per acre.
	<i>Per cent.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Pounds.</i>
First foot.....	17.30	34.37	10.51	39.69	10.17	35.28
Second foot.....	13.80	49.33	12.38	52.33	12.13	41.12
Third foot.....	14.29	25.81	11.98	29.01	14.68	32.34
Fourth foot.....	13.42	18.03	13.15	19.23	13.07	24.42

"On this date the irrigated soil was markedly more moist than the other 2, but there was not much difference between the unirrigated and mulched soils. It will be seen that the irrigated soils contain the least amount of soluble salts and the mulched most, except in the bottom foot."

Comparisons were made of hill culture with irrigation with hill and level culture without irrigation. As between hill and level culture without irrigation, there was relatively little difference in the yield, the latter giving 9.1 bu. of large tubers per acre more than the former, but more of the potatoes being greened in level culture. In the case of the irrigated potatoes there was an increased yield of 114 bu. of large tubers per acre over the hilled potatoes not irrigated and 108 bu. per acre over those receiving level culture without irrigation.

Seven days after the last irrigation determinations were again made of the amount of moisture in the soil of each plat, this time of the amount in and between the rows respectively. The irrigated plat contained about 6 per cent more water in the surface foot of soil under the hills and 8 per cent more between the rows. The second foot of soil contained about 2 per cent more water than the unirrigated plats. With this increase in amount of soil water is associated an increased yield of about 100 bu. of merchantable potatoes to the acre. "This relation makes it very clear that the right amount of water at the right time is a very important factor in determining the yield. The amount of water which was added to the soil this year to secure this increase in yield was only about 2 acre-inches, divided between 2 irrigations."

Continued effects of fertilizing the soil, W. C. LATTA (*Indiana Sta. Rpt. 1899, pp. 46-50*).—Corn has been grown continuously since 1880 on plats fertilized with either horse manure, gas lime, or ammoniated phosphate to study the residual effects of these manures. The yields of grain and stover on the different plats are given for 10 years for the gas lime and phosphate plats, and for 16 years for the horse-manure plats.

The results show the effects of the lime and ammoniated phosphate on grain yield to be slight and transient. The aggregate increase of corn due to the residual effects of the horse manure has amounted to 131.8 bu. of grain and 6,242 lbs. of stover, estimated to be worth \$55.14.

The average increase of grain in 1898 attributed to the original application of horse manure was 3.17 bu. per acre.

Variety tests of grains, R. A. MOORE (*Wisconsin Sta. Rpt. 1899*, pp. 246-248).—Tests were made of several varieties of oats and barley and one variety each of Russian spelt and Russian millet. A part of the oats and barley were from Canada. All others were imported from Russia by this Department. Wisconsin Mandscheuri barley was compared with the same variety as grown in Canada, to determine whether the seed had lost any of its vitality since being grown in Wisconsin, and also to compare it with some of the newer varieties. The results of this and some other parts of the test were as follows:

“The test shows that the Mandscheuri barley is reliable seed and is especially adapted to our soil and climate.

“The Oderbrucker barley, which, like the Mandscheuri, is a six-rowed barley, gave the largest yield per acre, but was somewhat lighter in weight per measured bushel. These two varieties grew more vigorous and the straw was brighter and stronger than in other varieties tested.

“Of the oats tested, the Siberian and Daubeney gave the best yield per acre of grain, and the Russian No. 2800 the best yield of straw. The Daubeney oats ripened earlier and more evenly than the other varieties, and while the yield of straw was less, it was of an extra fine quality.

“The Russian spelt did not thrive well, and did not produce a good crop of either grain or straw. It does not seem to be well adapted to our conditions, as the warm weather in summer materially affects it.”

The growth of the millet was rapid, and a large amount of hay could have been secured if it had been cut at the proper time. The object of the test, however, was to secure seed. Russian vetches were found to be a promising crop, growing luxuriantly and producing a large amount of fine green forage.

Machine and hand-threshed cereals for seed, H. C. SCHELLENBERG (*Landw. Jahrb. Schweiz.*, 13 (1899), pp. 152-168).—The author's experiments along this line with rye, wheat, spelt, and barley show that the losses for seed purposes due to threshing by machinery were $\frac{3}{10}$ with rye, $\frac{1}{4}$ with wheat, and $\frac{1}{8}$ with barley of the total grain yield. With rye and wheat this was 3 times as great a loss as resulted from the use of the flail, and with barley twice as great. These losses were considerably increased in each case when the seed was treated with a solution of copper sulphate before planting. In general the larger seeds were the ones most injured by threshing. With spelt, only one-fourth of the machine-threshed grain was available for seed purposes.

The nitrogen fertilization of barley for brewing, T. REMY (*Bl. Gersten- Hopfen- u. Kartoffelbau*, 1 (1899), No. 1, pp. 9-36).—Pot experiments in fertilizing barley with different forms and amounts of nitrogen are reported. The moisture content of the pots was varied in some instances. From the results obtained it is shown that nitrate of soda and sulphate of ammonia are more completely used up by the

barley crop than more slowly acting organic forms of nitrogen, as guano and poudrette, since the taking up of nitrogen by this crop is largely confined to the earlier stages of growth. The use of the former compounds of nitrogen, especially nitrate of soda, tends toward an increase of the nitrogen content of the grain, an undesirable feature in barley intended for brewing purposes. When nitrate of soda is used instead of guano, it should be applied in smaller amounts. Nitrate of soda was found especially valuable, as compared with other nitrogen fertilizers, in dry soils. As to the time of application of fertilizers, the author believes that nitrate of soda should be given in 2 applications and not later than the beginning of the stooling of the barley. Sulphate of ammonia and all other forms of organic nitrogen should be applied shortly before the seeding of the barley.

Report on culture experiments with barley at the Berlin Experimental Institute for Brewers, VON ECKENBRECHER (*Bl. Gersten-Hopfen- u. Kartoffelbau*, 1 (1899), No. 5, pp. 133-149).—The details of cooperative field experiments in fertilizing barley with different forms of nitrogen are reported. The data given show the fertilizers applied, yield of grain and straw, weight of 1,000 grains, protein content of the grain, and the comparative value of the grain grown with the different fertilizers. The best barley as regards quality was grown without any nitrogenous fertilizer, and the poorest with guano. The yields of grain and straw and weight of the grain averaged highest on the plats receiving nitrate of soda. The protein content of the grain did not seem to be materially affected by the different fertilizers.

The influence of heredity upon vigor in the potato, E. S. GOFF (*Wisconsin Sta. Rpt. 1899*, pp. 304-308, fig. 1).—A report is made on experiments begun by the author in the spring of 1884 while he was connected with the New York State Station,¹ in the selection of seed potatoes for prolificacy. Comparisons were made year after year of the prolificacy of tubers selected from the most productive and least productive hills. The method of preparing the tubers for planting was to cut the larger tubers to single eyes just before planting in order to eliminate to a large degree the inequality of size in the two lots of tubers. In 1898 the method was somewhat modified in order to further eliminate the inequality that arises from the fact that the tubers from the most productive hill almost always average larger than those from the least productive hill.

The total yield of the most productive hill of Old Long Mercer for 2 years was $63\frac{1}{8}$ oz.; that of the least productive hill, $41\frac{3}{16}$ oz. Similarly, the total yield of the most productive hill of Snowflake for 2 years was $332\frac{1}{2}$ oz., and the yield of the least productive hill for the same time $100\frac{1}{4}$ oz.

¹ New York State Sta. Rpt. 1887, p. 85.

"Adding the total yields of the most productive hill of the varieties together, and subtracting from this sum the same total for the least productive hill, it appears that the actual excess in yield of the seed from the most productive hills was a trifle over 180 per cent. It is difficult to explain this difference in yield on any other hypothesis than the difference in the inherent vigor of the samples of seed planted. It must be remembered that the weight of the seed planted was the same, that the conditions of growth were the same, and that the method of selection was rather against the most productive hills, because while the largest tubers from the least productive hills were used for seed, the majority of the largest tubers from the most productive hills were rejected.

"This experiment has not tended to increase the yield of the varieties used, because the most productive hills were continually hampered by having the seed tubers cut up fine to keep them comparable to the least productive hills. It demonstrates the increased vigor of the most productive hills and nothing more.

"It is believed that these experiments, reaching as they do through 14 years, are sufficient to demonstrate the principle that vigor in the potato plant, as in other plants, may be maintained and increased by selection. The potato grower may doubtless prevent the failure of his varieties by the method of seed selection indicated in this article. Where the digging machine is employed, the best way to carry out the plan would be to grow a plat of potatoes each year on the best soil, to be used expressly for seed selection, and to dig this plat by hand. The selected tubers from this plat could be used the next season to produce the seed for the main crop the following year. This is substantially the method practiced by seed growers in maintaining the vigor and purity of their seeds."

Tests of the sugar beet in Pennsylvania, H. P. ARMSBY and E. H. HESS (*Pennsylvania Sta. Bul.* 47, pp. 8).—A continuation of work with sugar beets previously reported (*E. S. R.*, 10, p. 40). Eleven varieties were tested. Tabulated data as to average size of beets, sugar content, and percentage of purity are given for beets grown in 33 counties, and these data are summarized for the more important sugar-beet districts of the State. A study was made of the best time of harvesting. The average weight of the beets grown in the entire State was 1.33 lbs.; average sugar content, 12.66 per cent; and average percentage purity, 81.8. About the last of October or first of November is considered the most suitable time for harvesting sugar beets in Pennsylvania. Original Kleinwanzlebener and Troensegaard Elite were the 2 best varieties grown.

Test of corn-cultural implements, W. C. LATTA (*Indiana Sta. Rpt.* 1899, pp. 51-53).—The relative value of a number of different makes of cultivators for corn have been tested at the station continuously for 11 seasons. The results thus far obtained, in the opinion of the author, seem to justify the following conclusions: "(1) The kind of implement is not so important as thoroughness and carefulness in using the same. (2) In well-drained soils, deeply broken and well filled with humus, deep culture of the corn crop does not seem necessary at any stage of its growth."

Report on experiments in 1899, J. R. DUNSTAN (*Agr. Dept. Univ. Col., Nottingham [and] Midland Dairy Inst.*, 1899, pp. 35).—Report on cooperative manure and variety experiments with potatoes, barley, and grass; on spraying charlock; and on rotation, manure, and cropping experiments.

New contribution to the question of the influence of the water content of the soil on the development of the plant, C. VON SEELHORST (*Jour. Landw.*, 48 (1900), No. 2, pp. 165-177, pls. 2).—A study of the influence on the form and composition of oats and spring wheat of varying amounts of water in the soil and of increasing and decreasing the water content of the soil at different stages of growth.

Action of sulphuric acid employed in watering clover and sugar beets, A. DAMSEAUX (*Bul. Agr. [Brussels]*, 15 (1899), No. 7, pp. 619, 620).—In these experiments the plants were watered with a solution containing 24 gm. of sulphuric acid to each liter of water. The results were positive. The production of stems and leaves was diminished and the constitution of the plants modified. In the case of the clover the yield was much reduced by the use of the acid. With sugar beets the total yield and the percentage of sugar were both reduced. The quotient of purity was slightly raised and the percentage of sulphuric acid in the ash almost doubled.

Russian cereals adapted for cultivation in the United States, M. A. CARLETON (*U. S. Dept. Agr., Division of Botany Bul. 23*, pp. 42, pls. 2, figs. 2).—A general discussion is given of the characteristics of Russian and American grain soils, climatic conditions of the grain belts of the two countries, etc., with notes showing the cultural methods followed in Russia, and other data on each of 7 varieties of wheat, 3 of oats, 2 of barley, 2 of emmer, 6 of millet, and 1 each of Indian corn, buckwheat, Tambou flat pea, and *Polygonum weyrichii*, recently secured from Russia for trial in this country, and similar data on a number of other varieties of wheat and oats now being introduced. Descriptive notes as to Russian methods of harvesting, threshing, cleaning, and milling wheat are included in the bulletin, as is also a list of Russian cereals already grown in this country, notes on the preparation of cereal foods in Russia, and suggestions regarding the requirements of a proper test of new cereals.

Cotton, H. LECOMTE (*Le coton. Paris: J. B. Baillière & Sons, 1900*, pp. 496, figs. 37).

The manuring of cotton, G. P. FOADEN (*Jour. Khediv. Agr. Soc. and School of Agr.*, 2 (1900), No. 2, pp. 87-91).—The use of barnyard manure increased the yield of cotton, but decreased the quality of the staple. Medium applications of poudrette gave profitable returns, yielded a higher proportion of fiber in ginning, and produced superior cotton. Experiments in the use of guano did not give conclusive results.

Culture experiments with German, English, and French fodder beets (*Landw. Wehnschr. Sachsen*, 2 (1900), No. 18, pp. 159, 160).—Tests of 10 German, 6 French, and 4 English varieties of fodder beets are reported. Yellow Eckendorfer, Yellow Tannenkrüger, and Red Eckendorfer of the German varieties, in the order named, have given the best results.

Experiments with fodder beets, P. THIELE (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 4, pp. 143-146; 5, pp. 185-187; 6, pp. 207-209).—Variety and distance experiments are reported. Yellow Tannenkrüger and Yellow Eckendorfer gave the best yield of 11 varieties grown. Rows 14 in. apart gave better results than rows 12 in. apart.

Forage crops, W. B. ANDERSON (*Indiana Sta. Rpt. 1899*, pp. 59-66).—Notes on the culture and yield of the following forage plants grown at the station during the season: Corn, Kafir corn, sweet sorghum, Dwarf Essex rape, soy beans, cowpeas, field peas, vetches, and combinations of Canada field peas and oats. Cooperative experiments with some of these plants were carried out by farmers in different parts of the State, the results of which are briefly noted.

Forage crops other than grasses; how to cultivate, harvest, and use them, T. SHAW (*New York: Orange Judd Co., 1900*, pp. 287, figs. 29).—The author tells how to cultivate, harvest, and use for the purposes of forage, corn, sorghum, non-saccharine sorghums, plants of the clover family, other leguminous plants, rape, cabbage, the common cereals, millet, root crops, and miscellaneous plants. Chapters are given on successions of crops for continuous forage throughout the season in each of the different sections of the United States, and on sheep pastures at the Minnesota University Experiment Farm.

Fertilizer experiments with hops (*Bl. Gersten- Hopfen- u. Kartoffelbau*, 1 (1899), No. 9, pp. 322-330).—Summarized results obtained by the German Hop Culture Association in 1898.

Fertilizer experiments with hops, T. REMY (*Bl. Gersten- Hopfen- u. Kartoffelbau*, 1 (1899), No. 10, pp. 341-362).—Report on the use of different nitrogenous fertilizers for hops. The experiments were made at the Experimental Institute for Brewers in Berlin and, in cooperation with the institute, by growers in different hop districts in Germany. Barnyard manure was one of the best fertilizers used. Sulphate of ammonia and nitrate of soda proved good substitutes for this manure. Large amounts of potash in one experiment seemed to increase the total ether extract and resin content of the hops grown.

Notes on five years' experiments on hop manuring, B. DYER (*London: Vinton & Co., Ltd.*, 1900, pp. 21, figs. 12).—The object of these experiments has been "to ascertain how far nitrate of soda in the presence of an abundant supply of phosphates and potash can be advantageously used as a source of nitrogenous food for hops." Increasing amounts from 200 up to 400 lbs. per acre were used. The hops grown were examined independently by a brewing chemist and a commercial hop dealer, and their relative values judged. In no instance did the use of nitrate affect the quality of the hops injuriously. On the other hand, it considerably increased the total yield of hops, and had a decidedly beneficial effect on their quality as compared with hops grown on plats which received no nitrate. The author believes that on soils otherwise liberally manured 400 lbs. per acre of nitrate of soda is a perfectly safe dressing for hops. In the author's experience 600 lbs. per acre has given the best results in a dry year.

Culture of legumes, C. FRUWIRTH (*Anbau der Hülsenfrüchte. Berlin: Paul Parey*, 1898, pp. 274, figs. 69).—This is another contribution to the series of Thaer-Bibliothek agricultural books. The work is confined to podded plants such as beans, peas, and the like. The general part of the book treats of the botany of legumes, structure and development of the plant and seed, requirements as regards soil and fertilizers, basic principles in the culture of legumes, statistics of legume culture, uses of legumes, and place of legumes in a system of rotation, and as a salable seed crop. The special part, occupying little more than half of the book, is devoted to considerations of the botany, characteristics, culture, and uses of 24 species and varieties of legumes.

The present status of rice culture in the United States, S. A. KNAPP (*U. S. Dept. Agr., Division of Botany Bul.* 22, pp. 56, pls. 3).—This bulletin notes briefly the history of rice and its introduction into the United States, and gives in detail methods of rice culture in South Carolina, Georgia, Louisiana, and southeast Texas, dealing especially with systems of irrigation and the use of the gang plow, disk harrow, drill and broadcast seeder, and twine binder as applied to rice culture in southwest Louisiana and southeast Texas.

Historic and modern methods of milling rice are discussed, as well as the uses of rice and its by-products, soils adapted to rice culture, prospects for the extension of the industry in the United States, and the culture of rice in Asia and the Pacific Islands. Much statistical matter relative to imports of rice, production in the United States, etc., is also included in the bulletin.

Wild rice in Minnesota and Wisconsin, A. E. JENKS (*Amer. Thresherman*, 3 (1900), No. 2, pp. 18-54, figs. 9).—Methods followed by the native Indians in sowing and harvesting wild rice in these States are given.

Sugar-beet investigations in Wisconsin during 1898, F. W. WOLL (*Wisconsin Sta. Rpt.* 1899, pp. 249-262, fig. 1).—The data of this article have already appeared in Bulletin 71 of the station (*E. S. R.*, 11, p. 143).

Culture of sugar beets in Egypt, G. P. FOADEN (*Jour. Khediv. Agr. Soc. and School Agr.*, 2 (1900), No. 2, pp. 76-82).—Brief review of the sugar-beet industry in Germany and France, with notes on the present status of the industry in Egypt.

Applying phosphatic manure to sugar beets in the row (*Deut. Landw. Presse*, 27 (1900), No. 38, p. 472).—The yields of sugar beets were considerably increased when fertilizers were applied in the seed row over applications made broadcast.

Influence of increasing quantities of phosphoric acid and nitrogen in the culture of sugar beets, A. DAMSEAUX (*Bul. Agr. [Brussels]*, 15 (1899), No. 7, pp. 616–618).—Applying more than 700 kg. of superphosphate or 500 kg. of nitrate of soda in these tests was not profitable.

Sugar cane: Culture, manufacture, and statistics, W. TIEMANN (*Zuckerrohr: Kultur, Fabrikation, und Statistik*. Berlin: Deutscher kolonial Verlag, 1899, pp. 58).

Deep and shallow cultivation of cane in Audubon Park (*Louisiana Planter*, 24 (1900), No. 18, p. 285).—Shallow cultivation has given the best results. The author believes that this method of cultivation of cane in Louisiana would increase the yield of cane from 5 to 10 tons per acre.

The judging and culture of wheat for brewing purposes, T. REMY (*Bl. Gersten-Hopfen- u. Kartoffelbau*, 1 (1899), No. 9, pp. 305–316).

Field tests of varieties of wheat, covering nineteen years, W. C. LATTA (*Indiana Sta. Rpt.* 1899, pp. 54–58).—Tabulated data showing the average yield and the characteristics of the grain and straw of 178 varieties of winter wheat and 11 varieties of spring wheat tested at the station during the preceding 19 years, with notes and comments.

HORTICULTURE.

A study of the effect of incandescent gaslight on plant growth, L. C. CORBETT (*West Virginia Sta. Bul.* 62, pp. 79–110, pls. 9, figs. 4, charts 7).—This bulletin reports the results obtained in a series of greenhouse experiments carried on during the years 1895 to 1899 with lettuce, radishes, spinach, tomatoes, sugar beets, and seedling cabbage, mainly from an economic standpoint. Eight Welsbach incandescent burners were used in the experiments, and these were so alternated in position from time to time as to overcome local temperature and light differences. Plans of the greenhouse used and photographic, diagrammatic, and auxanometer records of the growth and development of the different crops form an important part of the bulletin. Weighings of the crops were made and the sugar beets grown analyzed. The character and quality of the arc and incandescent electric lights and Welsbach gaslight as compared with sunlight are discussed by the aid of figures.

The experiments with lettuce involved 12 distinct crops and nearly 10,000 plants. Transplanting the young plants from pots and using an artificial light only during the period the plant occupied the permanent greenhouse bench was adopted after comparative trials as being the best method for the growing of lettuce on a commercial scale. The plants grown in artificial light were taller, heavier, grew faster, and matured quicker than plants grown from the same lot of seed under normal conditions. In one experiment 400 plants exposed to the stimulating influences of the artificial light for 46 nights weighed 68.56 lbs., while a similar lot grown under normal conditions weighed 49.43 lbs., an increase in favor of the former of 38.7 per cent.

Radishes were grown between the rows of lettuce, as is commonly practiced in commercial houses. The artificial light notably increased the development of the tops of the radishes and slightly increased the size of the roots. The heliotropic effect of the incandescent light was greater with radishes than with any of the other plants grown. The stimulating influence of the incandescent light, on the other hand, was greatest with spinach. It caused the production of seed shoots in the row to a distance of nearly 8 ft. from the light. Spinach plants subject to the influence of the light grew faster and completed their growth in less time than plants grown normally.

The records of the yield and date of first bloom of tomatoes grown from seed and also from cuttings show no increase in weight of the fruit grown in the light, though the blossoming period was from 8 to 18 days earlier and the individual fruits were generally larger than when grown under normal conditions.

With sugar beets the tops, sugar content of the roots, and percentage of purity were considerably increased by the use of the incandescent gaslight. The largest and heaviest roots, however, were grown under normal conditions.

The range of stimulating influence of the incandescent light was studied.

"The range of light is somewhat variable for different crops. In general the maximum growth was attained at 12 to 16 ft. from the light, while a perceptible increase was noted at 24 ft.

"The stimulating influence of the light as indicated by the growth of plants used in the various tests is shown by the order in which the sorts are named, the first being the most susceptible: Spinach, cabbage, radish, lettuce, tomato."

In a study of the periodicity of plant growth as modified by the influence of the artificial light it was found that the most active period of growth of lettuce subject to the influence of the incandescent gaslight began at 11 p. m. and continued until 9 a. m., while with the plants grown under normal conditions the most active period of growth began at 4 a. m. and continued until 11 a. m. In the first instance the period of growth was 10 hours and in the second 7.

In these experiments no injurious effects resulted from the use of incandescent gaslight.

The use of chemical fertilizers in the forcing house, W. STUART (*Amer. Gard.*, 21 (1900), No. 268, p. 94).—This article summarizes the experience of the Indiana Station in the use of commercial fertilizers for forcing lettuce under glass. The results are at variance with those reported by A. T. Jordan (*E. S. R.*, 11, p. 1039), the statement there made that "chemical fertilizers are of little use in the forcing house" being criticised.

In one test at the Indiana Station the soil used was composed of a black loam sod composted with one-fourth of its bulk of manure. The soil to which the commercial fertilizers were applied for comparison

was taken from underneath the sod used in the prepared soil just noted, "and was, therefore, poorer both in plant food and mechanical mixture." The author states that the leaves of the plants grown in the rotted sod and manure were softer, more leathery, and therefore less crisp and tender than those grown in the pots fertilized with the commercial fertilizers, and did not keep so well when marketed. "Plants grown in the prepared soil and manure averaged 157.7 gm. in weight, while those grown in the poorer soil with the addition of a liberal dressing of raw bone meal averaged 169.3 gm. per plant, an increase in favor of the latter of over 7 per cent."

In another experiment a pot of the same soil to which commercial fertilizers were added was mixed with an equal bulk of well-rotted manure. The average weights of plants grown under the different conditions are as follows:

"Soil and manure, 323 gm.; raw bone meal, 286 gm.; raw bone meal, nitrate of soda, and muriate of potash, 334 gm. The increased product from the third lot over that of the first, while only slight, is yet sufficiently marked to show the value of chemical fertilizers in the forcing house. . . . Our best results have been obtained with raw bone meal, nitrate of soda, and muriate of potash. The last 2 ingredients, because of their immediate availability, should be used in moderate amounts, and, in the case of nitrate of soda at least, should be applied in from 2 to 4 installments."

The effect of transplanting on time of maturity, F. CRANFIELD (*Wisconsin Sta. Rpt. 1899, pp. 312-315*).—Tests were made to determine the correctness of the commonly accepted opinion that transplanting promotes earliness and increases yield. Trials were made with a number of vegetables both in the greenhouse and in the open field. Seeds of Grand Rapids lettuce were sown in a greenhouse on January 15. February 5 one-half of the plants were taken up and reset in the same places in the usual manner of transplanting seedlings. March 23 the entire crop was cut and weighed. The average weight of the plants not transplanted was 42.4 gm., while the average weight of the transplanted plants was only 36.4 gm., showing a gain of $16\frac{2}{3}$ per cent in favor of the plants that were not transplanted.

In another trial cabbage seed was sown February 5. February 28 two-thirds of the plants were transplanted as in the previous trial, and March 8 one-half of the transplanted plants were again transplanted. May 3, 8 plants from each lot were cut and weighed. The plants that had not been transplanted weighed 4,214 gm. Those that had been transplanted once weighed 2,993.5 gm. and those that had been transplanted twice weighed 2,241.7 gm. "In this case the once-transplanted plants fell 28.9 per cent behind the not transplanted, and those twice transplanted fell 46 per cent behind the not transplanted. Several other trials were made in the greenhouse with lettuce and radishes, and all gave similar results."

In a similar way 3 crops of tomatoes were grown. In each case seeds were planted singly in flowerpots in the greenhouse. As in the

case of the cabbage, one-third of the plants were not transplanted, one-third transplanted once, and one-third transplanted twice. As soon as the weather permitted, 10 plants from each lot were taken from the pots and transferred to the open ground, every precaution being taken to avoid injury to the roots. The total yield of fruit in 3 years by the plants that had not been transplanted was 1,174.8 lbs. Those that had been transplanted once yielded 1,131.2 lbs. and those that had been transplanted twice 1,001.2 lbs.

In order to judge of the influence of transplanting on earliness, the ripening season was divided into 3 parts and the yield calculated separately for each part. During the first period the yield of the plants that had not been transplanted was 105.2 lbs. Those that had been transplanted once yielded during the same period 109.7 lbs., while those that had been transplanted twice yielded but 88.1 lbs.

Experiments were also made in the open field with cauliflower, kale, collards, and two varieties of cabbage, the results showing a gain in every case in favor of those plants that were not transplanted.

The conclusions, based on 3 years of experiment, are stated as follows:

"Lettuce and other plants in the greenhouse, when given sufficient room to develop and not transplanted, matured quicker and produced a greater yield than similar plants that had been transplanted. In the case of tomatoes there was a slight gain in earliness and yield in favor of the not transplanted plants, while those twice transplanted were very evidently injured. Cabbage and allied plants when grown wholly in the open ground were perceptibly injured by transplanting.

"The general conclusion drawn from this work is that transplanting does not promote earliness nor an increased yield. Once transplanting, as of cabbage plants, from the seed bed to the field, or 'pricking off,' as commonly practiced in the greenhouse, is necessary in order to economize room, but repeated transplanting of vegetable plants is not advisable."

Report of the horticulturist, A. L. QUAINANCE (*Georgia Sta. Rpt. 1899, pp. 123-139*).—The effects of the freeze of February 13, 1899, on orchard fruits are discussed, and tables are given showing the results on 45 varieties of Japanese plums. As a whole, these suffered more than peaches, some being entirely killed. Figs and Japanese persimmons were killed to the ground. The injury to grapes was light, though the varieties Eden and Scuppernong were seriously injured. Apples, cherries, quinces, and native plums were not perceptibly injured by the freeze.

Tables are given showing the effect of ringing on 195 varieties of grapes, especially with reference to earliness and keeping qualities. The results for the season show that the time of keeping of 22 varieties was somewhat prolonged by ringing; with 60 varieties it was shortened from 1 to 7 days.

Brief notes are given on the growth of onions, sweet corn, celery, and asparagus. Applications of common salt did not increase the

yield of asparagus, and when 5 tons of kainit were applied per acre the yield was only slightly increased. The variety Palmetto gave the best yield of 4 varieties tested. The greatest yields with asparagus were obtained from plants set 18 in. apart in 4-foot rows. The shoots of these plants, however, were small, and for choice cuttings it is suggested that plants should not be set closer than 4 by 4 ft.

Field notes of horticultural department, C. B. WALDRON (*North Dakota Sta. Bul. 42, pp. 493-533*).—The influence of different fertilizers on the total yield and time of maturity of vegetables in the Red River Valley are reported for the years 1898 and 1899. The soil selected was typical of the whole valley. Different varieties of beets, onions, cucumbers, cabbage, lettuce, tomatoes, beans, radishes, peas, and carrots were grown, each being fertilized with a complete fertilizer, superphosphate, kainit, nitrate of soda, salt, lime, and stable manure, respectively. The results are recorded in 54 tables. In no case was there sufficient increase due to the fertilizers to warrant their application, and it is thought that the method of handling the soil has more to do with the production of vegetables in this valley than the application of fertilizers. Transplanting onions, even the ordinary sorts, proved profitable.

Preliminary report on experiments in pinching raspberry shoots, E. S. GOFF (*Wisconsin Sta. Rpt. 1899, pp. 275-282, pl. 1*).—Experiments made to ascertain to what extent the pinching of the tips of raspberry shoots promotes productiveness and increases the size of fruit are reported. In the first experiment 6 rows each of Cuthbert (*Rubus strigosus*) and Gregg (*R. occidentalis*) raspberries were used. "Two rows of each variety were left unpinched; two other rows had the shoots pinched as they attained the height of about 12 in.; the remaining two rows of each variety had the shoots pinched at about 12 in. high; and in addition the branches were pinched as they attained the length of about 12 in. from the main shoot." The result of the experiment was that the canes which were not pinched at all yielded slightly more than those that were pinched, the difference being rather the more noticeable with the Cuthbert variety.

To ascertain the effect of pinching the shoots on the size of the berry, 100 were taken by chance from each plat and weighed.

"The pinching appeared to increase the size of the fruit a little, especially in the Cuthbert variety.

"No difference could be observed in the different methods of pinching as to the susceptibility of the plants to disease. It was observed, however, that the shoots that were not pinched at all were killed back a little farther in winter than those that were pinched. The shoots appeared to be more numerous in the pinched than in the unpinched rows, and most numerous in the rows in which both the shoots and laterals were pinched. This indication was fully confirmed when one of the plantations was rooted out. The stumps from the unpinched rows showed the fewest stubs of canes, and those from the twice-pinched rows showed the most."

This experiment was not satisfactory for several reasons, and a second and more extended one was undertaken. Two-thirds of an acre was divided into 2 equal parts, one of which was planted to Gregg and the other to Cuthbert raspberries. Each of these plats was further subdivided into 3 plats.

"Each of these 3 plats was again subdivided into 3 smaller plats, containing 3 rows each. Each of these 3-row plats had 1 row that was left unpinched, 1 row of which the shoots only were pinched, and 1 row in which both the shoots and laterals were pinched. In the first plat of each variety, the shoots in the pinched rows were pinched at 12 in. high; in the second plat they were pinched at 18 in. high; and in the third plat at 24 in. high. Four shoots only were permitted to grow to each plant. The plantation was carefully gone over at frequent intervals and every shoot in the pinched rows was pinched at nearly the designated height. The superfluous shoots and suckers were removed from each row and either counted or weighed."

The results of the experiment indicated: "(1) That the high-pinched rows yielded more fruit than the low-pinched rows; (2) that the high-pinched rows yielded more fruit than the rows that were not pinched; (3) that twice pinching gave no advantage in yield over once pinching; (4) that the influence of the pinching is quite as marked in the Cuthbert variety as in the Gregg, and it seems to have been exerted in the same direction."

Observations were made on the effect of pinching on growth of superfluous shoots and suckers. The results are shown in tabular form.

"The data clearly indicate that pinching the shoots stimulates the growth of superfluous shoots and suckers. Pinching both the shoots and laterals appears to stimulate the superfluous growth less than pinching the shoots only. This is probably because the second pinching, coming later in the season than the first, and being made on a larger number of shoots, is a much more effectual check to growth than is the first pinching."

Observations were also made on the effect of pinching upon the height and stockiness of the stems and upon the labor of covering them for winter. As a result of these experiments the author is of the opinion that the importance of pinching as a means of keeping the growth of stems within bounds has probably been overestimated.

In the experiments there was but little difference as regards height of canes and spread of branches between the plants pinched and those unpinched; but the labor of covering the former was fully one-third greater. The stems were decidedly more brittle and the branches were more numerous in the pinched rows.

The experiments are to be continued. The following conclusions are drawn from the data obtained up to the present time:

"In young plantations of the Gregg and Cuthbert raspberries grown under the conditions noted for these experiments, pinching the shoots high, *i. e.*, when about 24 in. tall, is beneficial to the yield, but that pinching at 12 in. high is of very doubt-

ful value, as is shown in both experiments; also, that pinching the lateral shoots is not beneficial to the yield, and that pinching increases the growth of superfluous shoots, and, in the Cuthbert variety, of suckers. Pinching also increases the cost of covering for winter protection."

Preserving fruit for exhibition, F. CRANFIELD (*Wisconsin Sta. Rpt. 1899, pp. 309-311, figs. 2*).—Trials were made with a view to finding a method of preserving fruit for exhibition purposes that would preserve the color of the fruit as far as possible and at the same time the form. Sulphur fumes, corrosive sublimate, salicylic acid, and solutions of formalin in water were tried and found to be of little value. Mixtures of formalin and alcohol were tried, however, as preservatives for plums with considerable success. A formula containing 2 per cent of formalin, 20 per cent of alcohol, and 78 per cent of water was found to be best suited to the purpose.

"Plums put in the above mixture one year ago are at present well preserved. The fruit remains firm, and in the case of the lighter colored varieties the color is well preserved and the liquid remains clear. The color was not so well preserved in the case of the dark-purple varieties. The Japan plums are especially well preserved both in color and form. . . . Plums that were put in the mixture slightly immature cracked badly in every case, while those put in fully ripe remained without cracking. Currants, raspberries, and blackberries placed in the formalin and alcohol mixture mentioned above remained firm, but the color was not well preserved."

Rose growing with chemical fertilizers, W. STUART (*Indiana Sta. Rpt. 1899, pp. 10-35, pls. 4*).—Extensive pot experiments covering a period of 3 years were made in fertilizing Kaiserin Augusta Victoria and Perle des Jardins roses with dissolved boneblack, rock phosphate, raw bone meal, acidulated ground bone, superphosphate, nitrate of soda, and muriate of potash, for the purpose of studying the relative effects of different forms of phosphoric acid alone and conjointly with nitrate of soda and muriate of potash, on growing roses. A clayey soil was generally employed. In some instances black loam was used for comparison. The detailed results obtained with the different fertilizers and soils are reported exhaustively in a series of 20 tables. The author summarizes his conclusions as regards the results obtained as follows:

"There is every reason to believe from the results obtained in the several experiments, that chemical fertilizers when properly used may be made to serve every need of the rose plant so far as food is concerned.

"The use of raw bone meal in every instance gave an increased yield over that of the control plants, as well as giving a greater percentage of gain than did those receiving other forms of phosphoric acid.

"Pure bone meal is not injurious to rose plants, even when applied in amounts largely in excess of the requirements of the plant.

"The acidulated bone meal, which has been used by florists and supposed to be harmful, did not produce any noticeable injury, even when used in large amounts.

"As a rule, a combination of phosphoric acid and nitrate of soda gave better results than one of phosphoric acid and muriate of potash.

"Two or three applications of potash during the season was found to be preferable to a single application, although in some instances no injury from the single application was apparent.

"A larger number of Perle roses were produced from plants grown in a black than in a clay loam, while the Kaiserin gave reverse results.

"The subwatering method proved an efficient means of supplying the plants with moisture."

Rose thrips were controlled in these experiments by frequent spraying with a solution of Rose Leaf Extract of Tobacco, 1 part of the extract to 75 parts of water.

Our gardens, S. R. HOLE (*London: J. M. Dent & Co., 1899, pp. 304, pls. 8*).—Deals with the history and development of English gardens, the formation of a garden, its constituent parts, herbaceous borders, and containing chapters on each of the subjects, rose, rock, water, wild, cottage, children's, town, and other gardens. Suitable plants are suggested in each instance and their characters given.

Variations produced by grafting, and their inheritance (*Gard. Chron., 27 (1900), Nos. 680, pp. 12, 13; 682, pp. 35, 36; 685, pp. 85, 86; 687, p. 116*).—Showing variations in growth, form, flowering, and chemical constitution. The article is based on work by L. Daniel (*E. S. R., 11, p. 343*).

Preservation of fruits, vegetables, seeds, and bulbs, H. COUPIN (*La conservation des fruits des légumes, des graines, et des racines bulbeuses. Paris: Octave Doin, 1899, pp. 172, figs. 6*).—A chapter is devoted to each of the above subjects, and the material in each chapter arranged alphabetically. With the fruits and vegetables most attention is given to their preservation in the fresh and in the dried state. Under seeds, duration of vitality and preservation against insect enemies are considered. The chapter on bulbs gives directions for keeping a number of flowering sorts.

Experiments in forcing vegetables, J. TROOP (*Indiana Sta. Rpt. 1899, pp. 82, 83*).—These consisted of subwatering v. surface-watering experiments with tomatoes and lettuce, and of fertilizing experiments with lettuce and peas. The results of the tests are given but no conclusions are drawn.

The new asparagus culture, G. M. HAY (*Amer. Gard., 21 (1900), No. 282, p. 344*).—The details of growing asparagus from seed suitable for cutting 2 years from date of sowing are given.

An experiment in pruning old trees, H. A. ALDRICH (*Trans. Illinois State Hort. Soc., 1899, pp. 48-54*).—Old trees which had been subject to nonbearing for years were given over to thorough pruning, the whole top being headed in from 1 to 3 ft. A yield of 20 to 30 bu. of apples per tree was obtained the first season, besides a good growth of new wood.

Seaweed for fruit trees (*Agr. Jour. Cape Good Hope, 16 (1900), No. 4, pp. 231, 232*).—A brief note on the successful use of seaweed as a fertilizer and as a mulch for fruit trees.

New varieties of fruit not yet generally introduced, S. A. BEACH (*Proc. West. New York Hort. Soc., 1900, pp. 34-41*).—Notes on the quality and character of 12 varieties of apples, 2 of Japanese plums, 2 of grapes, and 2 of Domestic plums, as yet little grown.

Note on the cider fruits of Germany—apples and pears, A. TRUELLE (*Note sur les fruits de pression Allemand—pommes et poires. Rennes: V. L. Caillot, 1899, pp. 44*).—The varieties of apples and pears most used for cider in Germany are described and tables given showing their composition.

Russian apples in Indiana, J. TROOP (*Indiana Sta. Rpt. 1899, pp. 78-81*).—Notes on 43 varieties of Russian apples which fruited at the station during the season. "Not one variety in the whole list can be classed as a winter apple in Indiana."

Investigations made by the State Board of Horticulture of the California olive industry (*Sacramento*, 1900, pp. 83, figs. 39).—The history of olive growing in California, methods of propagation, soils, causes of unfruitfulness, pruning, grafting, budding, varieties, methods of extracting the oil, packing, apparatus, pickling, processing, grading, and pests affecting olives are popularly considered. The work is based wholly on California conditions, methods, and practices.

Culture of the olive, N. MINANGOIN (*Bul. Dir. Agr. et Com.*, 5 (1900), No. 15, pp. 46-63).—Systems and methods of culture of the olive employed in Tunis.

The Russian olive, C. S. HARRISON (*Amer. Gard.*, 21 (1900), No. 286, p. 405, fig. 1).—History and description of this ornamental tree in Nebraska.

The peach, C. TRÉBIGNARD (*Rev. Hort. et Vit.*, 32 (1900), No. 6, pp. 110-118, figs. 2).—Types of fruit branches and pruning are considered.

The service tree and its fruits, A. TRUELLE (*Du sorbus domestica et de ses fruits. Alençon: E. Renault de Broise*, 1898, pp. 23).—This discusses the varieties and uses of this fruit in the different countries of Europe and gives directions for its propagation and culture.

Culture of tree and bush fruits, A. DU BREUIL (*Culture des arbres et arbrisseaux à fruits de table. Paris: G. Masson*, pp. 693, figs. 55).—In the general part of this work all the operations of the orchard are considered. The special part takes up all the more important orchard fruits, including citrus fruits, figs, apples, pears, cherries, and the like, table grapes, nuts, etc., and gives complete cultural directions for each.

Analysis of prickly pear, C. F. JURITZ (*Rpt. Senior Analyst, Cape Good Hope*, 1898, pp. 63-66).—The composition of the young and older leaves, stalk, and inner portion of the stalk of the prickly pear is reported.

The culture of coffee (*Bol. Agr. Min. é Ind. [México]*, 9 (1899), No. 3, pp. 4-172, figs. 23).—A comprehensive article on the history, botany, chemistry, culture, and manufacture of coffee.

The establishment of a coffee plantation, F. W. MORREN (*Beihfte Tropenplanzer*, 1 (1900), Nos. 2, pp. 39-71, figs. 8; 3, pp. 75-118, figs. 6).—Directions for preparing the land, planting, manuring, cultivating, and pruning the trees, and harvesting the crop, with notes on injurious insects and diseases affecting the trees.

Present status of coffee culture in Brazil, F. W. DAFERT (*Ueber die gegenwärtige Lage des Kaffeebaus in Brasilien. Amsterdam: J. H. de Bussy*, 1898, pp. 63, charts 4).

A cocoanut analysis, F. BACHOFEN (*Queensland Agr. Jour.*, 6 (1900), No. 4, p. 297).—The draft of the cocoanut on the soil is shown by the ash analyses reported of the husk, shell, kernel, and milk of the fruit.

Manual of practical viticulture, E. DURAND (*Manuel de viticulture pratique. Paris: J. B. Baillière & Sons*, 1900, pp. 424, figs. 147).—Chapters are given on the organography and physiology of the vine, biological cycle, climate and soils, propagation, cultivation, pruning, training, manuring, pests, and like subjects, making the work a very complete treatise on practical viticulture.

Some hints on ornamental planting, C. B. WALDRON (*North Dakota Sta. Bul.* 41, pp. 471-491, figs. 3).—Popular suggestions to the farmers of the Northwest on the planting of ornamental and economic trees and shrubs, with notes on some of the more essential principles of landscape gardening. There is appended a paper on "Locating shrubs for effect," by F. H. Nutter, and a table of hardiness of deciduous trees and ornamental shrubs and vines taken from Minnesota Station Bul. 24 (E. S. R., 4, p. 653).

DISEASES OF PLANTS.

Notes on various plant diseases, F. C. STEWART (*New York State Sta. Bul.* 164, pp. 207-221, pls. 4).—Notes are given on a bacterial rot of onions, powdery mildew on field-grown cucumbers, dodder on cucumbers under glass, on the possible cause of the Baldwin fruit spot,

a fusarium leaf spot of carnations, and *Chaetomium contortum* on barley seedlings.

In the summer of 1898 it was reported to the station that in the onion region of Orange County, N. Y., the bulbs were rotting badly, and upon investigation it was found that in nearly all the fields there was a considerable amount of rot. Two forms were recognized, one which starts at the bottom of the onion and the second which starts at the top or neck. The latter kind was much more common and constituted probably 80 per cent of the total amount of rot. Upon cutting open the affected bulbs, it was generally found that 2 or 3 of the outer scales were perfectly sound, while the remainder of the bulb was a rotten mass. Microscopic examinations of the rotten tissues showed the absence of fungi, but there were swarms of a medium-sized motile bacillus which doubtless causes the rot. Bulbs so affected showed in addition a growth of fusarium, which aids materially in destroying the onions, and in some cases this may be the primary cause. As yet no attempt has been made to determine the identity of the organism causing the disease. Experiments were conducted in the laboratory which showed the necessity of an abundant water supply for the production of the disease, and as the onion fields had been frequently inundated on account of the heavy rainfall during the season, the conditions were favorable for the presence and rapid spread of the disease.

The powdery mildew on field-grown cucumbers is reported by the station, although the identity of the fungus is a matter of some conjecture. While powdery mildew has been known to occur on cucumbers grown under glass, this is probably the first report of its occurrence in the field. There seems to be little likelihood of its becoming epidemic, and should it do so, it probably would not be difficult to control.

The author reports the occurrence of dodder, probably *Cuscuta groenovi*, on cucumber plants grown in the station hothouse.

Investigations were conducted to determine whether the Baldwin fruit spot is caused by fungi or bacteria. This disease, which is quite characteristic on the Baldwin apple, occurs in the form of conspicuous spots on the surface of the fruit. The spots vary in color from light to dark brown, are generally circular in outline, although sometimes quite irregular, but always with the corners well rounded and sharply delimited from healthy tissue. Underneath the surface spots the tissue is light brown, dry, and spongy for a distance of $\frac{1}{4}$ to $\frac{3}{16}$ in. This spongy tissue is not bitter to the taste, or at least but slightly so. Microscopic examination of the tissue revealed no fungi or bacteria which could be definitely demonstrated. From the results of the author's study, he concludes that this form of apple fruit spot is not caused by fungi or bacteria and that the real cause is unknown.

A report is given of a fusarium occurring on the carnation, resulting in leaf spot. The plants had been growing under conditions espe-

cially favorable to fungi, being situated so that the direct sunlight never reached them. The spots varied in length from $\frac{1}{8}$ to 1 in. and were covered by a pinkish-gray mold dotted in the center with yellow spore masses of the fusarium. The fungus was evidently parasitic on the leaves, but careful examination revealed the fact that in every case the spots originated in a rust sorus. It appeared that the fungus was unable to attack the uninjured leaf, but when the epidermis was broken by rust, it was able to enter and bring about the decay. Inoculation experiments, it is thought, will show that this fungus is identical with that causing carnation stem rot.

A report is given of the occurrence on barley seedlings of the perithecia of *Chaetomium contortum*. This fungus was previously noted as occurring on lily bulbs in a greenhouse on Long Island, where it was discovered by the author in 1895. No report had been made of the occurrence of this fungus from that time until the present, when it was found on barley. The indications are that it is not parasitic, but that the spores had become attached to the barley seeds before they were planted.

Corn smut, J. C. ARTHUR and W. STUART (*Indiana Sta. Rpt. 1899, pp. 84-135, pls. 4, chart 1*).—A detailed report is given on corn smut, the investigations of the authors and others being drawn upon. Corn-smut experiments have been conducted at the station for about 10 years, in which the life history of the fungus has been studied, together with possibilities of discovering methods for prevention. An historical résumé is given of the experiments with corn smut, the proper scientific name of which the author claims is *Ustilago zae*. The life history of the fungus, as shown by the development of the spores, etc., is described at considerable length. The influence of weather and maturity on infection, the distribution of the smut pustules over the plant, and prevention by spraying are discussed at some length. Details of some of these investigations have been previously reported (*E. S. R.*, 8, p. 317).

Experiments in which corn plants were sprayed with Bordeaux mixture and other fungicides showed that the disease can be controlled, but the economic consideration places such treatment out of the possibility of utilization. It is recommended that all smut masses be destroyed by burning or putting in boiling water. The effect of smut on animals, as shown by a careful review of literature, is given, together with notes on the digestibility of the smut fungus. A summary is given by the authors of their investigations, and an extensive bibliography on the subject completes the report.

Club root, W. HAWK (*Rpt. Agr. Expts. Cornwall County Council 1898, pp. 27-42, pls. 7*).—Experiments in the treatment of club root of turnips are reported. Lime was applied in different quantities at various depths and at different seasons. A plat of land receiving 6

tons of lime per acre and frequently cultivated to a depth of about 3 in. yielded, with a basic slag fertilizer, 18 tons, 952 lbs. of roots per acre, and with superphosphate, 11 tons, 308 lbs. of roots per acre. On the basic slag the number of sound roots per pole was 156, and of diseased roots, 126. On the superphosphate the number of sound roots was 54, and of diseased roots 132.

Another plat similarly treated in all respects, with the single exception that it was cultivated only occasionally and then to the depth of only $\frac{1}{2}$ in., yielded, with slag, 13 tons, 644 lbs. of roots per acre, and with superphosphate, 9 tons, 1,904 lbs. On the slag in this case the number of sound roots per pole was 102 and the number of diseased roots 186. On the superphosphate there were only 60 sound roots per pole, but 144 diseased roots. "It will be seen that both on the slag and superphosphate halves of the plats the figures are conclusively favorable to the thorough incorporation of the lime with the soil."

In studying the quantity of lime that should be applied, the plats just referred to, receiving 6 tons of lime per acre, were compared with similar plats receiving 8 tons per acre. The turnips on slag receiving 6 tons of lime per acre yielded 18 tons, 952 lbs. of roots per acre, while the plat treated with 8 tons of lime produced only 18 tons; but on the plat receiving 8 tons of lime, more than 5 out of every 6 roots were sound, while on the other plat nearly one-half of the roots were more or less diseased. The figures for the plats receiving superphosphate were very different, but the general results were the same. The yields of turnips on the plats receiving basic slag and those receiving superphosphate, as reported in the first experiment above, are, as already indicated, highly favorable to slag; but when the lime was applied in June instead of in the autumn, as in that case, the amount of yield on the respective plats was reversed, but was in each case much less than when lime was applied in the fall.

Tests of kainit and sulphate of iron showed that both were equally powerless to check the disease. Sulphate of copper checked the disease to a small extent. Experiments are now in progress to determine whether the micro-organism causing the disease can survive passage through an animal.

Apple-tree anthracnose, A. B. CORDLEY (*Oregon Sta. Bul.* 60, pp. 8, pls. 3).—For several years there has been known in the apple orchards of western Oregon, Washington, and British Columbia a more or less serious disease which is locally known as canker, dead spot, or black spot. Investigations on the part of the author have led him to the conclusion that this is an undescribed disease caused by a species of *Gloeosporium*, to which the name *G. malicorticis* has been given. In order to avoid confusion, he proposes for this disease the common name apple-tree anthracnose.

The disease principally attacks the smaller branches, although occurring sometimes on the larger ones and often on the trunks of young trees. It appears in the fall, soon after the autumn rains begin, as small, irregular, slightly depressed brown areas of the bark. During the fall and winter its spread is very slow, but with the recurrence of spring it spreads rapidly, until an area of several inches in diameter is infected. Occasionally a single area completely girdles a branch, killing at once its distal portion, but more commonly a dead spot occurs, from which, in the course of a few months, the bark sloughs off, leaving an ugly wound, which heals very slowly. The cause of the disease is mentioned and the fungus briefly characterized. The fungus has been isolated and grown on various cultures and inoculation experiments successfully made.

As possible remedies, the author suggests the use of Bordeaux mixture or ammoniacal copper carbonate, together with pruning of badly infested trees.

The New York apple-tree canker, W. PADDOCK (*New York State Sta. Bul.* 163, pp. 179-206, pls. 6).—In 1898 the station authorities were requested to investigate the cause of the dying of trees in an orchard in East Bloomfield, N. Y. The orchard in question originally consisted of 125 acres. The trees on 30 of the 80 acres in one part were ruined by the canker and had been taken out, and one-half of the trees on the remaining 50 acres are now of little value.

The owners have noticed the disease for at least 6 or 8 years, but it has increased rapidly only in the last 3 or 4 years. It showed a decided preference for certain varieties, the Twenty Ounce being the most susceptible, followed by Baldwin, Wagener, Greening, and King, in the order named. Tallman Sweet appears to be practically free from the disease.

Investigations as to the possible cause of the disease resulted in the discovery that it was due to the same cause as the black rot of the apple (*Sphaeropsis malorum*). More than 50 successful inoculations were made in 1898, and in 1899 the experiments were repeated many times with the same result.

The geographical distribution of the fungus, as determined from circular letters sent to various stations, is as follows: Connecticut, Indiana, Maryland, Michigan, Pennsylvania, and Vermont, and probably in Illinois, Maine, Massachusetts, Minnesota, New Jersey, West Virginia, and portions of Canada.

The author thinks it probable that when the disease becomes more generally known it will be found in many of the apple-growing sections of the Northern, Central, and New England States.

The appearance of the disease may be recognized by the occurrence of dark enlarged sections on the larger limbs which, upon closer exami-

nation, show a much roughened and thickened bark, and in many instances a portion of the wood is laid bare. The dead bark on many diseased limbs clings tenaciously to the decaying wood, which is a feature that distinguishes this canker from sun scald. The area of bare wood is often small as compared with the extent of swollen bark. The progress of the disease is marked by numerous pits and scars, showing where the fungus was able to live until it gained entrance to the cambium through some injury. The scars are usually circular in form and may be outlined by 2 or more concentric lines. The fungus shows a preference for the larger limbs of mature trees, although the trunks and branches of young trees, as well as the small limbs and twigs of a current season's growth, suffer from its attack. While the extent of injury done to the orchards can scarcely be estimated, it is the author's belief that it is one of the worst diseases which the orchardist will have to contend with, since it attacks the tree directly instead of the foliage.

Infection, it is stated, takes place in the spring of the year, and the presence of the fungus is indicated in a newly-infected limb by the appearance of a small area of discolored bark. This area extends slowly as the fungus grows outward until midsummer, when a definite boundary forms between the dead and living bark. The season's growth is stopped by the 1st of August, and in some instances pycnidia containing mature spores were found at that time. The mycelium was unable to penetrate to the cambium through the living bark, but those spores which chanced to fall and germinate in a wound produced the cankers. There is some evidence that the mycelium lives over winter and continues its growth the following spring.

Among preventive measures, the author recommends that special attention should be paid to the sanitary condition of the trees. The practice of scraping and whitewashing the trunks, now largely in disfavor, is recommended for adoption in localities where canker is severe; also washing the trees with a whale-oil soap mixture, spraying with Bordeaux mixture, cutting out cankered limbs, and covering the wounds with Bordeaux mixture or some other fungicide. The time for spraying is given, the first application to be made at the time that the leaf buds begin to open, a second a week before the blossom buds open, a third as soon as all the blossoms have fallen, and a fourth 10 days or 2 weeks later.

The investigations of this disease were continued in 1899, and it was found that a number of fruit trees are attacked by species of *Sphaeropsis*. The author's investigation would seem to indicate that the number of species can be materially reduced, since there is great probability of the same species occurring in a slightly modified form upon a number of hosts.

In 1898, while preliminary studies in apple canker were being conducted, a body blight of pear trees was discovered in which a *Sphaeropsis* was found abundant, commonly associated with *Macrophoma malorum*.

Notes are given on a Pacific-coast apple-tree anthracnose, which is described elsewhere (E. S. R., 12, p. 58), and a European canker due to species of *Nectria*.

Plant diseases, A. L. QUAINANCE (*Georgia Sta. Rpt. 1899*, pp. 139-141).—Brief notes are given on the occurrence of a number of diseases, with suggestions for their prevention. Among those enumerated are the *Macrosporium* disease of tomato plants and eggplants, *Sclerotium* disease of Irish potatoes and tomatoes, a rot of tomatoes, the black rot of grapes, the brown rot of grapes, celery blight, and soft rot of sweet potatoes.

Divers diseases discussed, F. H. HALL (*New York State Sta. Bul. 164*, popular ed., pp. 5).—A popular edition of Bulletin 164 of this station, in which a number of plant diseases are discussed (see p. 55).

Report of the botanist, C. E. BESSEY (*Rpt. Nebraska State Bd. Agr. 1898*, pp. 139-161).—A preliminary account of the diseases of the farm crops of Nebraska.

The diseases of the potato, E. GAIN (*Sta. Agron. Nancy Bul. 1*, 1899, pp. 40-51).—The author divides the diseases of the potato into 2 categories based upon their importance. In the first are placed the dry rot, wet rot, *Phytophthora*, and a spot disease called *frizolée*. In the second class are considered potato scab, *Rhizoctonia*, a disease due to *Spongospora solani*, and the greening of the tubers. The causes of these various diseases are described, together with their effects upon the host plants, and suggestions are given wherever known for the prevention of the diseases.

Smut in wheat (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 3, pp. 147-152).

Gumming disease in cane (*Internat. Sugar Jour.*, 2 (1900), No. 14, pp. 97, 98).

Asparagus rust, P. H. ROLES (*South Carolina Sta. Rpt. 1899*, p. 17).—Asparagus seed from a field of rusted asparagus carried many spores, although the berries did not appear to be diseased. "Though direct evidence is wanting, it seems altogether probable that seedlings raised from such seeds would contract the disease." Uredo spores were found on stocks of two-year-old plants in a diseased field two or three inches below the surface of the ground. In such cases burning over the beds, which has sometimes been recommended, would not eradicate the disease. It is not considered advisable to plant seed gathered from a rusted field, nor to set out a plantation with plants from such a source.

Fruit tree enemies, E. H. POTTER (*Gard. Chron.*, 3. ser., 27 (1900), No. 681, p. 20).—Notes are given on canker, mildew, gumming, and numerous insect enemies, with suggestions for their suppression.

Canker—an enemy of the apple, F. H. HALL and W. PADDOCK (*New York State Sta. Bul. 163*, popular ed., pp. 6, pls. 2).—A popular edition of Bulletin 163 of the station (see p. 59).

Diseases of the olive, L. NAVARRO (*Bol. Agr. Min. é Ind. [México]*, 9 (1899), No. 2, pp. 3-115, pls. 12).—This article is in the nature of a general treatise on olive diseases. The diseases of the olive are considered under the following five heads: Influences of the soil, influences of the atmosphere, diseases caused by vegetable parasites, injuries caused by insects, and diseases produced by faulty systems of cultivation.

Fumagine and its treatment, L. DEGRULY (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 6, pp. 165, 168).—Notes are given on fumagine, or sooty mold, occurring on the foliage of the grapes. As the fungus follows attacks of plant lice, the use of

insecticides is advised, the petroleum soap or similar mixtures being recommended. Another formula highly commended is water 100 liters, quicklime 20 kg., and heavy coal oil 8 kg. Winter washes are also advised.

Fungi occurring in the greenhouses of the Berlin Botanic Gardens, P. HENKINGS (*Verhandl. Bot. Ver. Brandenburg*, 40 (1898), p. 109; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 20, pp. 687-689).—An extensive list of fungi and their host plants is given.

The nematode and ammonia salts, C. SCHREIBER (*Rev. Gén. Agron. Lorrain*, 9 (1900), No. 3, pp. 97-102).—This is an account of experiments during 1897, 1898, and 1899 on the use of ammonia salts to destroy nematodes in the soil. Ammonium chlorid and nitrate proved effective for this purpose.

Notes on Bordeaux mixture (*Wiener Illus. Gart. Ztg.*, 24 (1900), No. 1, pp. 13-15).

Potassium permanganate as a fungicide, A. CHEVALLIER (*Prog. Agr. et Vit. (Éd. L'Est.)*, 21 (1900), No. 4, pp. 113, 114).—Potassium permanganate 100 gm., soap 200, and water 100 liters, is said to make a convenient and efficient fungicide for combating black rot and grape mildew.

On the use of calcium carbide as a fungicide, F. GALLET (*Prog. Agr. et Vit. (Éd. L'Est.)*, 21 (1900), No. 4, pp. 126, 127).—Notes the successful use of this substance for the prevention of oidium.

ENTOMOLOGY.

Insect notes for 1899, A. L. QUAINANCE (*Georgia Sta. Rpt. 1899*, pp. 141-145).—Some experiments were conducted in the destruction of *Aphis mali*. A 10 per cent mechanical mixture of kerosene and water killed 50 per cent and a 15 per cent mixture killed 90 per cent of the insects without injury to the trees, while a 20 per cent mechanical mixture killed 92 per cent of the insects, but killed the tree.

Rose Leaf, 1 part to 48 parts of water, killed 98 per cent of the insects. Nikoteen in the same proportion killed from 99 to 100 per cent of the insects, while whale-oil soap, 1 lb. to 6 gal. of water, killed 96 per cent of the insects. These 3 remedies caused no injuries to the trees. Rose Leaf proved almost as effective as Nikoteen, and is much cheaper.

The harlequin cabbage bug (*Murgantia histrionica*) was unusually abundant during the year. A 10 per cent mechanical mixture of kerosene and water killed about 15 per cent of this insect, a 15 per cent mixture killed from 35 to 40 per cent, while a 20 per cent mixture killed about 85 per cent of the bugs, but the latter mixture injured the plants considerably. Nikoteen, 1 part to 32 parts of water, killed about 45 per cent of the insects, and Rose Leaf, 1 part to 32 parts of water, killed none of the insects, although it seemed to act as a repellent.

The author states that despite the severity of the winter of 1898-99, injurious insects caused more than the usual amount of damage throughout the State during the year.

The latter part of the report is a reprint of an article already noted (*E. S. R.*, 11, p. 952).

The peach-tree borer, M. V. SLINGERLAND (*New York Cornell Sta. Bul.* 176, pp. 155-233, figs. 16; *abridged ed.*, pp. 16, figs. 12).—The chief purpose of this bulletin is to present the results of an extended series of experiments with various remedies for the destruction of the peach-tree borer. Besides the discussion of remedies, however, the author presents an account of the habits and life history of the insect, so that the bulletin is considered a sort of compendium of knowledge concerning the peach-tree borer.

The insect lives only a short time in the adult stage and the larvæ are not known to leave the peach tree during their development. The distribution of this insect is, therefore, brought about for the most part by means of infested nursery stock. The author describes the appearance of infested trees, with an account of the gummy exudations.

The insect is probably single brooded everywhere in the United States. In New York the moths appear from June until September. The eggs are laid within a few hours after emerging, on the trunks of trees from 6 to 18 in. from the ground. They hatch in about a week and the young larvæ immediately make their way into the bark. At the beginning of winter the larva prepares for hibernation, either in its burrow or in a thin case on the surface of the bark near the soil. The larvæ begin spring feeding about May 1, and most of them become full grown by June. The author presents an account of the natural enemies of the peach borer, of which one species (*Ephialtes irritator*) was bred by him for the first time.

The author's experiments with remedies against the peach borer extended over a period of about 4 years. An orchard of nearly 400 peach trees of 5 varieties was planted near the insectary for experimental purposes. The author considers the following substances injurious to the trees, and therefore dangerous: Paris green and glue, Raupenleim, Dendrolene, white paint, white paint and Paris green, and printer's ink.

Among effective remedies the following are mentioned: Hale's wash (2 applications), mounding, tarred paper, tobacco stems, gas tar, and digging out. In general it may be stated that remedies against the peach borer are not very successful.

Experiments in growing tansy about peach trees showed that this plant had very slight effect in repelling the borer, but tobacco stems tied about the base of the tree had a noticeable effect. In experiments with the mounding method the soil was usually heaped up to a height of from 6 to 10 in. about the base of the trees. The results indicate that from one-half to seven-tenths of the borers were kept out by this method. In experiments with tarred paper, which was wrapped about the base of the tree, the results indicate that from one-half to seven-eighths of the borers were kept out. It is suggested that probably ordinary paper if carefully applied would prove as effective

as tarred paper. Quite extensive experiments were carried on with wire cages placed about the trees, and it was found that although this method seemed promising from a theoretical standpoint, it proved useless in its practical application. An asafetida and aloes wash was applied to some of the trees for the purpose of determining whether offensive-smelling substances had any effect in deterring the adult insects from laying their eggs upon the trees. The results were negative. Various soap washes, whitewash, and lime-sulphur-salt wash proved to be practically ineffective, as did also hydraulic cement wash. The Paris green and glue wash killed the trees within a few weeks. With regard to the digging-out method, the author states that this is the "only thoroughly successful and safe way of killing the peach-tree borer." He recommends, however, that it be combined with one or another of the methods classified as effective, the particular combination to be made depending on the special circumstances of each case.

An extended bibliography is given of the peach-tree borer from 1749 to the present time.

Preliminary report on the insect enemies of forests in the Northwest, A. D. HOPKINS (*U. S. Dept. Agr., Division of Entomology Bul. 21, n. ser., pp. 27*).—This preliminary bulletin contains a detailed itinerary of a trip by the author through the Northwest and a general account of observations made upon this trip. Especial attention was given to the study of the Scolytid enemies of forests of the Northwest. Among the trees of which the insect enemies were studied, the following may be mentioned: Redwood, western yellow pine, sugar pine, silver pine, red fir, tideland spruce, red cedar, western hemlock, lowland fir, noble fir, and western larch.

Popular notes are given on the influence of farming methods and lumbering methods upon forests and upon the relation of forest fires to depredations by insects. Brief notes are also presented upon the relation of insect enemies of trees to forest fires, the relation of the diseases of trees to insect enemies, and the interrelations of forest fires, insects, and fungus diseases.

Among forest insects of the Northwest which are considered of the greatest economic importance, the following may be mentioned: *Dendroctonus brevicornis*, *D. similis*, *Scolytus praeceps*, *Melanophila drummondi*, and *Neophasia menapia*.

Paris green for the codling moth, C. W. WOODWORTH and G. E. COLBY (*California Sta. Bul. 126, pp. 40, figs. 2*).—During the past 3 or 4 years complaints have been made of the uncertain results obtained from spraying with Paris green. A circular letter was sent to entomologists and editors of agricultural newspapers for the purpose of obtaining statistics upon the question of the quality of Paris green. The answers to this circular letter indicated that in some cases

good and rather uniform results have been obtained by the use of Paris green, while in an equally large number of cases the Paris green was found to be unreliable.

The author recognizes 3 classes of unsatisfactory Paris green—bogus, adulterated, and low grade. In bogus Paris green, substances are substituted for the copper and arsenic of the ordinary Paris green. In adulterated Paris green, white powders, such as gypsum or flour, are added to increase its weight. In the low-grade Paris green there is a low percentage of arsenious oxid in combination, and the requisite percentage of arsenic is secured by the addition of free or soluble arsenious oxid. White arsenic has long been known to be injurious to foliage. The chief feature of Paris green which has made it a standard insecticide is its insolubility, and the addition of free arsenious oxid renders the substance dangerous and worthless as an insecticide. Two forms of poisoning from this substance may be recognized—the acute and chronic. In acute poisoning the leaves show a blackening within 24 hours after the application of the insecticide. In chronic poisoning the leaves become prematurely yellow and drop off within 2 or 3 weeks after the application is made.

A sample of Paris green manufactured in New York City, upon analysis, was found to contain 23.6 per cent of its weight of free arsenious oxid which was soluble in water. Another sample sent to the station contained 29.4 per cent of soluble arsenious oxid. Such grades of Paris green must, of course, be condemned, as they would cause excessive injury to the foliage of fruit trees. A sample of barium arsenite which was analyzed at the station contained 27.64 per cent of free arsenious oxid. One sample of "pink arsenoid," or lead arsenite, contained only 3.24 per cent of free arsenious oxid, while the content of combined arsenious oxid was 40.02 per cent. This sample would not be dangerous to foliage and could be recommended. A sample of copper arsenite contained 7.82 per cent of arsenious oxid, and is, therefore, to be considered as dangerous. A sample of proprietary arsenical spray known as Paragrene was examined under the microscope. It was seen that the sample contained a considerable quantity of gypsum and also crystals of white arsenic. An analysis disclosed the fact that the sample contained 23.08 per cent of free arsenious oxid, and was, therefore, dangerous.

Considerable quantities of lime have been added to the water in which Paris green is mixed in order to render insoluble the free arsenic or other soluble arsenites which are present in Paris green. This method is unsuccessful, however, in cases where the quantity of free arsenic is large.

Several tests may be applied for the purpose of determining the purity of Paris green. Paris green dissolves freely in ammonia, while the majority of substances which have been used for adulterating

it are insoluble in ammonia. This test is valuable, but can not be depended upon in all cases. If a small quantity of the Paris green be placed upon a glass slide and the glass jarred so as to cause the Paris green to slide down the surface of the glass, a bright green track will be left behind if the sample is pure, whereas the track will be white or pale green in case it is impure. The most satisfactory test, however, is the microscopic one. Under the microscope Paris green appears in the form of clean round masses. In impure samples one readily observes in addition to these regular spheres quantities of material of irregular crystalline shape, usually of paler color.

In New York, Louisiana, Texas, and Oregon laws have been enacted requiring Paris green to contain 50 per cent of arsenious oxid. A great defect of these laws is that no attempt is made to distinguish between soluble and insoluble arsenious oxid. A very low grade of Paris green may, therefore, be made to contain a sufficient quantity of arsenic by simply adding arsenious oxid, which is cheaper than Paris green. The standard which has been adopted by the station makes the following requirements: "(1) The sample will be expected to contain, as seen under the microscope, only a trace of foreign matter; (2) the total arsenious oxid shall exceed 50 per cent; (3) the samples shall contain practically no free arsenic or other soluble arsenical compound."

Paris green has proved a satisfactory insecticide against the codling moth when a standard quality is used. The substance has, however, become so unreliable that it seems advisable in the opinion of the author to use some substitute. Arsenite of copper has been used in various localities with considerable success. Barium arsenite was found unsatisfactory, being easily soluble and injurious to the foliage. London purple is the oldest substitute for Paris green, but it often contains considerable free arsenic so as to make it injurious to the foliage. Arsenite of lime has been used in several States with good results. Arsenite and arsenate of lead have been used by the Gypsy Moth Commission as a substitute for Paris green. The arsenate of lead is decidedly the better substance for the gypsy moth and is perhaps to be preferred. Practical directions are given for preparing arsenate of lead, arsenic and lime, and arsenic, soda, and lime.

The author gives a brief discussion of various other methods for fighting the codling moth, among which mention may be made of the band treatment, the destruction of windfall apples, destruction of the codling moth in storage houses, the use of traps for the destruction of the moth, scraping the bark, and the application of winter sprays. Attention is called to the fact that one application of an insecticide is not sufficient. The spraying should be repeated during the summer at intervals of 3 or 4 weeks. It is necessary to take account of differences in the habits of the moth in different localities and during

different seasons in the same locality. The first application in most localities should be made soon after the flowering period, and an effort should be made to wet every part of the plant, since the eggs are deposited indiscriminately on the leaves or upon the young fruit.

Report of analyses of Paris green and other insecticides, L. L. VAN SLYKE (*New York State Sta. Bul.* 165, pp. 221-232).—On account of frequent complaints of the inefficiency of Paris green, the station undertook a chemical investigation of this and other insecticides. Tables are given showing the percentage composition of chemically pure Paris green or copper aceto-arsenite.

In 24 samples of Paris green which were analyzed, the quantity of arsenious oxid varied from 55.34 to 60.16 per cent and averaged 56.48 per cent. The amount of copper oxid in these samples varied from 27.7 to 30.9 per cent, and averaged 29.97 per cent. In pure Paris green, the ratio of arsenious oxid to copper oxid should be 1.87 : 1. In the samples of Paris green which were analyzed, this ratio varied from 1.82 to 2.17 : 1, and averaged 1.88 : 1. The ammonia test indicated the samples to be for the most part free from white arsenic. In all samples the amount of arsenious oxid exceeded the legal requirements. The only adulterant which was found was white arsenic, and this in only 2 cases.

Brief notes are given on analyses made of the following insecticides: Paragrene, Black Death, Slug Shot, London purple, Laurel Green, Smith's Electric Vermin Exterminator, and Bug Death. In the New York law regarding Paris green there is nothing to prevent the addition of any quantity of white arsenic to Paris green. This is considered a decided defect in the law, but from the samples which were analyzed it would appear that it has not been taken advantage of to any considerable extent. The text of the New York law is appended to the bulletin.

The queen bee, A. GALE (*Agr. Gaz. New South Wales*, 11 (1900), Nos. 1, pp. 28-31; 2, pp. 127-130).—Popular notes on the life history and habits of the queen bee.

Care of bees in February, L. WOLFF (*Deut. Landw. Presse*, 27 (1900), No. 9, p. 84).—On account of the small honey flow during the previous season, spring feeding is recommended.

The histolysis of the adipose body in the bee, L. TERRE (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 7, pp. 160-162).—In young larvæ of bees the adipose body consists of a number of more or less rounded cells inclosing large, clear vacuoles. The nucleus of these cells is conspicuous and sharply outlined. The histolysis of this body takes place by a sort of digestion and does not depend upon leucocyte phagocytosis.

The principal household insects of the United States, L. O. HOWARD, C. L. MARLATT, and F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul.* 4, n. s., rev. ed., pp. 131, figs. 64).—This is a reprint of Bulletin 4 of this Division with slight changes (*E. S. R.*, 9, pp. 62-66).

Notes on the part played by insects as carriers of infection, P. SONSINO (*British Med. Jour.*, 1900, No. 2041, pp. 328, 329).—This paper reports a study on the

life history of *Filaria bancrofti* in the body of the mosquito. The *Filaria* was found infesting *Culex pipiens* and *C. ciliaris*.

A novel trap for cockroaches (*Sci. Amer. Sup.*, 49 (1900), No. 1255, p. 20125, figs. 3; from *La Nature*).—A description of a box trap which is said to catch both young and adult cockroaches.

How to distinguish the different mosquitoes of North America, L. O. HOWARD and D. W. COQUILLETT (*U. S. Dept. Agr., Division of Entomology Circ. 40, 2. ser.*, pp. 7, figs. 3).—A synoptic table for the identification of North American species of *Anopheles*, *Culex*, *Psorophora*, *Megarhinus*, and *Aedes*.

Insect bites and the effects thereof, C. P. LOUNSBURY (*Canad. Ent.*, 32 (1900), No. 1, pp. 17-24).—The author discusses at some length the reported cases of injurious effects from the bite of *Argas persicus*. The author believes that *A. persicus*, *A. columbae*, *A. americanus*, and *A. reflexus* probably represent only 1 species. The bite of this tick can hardly be dangerous except under peculiar conditions, but there is always the possibility of the transmission of contagious disease.

Notes are given on bites caused by *Onithodoros savignyi*.

Apple insects of Maine, F. L. HARVEY and W. M. MUNSON (*Maine Sta. Bul.* 56, pp. 105-144, pls. 8).—This bulletin contains a description and an account of the life history, the vulnerable points, and remedies for the following insects which are injurious to the apple: *Anisopteryx pometaria*, *Aphis mali*, *Bucculatrix pomifoliella*, *Cacæcia rosana*, *Carpocapsa pomonella*, *Chrysobothris femorata*, *Clisiocampa americana*, *C. disstria*, *Conotrachelus nemophar*, *Hyphantria cunea*, *Hybernina tillaria*, *Mytilaspis pomorum*, *Edemasia concinna*, *Platysmia cecropia*, *Saperda candida*, *Schizoneura lanigera*, *Terus minuta*, *Tnetocera ocellana*, *Trypeta pomonella*, *Xyleborus pyri*, and *Notolophilus leucostigma*.

Reports on injurious insects in Finland—I-IV, E. REUTER (*Helsingfors*, 1895-1899).

Some common Florida scales, H. A. GOSSARD (*Florida Sta. Bul.* 51, pp. 105-128, figs. 8).—This bulletin contains notes on the appearance, habits, life history, natural enemies, artificial remedies, and host plants of the following insects: *Mytilaspis citricola*, *M. gloverii*, *Lecanium hesperidum*, *L. oleæ*, *L. hemisphaericum*, *Ceroplastes floridensis*, *C. cirripediformis*, and *Dactylopius citri*.

General observations are made on the advisability of spraying at the proper time and in the proper manner. Brief notes are given on the use of kerosene, resin wash, and whale-oil soap.

Notes on Australian Coccidæ, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 11 (1900), No. 2, pp. 99-107, pl. 1).—Notes on the life history and economic relationship of the following species of the genus *Eriococcus*: *E. araucariæ*, *E. araucariæ* var. *minor*, *E. capitata*, *E. burri*, *E. conspersus*, *E. coriaceus*, *E. confusus*, *E. eucalypti*, *E. leptospermi*, *E. multispinosus*, *E. paradoxus*, *E. spiniger*, *E. tepperi*, and *E. turgipes*.

Inspection of American fruit for San José scale in Hamburg, J. KOCHS (*Deut. Landw. Presse*, 27 (1900), No. 9, p. 84, figs. 2).—Brief popular notes.

Truth about the San José scale, J. P. SMITH (*Amer. Agr.*, 65 (1900), No. 1, pp. 2, 8).—Popular notes on the efficiency of various remedies against this insect.

German echoes of the commercial inspection (*Sci. Amer. Sup.*, 49 (1900), No. 1259, pp. 20189, 20190).—Brief notes on the dangers from San José scale in Germany.

The codling moth (*Jour. Agr. and Ind. South Australia*, 3 (1900), No. 6, pp. 507-509).—Report of a special committee concerning the extent of infestation of South Australia by the codling moth and means for its eradication.

The strawberry sawfly and the gooseberry fruit worm, J. P. CHAPPAIS (*Nat. Canad.*, 27 (1900), No. 2, pp. 17-20).—Brief notes on *Emphytus maculatus* and *Dakruma convolutella*.

Fruit fly notes, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 1, pp. 43-45).—Experiments by the author indicate that the insect probably does not hibernate in the adult stage, but as pupæ. The remedies recommended are the destruction of infested windfalls, covering the trees with nets, and allowing fowls to run in the orchard.

Notes on some micro-lepidoptera, SCHÜTZE (*Stettin. Ent. Ztg.*, 60 (1899), No. 7-8, pp. 163-179).—Notes on a species of *Tinea*, *Prays*, *Argyresthia*, *Galechia*, and *Brachmia*.

On *Ægaleus bechuana*, a new species of Cimicidæ reported to injure coffee berries in British Central Africa, G. W. KIRKALDY (*Entomologist*, 33 (1900), No. 442, pp. 77, 78).—Specimens of this insect were sent to the author from Central Africa by Mr. Green with the statement that they were puncturing coffee berries. The species is described as new.

Fruit-feeding habit of the cotton worm moth, C. E. BROWN (*Bul. Wisconsin Nat. Hist. Soc.*, n. ser., 1 (1900), No. 1, pp. 67).—*Aletia argillacea* is reported as feeding upon grapes in Milwaukee.

Caterpillars and maple sugar (*Nat. Canad.*, 27 (1900), No. 2, pp. 26-28).—A brief account of the effects of depredation by *Utiocampa distria* upon the quality of maple sugar.

A gall-making *Coleophora*, WALSINGHAM (*Ent. Mo. Mag.*, 2. ser., 11 (1900), No. 123, pp. 59, 60).—*C. stefanii* is reported as producing galls on the stems of *Atriplex halimus*. The author gives brief notes on the appearance and habits of this insect.

Swarming of the milkweed butterfly (*Danais archippus*), P. H. DERNEHL (*Bul. Wisconsin Nat. Hist. Soc.*, n. ser., 1 (1900), No. 1, pp. 64, 65).

Gadfly and botfly, C. J. VALENTINE (*Jour. Agr. and Ind. South Australia*, 3 (1900), No. 6, pp. 516, 517).—Notes on the life history of *Gastrophilus equi*.

The breathing of *Hydrophilus*, H. J. KOLBE (*Illus. Ztschr. Ent.*, 5 (1900), No. 3, pp. 38, 39).—The author's observations were made on *Hydrophilus piceus*. The beetles were observed to come frequently to the surface of the water to obtain air.

Lethrus apterus, J. TARNANI (*Illus. Ztschr. Ent.*, 5 (1900), No. 4, pp. 49, 50).—Brief notes on the habits, life history, and food plants of this insect, which is especially injurious to grape vines.

On the larvæ, habits, and structure of *Lithocolletis concomitella* and its nearest allies, J. H. WOOD (*Ent. Mo. Mag.*, 2. ser., 11 (1900), No. 122, pp. 30-34).—A description of the larvæ, with notes on the mining habits of this and other species in the leaves of *Prunus avium*, *Pyrus aucuparia*, etc.

FOODS—ANIMAL PRODUCTION.

Cereal breakfast foods, C. D. WOODS and L. H. MERRILL (*Maine Sta. Bul.* 55, pp. 93-106).—The authors report the analysis of a considerable number of commercial cereal breakfast foods. These include 4 corn preparations, 3 uncooked oatmeals, 11 cooked oat preparations, 16 wheat preparations, 3 gluten preparations, and 4 miscellaneous articles.

The different articles and classes are discussed at some length. The authors note that many of these cereal foods have been thoroughly cooked during the process of manufacture and then dried, so they will keep indefinitely.

"The process of manufacture is hygienic and cleanly and will bear the closest inspection. Starting from the elevator, the goods are cleaned, milled, cooked, evaporated, and packed by machinery. It is very gratifying to find that this class of goods is free from adulteration and careless preparation. . . .

"Protein is furnished more cheaply by oat preparations than by those of corn or wheat. The oats also supply fat 10 times as cheaply as the corn products and 5 times as cheaply as the wheat foods. The carbohydrates are supplied most economically by the corn preparations, oats ranking second. In fuel value, oats again rank first.

"If wheat flour be included in the comparison, it will be found to be the cheapest source of protein and carbohydrates. With the exception of one sample of rolled oats, it also leads in fuel value."

Commercial feeding stuffs in the Connecticut market, E. H. JENKINS, A. L. WINTON, ET AL. (*Connecticut State Sta. Bul.* 130, pp. 40).—Commercial feeding stuffs and their uses are briefly discussed, and the analyses of a large number of such materials reported. These were made in compliance with the Connecticut law regulating the sale of these goods and include cotton-seed meal, linseed meal, ground wheat, bran, middlings, mixed wheat feed, corn meal, gluten meal and gluten feeds, hominy chop, ground oats, provender, corn and oat feeds, oat feeds, corn, oats, and barley, rye bran and rye feed, malt hulls, starch feeds, Champion Bell Fodder, H. O. dairy feed, H. O. horse feed, H. O. poultry feed, American Cereal Company's Quaker Dairy Feed and Poultry Food, Blatchford's Calf Meal, Pioneer Clover Meal, carob bean, carob bean pods, carob beans and pods, Barnes's Horse and Stock Feed, Bowker's Animal Meal, and Lederer's Poultry Food.

"No cases of actual adulteration have been found among the samples examined. A considerable number of these 'feeds,' notably most of the so-called 'oat feeds,' are, however, of such inferior quality that they can not be used to any profit.

"It appears that the three most concentrated feeds, the three which, pound for pound, will go farther in 'balancing' or piecing out the ration made from home-grown feed, viz, cotton seed, linseed, and Atlantic gluten meal are the most costly. This is as it should be. Yet of these, the one which contains the most protein, 'Atlantic gluten meal,' is the cheapest. It does not follow that it should be bought to the exclusion of the others. Linseed meal, though a very expensive feed, is greatly relished by cattle, flavors the food and is generally regarded as an excellent thing to keep cows 'in condition.' But evidently the wise feeder will endeavor to use the cheaper forms of protein as far as possible.

"An examination of the prices and analyses of the feeds given in the table also shows that the market prices bear very little if any relation to their feeding value. That is, 'feed' costs from \$17 to \$20 per ton at retail, whether it is concentrated, rich in protein, and well suited to supplement the home-grown feed, or whether it is a starchy food and of much less value in compounding suitable cattle rations. In this condition of the market, special care in the purchase of feeds and some knowledge of their chemical composition will be found highly advantageous in keeping the cost of milk production down to a point which will admit of profit in the business."

Analyses of feeding stuffs, H. A. HUSTON and A. H. BRYAN (*Indiana Sta. Rpt.* 1899, pp. 67-72).—Analyses are reported of large green okra seed, buckwheat, Rauh's stock food, distillery slop, and a number of samples of mangel-wurzels and sugar beets. The protein con-

tent of 2 samples of corn was also studied. Several of the analyses follow:

Composition of okra seed, buckwheat, and distillery slop.

Analyses of feeding stuffs, F. W. WOLL (*Wisconsin Sta. Rpt. 1899, pp. 271-274*).—The author reports the composition of the following feeding stuffs: Blood-molasses feed (sample manufactured in Denmark), flour middlings, bibra cake (from the Hawaiian Islands), condimental food, broom-corn millet seed, yellow corn germ, white corn germ, wild rice, *Zizania aquatica*, parched and sun dried. A number of these are quoted in the following table:

Composition of a number of feeding stuffs.

	Moisture.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.	Ash.

a Containing 0.14 per cent amid nitrogen. *b* Containing 0.8 per cent amid nitrogen.

“[The blood molasses] shows a medium content of protein. A good share of this component is most likely in the form of amids and lower nitrogenous compounds, which possesses an inferior feeding value as compared with protein substances proper. The feed is, however, made up of foods of high nutritive value. . . .

“Bibra cake is one of the cattle foods used in the Hawaiian Islands. Its price is given as \$40 per ton. A comparison with our standard protein foods will show that it is much lower in protein than these and its crude fiber content is rather high, making it a less valuable feed than, for example, any of our oil meals. . . .

“The 2 samples of wild rice were obtained from Lac Courte Oreille Indian Reservation in Wisconsin. . . . Wild rice grows to a large extent in lakes and streams in the northern part of our State, and is used extensively by the Indians as a cereal crop. We notice that it ranks higher than any of our leading cereals in chemical composition, its contents of protein and nitrogen-free extract (mainly starch) being greater than those found in any of these. So far as can be judged from chemical analysis alone, wild rice has, therefore, a high food value.”

Winter v. spring bran, W. FREAR and W. A. HUTCHISON (*Pennsylvania Sta. Bul. 48, pp. 8*).—Analyses are reported of 10 samples of bran from winter wheat and a like number of samples from spring wheat.

On the basis of these analyses, the 2 sorts of bran are compared, other American work on the subject being quoted. The authors' conclusions follow:

"On the average, despite the higher market price, winter bran furnishes a smaller quantity of nitrogenous nutrients to the animal because of its inferiority in composition, and, possibly, of its lower digestibility. The composition of these brans is not at all constant in regard to the more important constituent, protein. In the case of winter bran, the best contained one-tenth more than the poorest; in the case of spring bran, the best contained over one-fifth more than the poorest. In other words, 9 tons of the best winter bran would furnish as much protein as 10 tons of the poorest; while among spring brans, 8 tons of the best would supply as much protein as 10 tons of the poorest.

"As represented by these analyses, Maine and Massachusetts, maintaining an official control over the sale of cattle foods, secure a somewhat less variable article, and, especially in case of winter bran, a better average article than is obtained in Pennsylvania. The number of analyses represents too small a part of the trade in these foods to justify sweeping conclusions. By reason of its great variability in food value as indicated by analysis, bran should not be bought in large quantities except under guaranty of composition."

Contribution to the study of the energy content of human urine, M. TANGL (*Arch. Anat. u. Physiol., Physiol. Abt.*, 1899, *Sup. pt. 1*, pp. 251-266).—The author reports a number of experiments on the nitrogen and carbon content and fuel value of human urine when different diets were consumed. The balance of income and outgo of nitrogen was also determined. The principal conclusions follow:

The ratio of the heat of combustion to nitrogen and that of carbon to nitrogen in the urine is much greater when the diet consists largely of carbohydrates than when it consists principally of fat. In other words, these ratios can be markedly influenced by diet. Under the conditions of the author's investigations, these quotients varied correspondingly. The 2 ratios did not change when work was performed. This is in harmony with the results of experiments in which the respiration quotient was determined and the theory of Zuntz and his followers, that during rest and work the same proportion of nutrients is metabolized—that is, the proportion of those nutrient materials which the organism has available in sufficient quantity. The article contains a bibliography of the subject.

Sheep feeding, R. T. SHAW (*Montana Sta. Bul. 21*, pp. 13).—The author discusses the possibility of profitably fattening lambs in Montana instead of shipping them for this purpose to other regions, and believes it is possible to raise an abundance of suitable forage crops for the purpose. The comparative value of alfalfa, red clover, and alsike hay was tested with 3 lots, each containing at the beginning of the test 16 grade Merino lambs showing Cotswold blood, weighing on an average $42\frac{1}{5}$ lbs. All the lambs were fed pulped turnips and a grain ration, which at first consisted of $1\frac{1}{4}$ lbs. of oats per head daily. The amount

of oats was afterwards increased and a little flaxseed and cracked peas (pea screenings) added. In addition lot 1 was fed alsike hay; lot 2, red clover hay; and lot 3, alfalfa hay. Both the alfalfa and red clover hay were from second cuttings, and the alsike from the first cutting. One of the lambs in lot 3 was dropped on account of bloating.

The test proper began January 2, 1898, and continued 84 days.

The financial statement is based on oats at \$1, pea screenings 50 cts., flaxseed \$1.50, and roots at 9 cts. per hundredweight, and hay at \$6 per ton. The following table summarizes the results of the tests:

Alfalfa, red clover, and alsike hay for lambs.

	Feed consumed.					Total gain.	Feed consumed per pound of gain.		Cost per pound of gain.
	Hay.	Turnips	Oats.	Flax-seed.	Peas.		Hay.	Grain.	
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Cents.</i>
Lot 1 (16 lambs; alsike hay)	2,562	1,340	780	42	241	405	6.32	2.62	4.51
Lot 2 (16 lambs; red clover hay)	2,588	1,340	780	42	241	402	6.43	2.64	4.62
Lot 3 (15 lambs; alfalfa hay)	2,484	1,340	780	42	241	377	6.58	2.81	4.82

"(1) With the great abundance of leguminous crops and the ease with which they can be produced in Montana, we believe it would be of great advantage to the Montana farmer to fatten at least a few sheep each winter season.

"(2) Under the very favorable climatic conditions the amount of food required and cost of production per pound gain are relatively small.

"(3) Careful comparison has shown that alsike, the red clovers, and alfalfa have given results for feeding value in the order named.

"(4) Food materials which would otherwise be wasted can be utilized with profit where sheep are kept on the average farm."

Sheep-feeding experiments, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 61, pp. 67-75*).—The usual practice in West Virginia, according to the authors, is to market in the fall lambs raised for mutton. The possibility of profitable winter fattening of lambs was tested in 2 trials. The first trial was made with 2 lots of Southdown and Shropshire grade lambs and "natives, such as could be found in any section of the State," and 1 lot of native yearling wethers. Lot 1 (8 ewe lambs and 2 wethers) and lot 3 (5 yearling wethers) were fed a grain ration consisting of equal parts of linseed meal, wheat bran, and hominy feed. Lot 2 (8 ewe lambs and 2 wethers) was fed whole corn. All 3 lots were fed, *ad libitum*, mixed clover and timothy hay which was not thought to be of extra quality. The test covered 8 weeks. The average gain per lamb in the different lots was 14.5, 15.4, and 8.8 lbs., respectively; and the cost of feed per pound of gain was 4.9, 3.7, and 10.7 cts. The wether lambs gained on an average 18.4 lbs., while the ewe lambs gained only 14.1 lbs. The value of the manure is taken into account.

"Although definite conclusions should not be drawn from one experiment, yet this feeding test indicates that lambs can be fattened more profitably than yearling wethers, and that under favorable conditions it may be better for farmers who have an abundance of coarse fodder to feed their lambs heavily for 8 or 10 weeks, instead of selling them at the usual time in the fall. It also indicates that forage and grain produced upon the farm may be sold at home for a higher price than the market offers."

A second test in the fall of 1898, with 60 lambs, was discontinued on account of many of the lambs being seriously affected with an internal parasite. The indications were that cowpea hay was superior to timothy hay, although the gains were unsatisfactory in all of the lots.

Feeding ground corn v. ground peas to lambs before and after weaning. W. L. CARLYLE (*Wisconsin Sta. Rpt. 1899, pp. 44-51, figs. 2*).—For the past 10 years the station has studied the feeding value of different grains for lambs before and after weaning (E. S. R., 11, p. 567). In the present test, coarsely ground corn and ground peas were tested with 2 lots of 17 lambs each, before and after weaning. The dams (11 Shropshire ewes per lot) were with the lambs until weaned. The lambs and ewes were pastured on blue grass during the day and housed during the night. Lot 1 was fed ground corn and lot 2 ground peas. Until weaning the grain was fed *ad libitum*; after weaning it was fed at the rate of about $\frac{1}{2}$ lb. per day. The ewes were not fed grain. The test began May 24, 1898, and was divided into 2 periods of 10 weeks each, the lambs being weaned at the close of the first period. In discussing the financial returns, corn is rated at 30 and peas at 45 cts. per bushel. Previous to weaning, the average daily gain of lot 1 was 8.7 lbs., and of lot 2, 8.9 lbs., the grain required per pound of gain with the 2 lots being 0.883 lb. and 0.889 lb. After weaning, the average daily gain of the 2 lots was 6 and 5.1 lbs., respectively; the corresponding amounts of grain required per pound of gain being 2.11 and 2.41 lbs. During the whole test the cost of a pound of gain with lot 1 was 0.752 ct., and with lot 2, 1.085 cts. "Ground corn is a better feed than ground peas, pound for pound, when fed to young lambs, and is much the more economical feed when the average ruling prices of the 2 grains are considered."

At the close of the test, the carcasses of 2 lambs from each lot were compared. "The proportion of lean to fat and the character of the fat as to solidity, color, etc., appeared to be exactly the same in the carcasses of lambs from both the lots."

In connection with the above test, the comparative effect upon the ewe of nursing single and twin lambs, as well as the gains made by single and twin lambs and the comparative gains made by ewe and wether lambs, were also studied.

"A ewe can raise twins without losing any more weight than when raising a single lamb. The ewes losing the most flesh while suckling lambs are not necessarily the best mothers. Wether lambs gain more rapidly than the ewe lambs while nursing. Twin lambs nursing one mother gain as rapidly as when there is but one lamb nursing."

The influence of manures on the production of mutton, W. SOMERVILLE (*Jour. Bd. Agr. [London], 6 (1899), No. 3, pp. 293-310*).—In continuation of work previously reported (E. S. R., 10, p. 1084), the value of different fertilizers on poor pasture was tested by comparing the yield of hay and the growth made by sheep pastured on plats fertilized with cotton-seed cake, lime, Thomas slag, dissolved bone, and superphosphate, alone and in combination with potash, with lime, and with ammonia. One plat (No. 6) served for purposes of comparison and was not fertilized. The following table summarizes the results obtained in 1899:

Average results of different methods of manuring pasture as shown in 1899 by production of hay and mutton.

Plats.	Treatment.	Hay in excess of amount produced by plat 6.	Mutton in excess of amount produced by plat 6.	Hay consumed per pound of gain in live weight of sheep.	Average live weight of sheep.	Average dressed weight of sheep.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
1	Cotton-seed cake.....	46	139	21.4	115.5	53.5
2	Lime.....	14	4	38.8		
3	Full dressing of slag.....	97	233	20.8	127.0	57.5
4	One-half dressing of slag.....	68	96	30.1	117.5	53.5
5	Superphosphate.....	47	91	27.0	114.0	53.0
6	Nothing.....			35.1		
7	Superphosphate and potash.....	28	117	20.6	120.5	53.5
8	Superphosphate and lime.....	48	119	23.6	122.5	54.5
9	Superphosphate and ammonia.....	54	104	26.7	126.0	57.0
10	Dissolved bone.....	51	104	26.7	122.5	57.0

The effect of the different manures is discussed at some length and the results of this test are compared with those obtained earlier. When slaughtered the sheep were judged by an expert. Those pastured on plat 6 were considered the best mutton. Those on plats 1, 3, and 4 next in order, followed by those on plats 10, 5, 7, 8, and 9, which were much alike. The sheep were said to be much like others slaughtered the same season, which was very dry. They showed a lack of kidney fat and made small gains. In the author's opinion, grazing the sheep is the best method of testing the comparative value of the different fertilizers. However, it should be remembered that after the sheep were taken from the plats there still remained a considerable amount of fodder, the amount varying in the different plats.

"This feed has been utilized by cattle with which the plats were stocked in proportion to apparent requirements, a note being kept of the duration of the respective periods of grazing. The 30½ acres have each autumn maintained 18 breeding cattle for fully 2 months, and that they found enough to eat is proved by the fact that they came off in excellent condition. Allowing 24 cts. per head per week for grazing, the plats are credited with sums varying between \$2.40 (plat 6) and \$4.85 (plat 3) per acre."

Whole corn compared with corn meal for fattening swine, W. A. HENRY (*Wisconsin Sta. Rpt. 1899, pp. 19-24*).—Continuing previous work (E. S. R., 11, p. 571), the comparative value of whole and ground corn was tested with 2 lots of 19 pigs each, containing 9

sows and 10 barrows. Five pigs in each lot were pure-bred Poland China, the others Berkshire-Poland Chinas. These were the same pigs used in the experiment with rape and clover mentioned below. After a preliminary period of 1 week, the test began November 19 and covered 84 days. Lot 1 was fed whole corn and middlings; lot 2, corn meal and middlings. The total weight of lot 1 at the beginning of the test was 3,543 lbs. and of lot 2, 3,538 lbs. During the test lot 1 consumed 7,084 lbs. of shelled corn and 3,542 lbs. of wheat middlings, and gained 2,132 lbs. That is, 4.97 lbs. of corn meal and middlings were required for a pound of gain. Lot 2 consumed 7,196 lbs. of corn meal and 3,598 lbs. of middlings, and gained 2,132 lbs., the grain required per pound of gain being 5.07 lbs. Discussing this test and previous trials, the author says:

“It is evident from our work as conducted to the present time that the gains from grinding corn as a food for swine are not very large in most cases and negative results may be obtained. It is expected that the work will be continued for some time to come or until we shall know more definitely what the real advantages are, if any, of grinding corn for fattening swine.”

Rape v. clover for young pigs, W. L. CARLYLE (*Wisconsin Sta. Rpt. 1899, pp. 25-30, figs. 2*).—The comparative value of rape and clover for young growing pigs was tested with 2 lots, each containing 21 pure-bred and high-grade Berkshires and Poland Chinas, averaging a little over 100 lbs. in weight when the test began. (For earlier work see E. S. R., 11, p. 571.) The 2 lots were fed a grain ration of middlings and corn meal 1:2 mixed with water into a thick slop 12 hours before feeding. In addition lot 1 was fed rape. The pigs were confined by a portable fence, being moved as required. They were somewhat slow in acquiring a taste for the rape, but at the end of a week of the preliminary feeding they ate it greedily. In addition to grain lot 2 was pastured on about 8 acres of second growth clover. The test covered 4 periods of 2 weeks each. During this time the pigs in lot 1 ate the rape from about $\frac{3}{4}$ acre. At the beginning of the test the pigs in the 2 lots weighed 2,139 and 2,138 lbs., respectively. The corresponding average daily gains of the 2 lots during the test were 1.27 and 1.22 lbs. The results are compared with those obtained in previous years. In discussing this year's tests the author remarks that—

“The pigs fed on the rape appeared more paunchy as a whole at the close of the experiment than were those fed on clover, though they were all of the same breeding and very uniform as to conformation when the experiment began.

“Another year's experience in pasturing pigs on rape serves to strengthen the conclusion of last year, viz., that farmers feeding any number of pigs can not provide a better pasture for them than to sow small plats of rape at successive periods about 3 weeks apart during the spring and early summer months to be used for pasturage for their sows and young pigs.”

On the food requirements of the pig for maintenance and for gain, W. DIETRICH, reported by F. W. WOLL (*Wisconsin Sta. Rpt. 1899, pp. 31-43*).—The amount of food required at different weights for maintenance and for growth was tested with 4 pigs weighing about 50 lbs. each at the beginning of the trial. The general plan was to diminish the ration until the smallest quantity which would maintain the pigs at a constant weight was ascertained. Feeding was continued until it was certain that the ration was sufficient for maintenance. The ration was then increased and the pigs fed until they weighed 100 lbs. each, when the amount necessary for maintenance at that weight was determined. In this way the maintenance ration was also determined for pigs at 150 and 200 lbs. live weight.

The pigs used were 2 barrows and 2 sows, all from the same litter, and were a cross between a pure-bred Berkshire sire and a Poland China-Chester White sow. They were 81 days old at the beginning of the trial, which began July 13, 1898, and closed April 1, 1899. It was divided into 4 periods of 56, 58, 71, and 74 days, respectively. During the first period the ration consisted of corn meal and wheat bran, 1:2, mixed with buttermilk and a little water, the nutritive ratio being 1:4. During a part of the time skim milk was used in place of buttermilk. During the second period the ration consisted of corn meal, middlings, and skim milk, 1:1:4, with a little rape in addition. The nutritive ratio was 1:5. During the third period the nutritive ratio was changed to 1:5:7, the food consisting of corn meal, middlings, and skim milk, 1:1:2. During the fourth period the feed was changed to corn meal and middlings, 1:2, the nutritive ratio being 1:6. The pigs did not eat as much after this change as they had done previously and the feed was therefore reduced from the allowance during the third period. The feeding stuffs used were analyzed. "The fifty-pound pigs were each maintained on a ration containing 0.15 lb. of corn meal, 0.15 lb. of middlings, and 1.2 lbs. of skim milk; at 100 lbs. weight it took 0.4 lb. of corn meal, 0.4 lb. of middlings, and 1.6 lbs. of skim milk; at 150 lbs. weight it took 0.8 lb. of corn meal, 0.8 lb. of middlings, and 1.6 lbs. of skim milk; and finally at 200 lbs. the pigs required 0.67 lb. of corn meal and 1.33 lbs. of middlings each for maintenance." The dry matter required daily for maintenance in the 4 periods was 0.37, 0.87, 1.54, and 1.76 lbs., respectively. The dry matter required per pound of gain in the 4 periods was 2.24, 2.08, 3.12, and 3.96 lbs., respectively, and the average daily gain in the 4 periods was 0.93, 1.66, 1.85, and 1.22 lbs. The number of days required for 50 lbs. of gain by the pigs at different weights was also computed. The pigs weighing 50 lbs. required 54 days; at 100 lbs., 30 days; at 150 lbs., 27 days, and at 200 lbs., 41 days.

"We observe that the older the pig grows the greater becomes the [relative amount of food required for maintenance] and the greater the amount of food required to produce 100 lbs. of gain. But considering that the percentage of the food is small in proportion to the total food eaten at the 150-pound stage and that here the pig consumes a large quantity of food per day and makes a large gain, it would seem that the 150-pound pig is the most profitable one to feed. The large percentage of food for maintenance to live weight is counterbalanced by these other facts. This appears all the more evident when we consider what a small quantity of food was consumed per day by the 200-pound pig. When we consider that the 200-pound pig ate only 2.41 lbs. of dry matter per 100 lbs. of live weight and that 36 per cent of this goes to sustain the life of the animal, we can easily see why the daily gain dropped from 1.85 lbs. per day with the 150-pound pig to 1.22 lbs. per day with the 200-pound pig. . . .

"During the maintenance period the pigs did not show much greater signs of hunger than when on full feed, but a few days, when they were given less than maintenance allowance, they appeared to suffer from hunger. They seemed to feel well during the maintenance feeding and would sometimes run about and play like young dogs; when on full feed they were lazy and would lie about in the pen. . . .

"It was noticed that some pigs were slower eaters than others, and this may explain why better results are not obtained when the animals are fed together in large numbers. It was also noticed that the best results were obtained when the pigs were on a feed increased uniformly from day to day."

During all periods of gain the tails were curled. During maintenance periods the tails of the pigs hung straight down. "The curl in the tail appeared and disappeared as the change was made from maintenance to full feed and *vice versa*."

In connection with the above experiment the digestibility of the maintenance ration and the ration for growth was tested with 2 pigs for 2 periods of 3 days each. "It appears that a pig will digest a little more food when on a maintenance ration than when supplied with as much food as will be eaten." These results are compared with those obtained at the Minnesota Station (E. S. R., 4, p. 733).

Nuts as food, C. D. WOODS and L. H. MERRILL (*Maine Sta. Bul.* 54, pp. 71-92).—Statistics of the amount of nuts imported into the United States are quoted and the composition of a number of nuts analyzed at the station reported. These include Brazil nuts (*Bertholletia excelsa*), filberts, hickory nuts, pecans, peanuts, peanut butter, edible acorns called "biotes" (*Quercus emoryi*), acorn meal, acorn bread, beech-nuts, butternuts (*Juglans cinerea*), cocoanut, cocoanut milk, litchi nuts (*Nephelium litchi*), pine nuts (*Pinus monophylla*, *P. edulis*, *P. sabianiana*), and pistachio nuts. The authors also quote a considerable number of American analyses of nuts made by other investigators. The characteristics of the different nuts are discussed as well as their preparation and use as articles of diet.

Analyses of maple sugar, H. A. HUSTON and A. H. BRYAN (*Indiana Sta. Rpt.* 1899, pp. 74, 75).—The composition of 4 samples of maple sugar and a sample of what is known to maple-sugar makers as "niter" or "sugar sand" is reported. The sugar sand had the following percentage composition: Water, 6.11; insoluble matter, 9.13; reducing sugars, 12.74; sucrose, 26.88; calcium, 12.89; malic acid, 20.86; potash, 0.72; protein, 0.40; and magnesium, a trace. According to the authors, this material is sometimes known as "malate of lime." It is suggested that it might be of some value as a source of malic acid.

Liebig Company's extract of meat (*Sci. Siftings*, 17 (1900), No. 343, p. 230).—The food value of this meat extract is discussed and an analysis reported.

Indian edible oils, W. R. DUNSTAN (*Agr. Ledger*, 1899, No. 12, *Veg. Prod. ser. No. 52*, pp. 1-34).—A report on the chemical and physical examination of a large number of vegetable oils used for culinary purposes in India.

State of Michigan Dairy and Food Department Bulletin 55 (pp. 27).—This bulletin contains a discussion of process butter, an article entitled "Method for the detection of process or renovated butter" by W. H. Hess and R. E. Doolittle, a report of the inspections made by the department, a report by the department chemist of the examination of a number of samples of butter, cinnamon, flavoring extracts, ginger, jelly, fruit butter, molasses, mustard, pepper, sirup, and vinegar. An abstract of the Michigan pure-food laws and a number of court decisions under them are also given.

State of Michigan Dairy and Food Department Bulletin 56 (pp. 18).—This bulletin discusses the work of the dairy and food department, reports legal proceedings, dairy inspections, analyses of samples of beans, buckwheat flour, butter, flavoring extracts, ginger, honey, jelly, mustard, peas, pepper, rice, sugar, and wine. The Michigan food laws are noted, together with a digest and rulings.

Character and extent of food and drug adulteration in Massachusetts, and the system of inspection of the State board of health, A. E. LEACH (*Tech. Quart.*, 13 (1900), No. 1, pp. 22-40, figs. 2, pls. 3).—A paper read before the Boston Society of Arts, December, 1899, describing the common forms of adulteration and the methods followed in combating adulteration and sophistication of food and drugs.

Bacteriology applied to the canning and preserving of food products, E. W. DUCKWALL (*Baltimore: The Trade*, 1899, pp. 112, figs. 24).—The major portion of this publication treats of the nature and character of bacteria, including pathogenic species, methods of propagating, kinds commonly found in decomposing fruits and vegetables, methods of studying bacteria, summary of the characteristics of the various organisms found in food products, and the scientific principles involved in canning and preserving.

Chapters are also given on antiseptics and germicides, history of canning, methods of canning corn, peas, tomatoes, tomato products, oysters, meats and fish in general, pickles, kraut, and soup. Some results of sterilizing experiments are included in the work and a chapter given on sterilization in canning.

The food rations in Ladysmith, J. C. DUNLOP (*British Med. Jour.*, 1900, No. 2046, pp. 667, 668).—The food value of the rations issued to the soldiers and other inhabitants of Ladysmith during the latter part of the recent siege is calculated to be 73.4 gm. protein and 1,527 calories per man per day.

The feeding of prisoners, F. HIRSCHFELD (*Ztschr. Diätet. u. Phys. Ther.*, 4 (1900-1901), No. 1, pp. 37-53).—The dietary in a Berlin prison was studied, and in addition 4 nitrogen metabolism experiments were made.

Concerning the metabolism of a vegetarian, T. RUMPF and O. SCHUMM (*Ztschr. Biol.*, 39 (1899), No. 1, pp. 153-158).—The subject of this investigation was a strict vegetarian. During his youth he had eaten eggs, butter, milk, and cheese, but since his eighteenth year vegetable food only. His parents were also vegetarians. During 8 days the amount of food consumed was recorded and the urine and feces were analyzed. The food consisted of Graham bread, apples, dates, Quaker oats, rice, sugar, and walnuts. The diet furnished 73.88 gm. of protein, 28.64 gm. of fat, 698.21 gm. of carbohydrates, and 3,431.92 calories. The daily income of nitrogen was 11.82 gm.; 6.91 gm. was excreted in the urine and 4.01 gm. in the feces. There was, therefore, on an average, a gain of 0.9 gm. per day. The food contained 28.64 gm. of fat, and the feces 7.58. The subject weighed 62.5 kg. at the beginning, and gained 1.7

kg. during the experimental period. In the authors' opinion, the vegetable diet somewhat more than sufficed for maintenance.

Ensilage without pressure, Ross (*Agr. Gaz. New South Wales*, 11 (1900), No. 1, pp. 36, 37).—The author's experience, extending over a number of years, in ensiling maize in stacks without pressure is given. This method of preserving maize is regarded as entirely satisfactory. "The stack is an absolute success except for the slight loss at the top and sides."

The foundation principles in determining feeding standards for farm animals, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, I, No. 10, pp. 344-346; 11, pp. 381, 382).—A general discussion.

Feeding experiments with different quantities of the same foods at the college farm, T. WINTER (*Bd. Agr. [London] Rpt. Distrib. Grants for Agr. Ed. Great Britain*, 1898-99, pp. 48-52).—A feeding experiment conducted at the University College of North Wales with 2 lots of 4 steers each, averaging about 1,100 lbs., is briefly reported. The object was to compare a ration of 3 lbs. of maize meal and 3 lbs. of decorticated cotton-seed cake with one containing 5 lbs. of each of these, feeding pulped Swedish turnips, chaffed hay and straw in addition.

The test began November 29, 1898, and closed February 8, 1899. The steers receiving 6 lbs. of grain made an average daily gain of 1.92 lbs., and those receiving 10 lbs. made an average daily gain of 1.65 lbs. The steers were slaughtered at the close of the test. The average percentage of dressed to live weight in the 2 lots was 53.2 and 55.7 respectively.

Feeding experiments with root crops, L. HELWEG (*Landtmannen*, 10 (1899), Nos. 47, pp. 774-777; 48, pp. 790, 791; 50, pp. 820-824).

Cost of feeding steers, L. McKIM (*Wallace's Farmer*, 25 (1900), No. 15, p. 410).—A general discussion which includes some statistics.

DAIRY FARMING—DAIRYING.

The mammary gland, A. W. BITTING (*Indiana Sta. Rpt.* 1899, pp. 36-43, pls. 5).—An account is given of the anatomy and physiology of the mammary gland and its development in different types of Mammalia, particular attention being paid to the form, structure, and vascular supply of the cow's udder.

"The udder of the cow consists of a variable number of mammary glands, usually 4 that are functional (the quarters) and from 1 to 4 that are rudimentary. They are arranged in pairs, being on opposite sides of the median line of the body, and occupy the inguinal region (groin). . . .

"The shape and size of the organ as a whole differs in the different breeds and in individuals of the same breed. In some breeds the aim has been to develop a large secretory function, and an enormous glandular development has been the result. In other breeds the quality of the milk has been the prime consideration, and the gland is smaller. In the beef breeds the gland is often invaded with fatty tissue and the udder appears large, but the quantity of glandular tissue is small. . . .

"The weight of the dissected udders, as found in our investigations, varied from 2 lbs. and 3 oz. to 41 lbs. and 6 oz. . . .

"A dissection of the udder shows that each half is enveloped in a strong fibrous capsule, and that the fibers intermingle on the inner side and are prolonged upward to act as ligamentous support for the gland. The halves are distinct, as they may be easily separated throughout their inner aspect. The individual glands in each half of the udder are not so distinctly separated. . . .

"The structure of the mammary glands can be studied to advantage by injecting each teat and the arteries and veins with different colored injection masses. Each gland is enveloped in an elastic, fibrous capsule or membrane, to which externally the skin is loosely adherent; internally the fibers intermingle with those of the gland from the opposite side and become prolonged upward as a suspensory ligament. . . .

"Above the teat is a large cavernous opening, the reservoir or milk cistern. This cistern is divided by constrictions into pockets of various sizes, into which the larger milk ducts empty. At the point of entrance of these ducts is a constriction due to a sphincter muscle. These sphincters can not close the entire opening, but it seems possible that they may partially do so, and this may thus account for the condition known to all dairymen as 'holding up the milk.'

"The large ducts ramify in an irregular manner to all parts of the gland. They subdivide into smaller ducts, and these in turn into smaller ones, until they terminate in a simple duct with its alveolus or pocket. The large ducts anastomose very freely, but do not in the smaller subdivisions. The canal in the teat, the reservoir, and ducts are lined with columnar epithelium, but just what part the epithelial cells lining these ducts have in the production of milk is not known.

"The alveolus is the sacculated distension on the end of the minute milk duct. It is the essential part of the gland. It is lined by a single layer of epithelial cells, which are especially concerned in milk secretion. The cavity of the alveolus in the cow is from $\frac{1}{250}$ to $\frac{1}{100}$ of an inch in length, and from 0.13 to 0.08 of an inch in diameter. The lining cells vary from almost a flattened form to a columnar form during the different stages of rest and activity.

"The mammary glands are abundantly supplied with blood. . . . The mammary artery has 4 principal branches, 2 going to the posterior gland, 1 branch between the glands, with nearly all its subdivisions entering the anterior gland. There is also a small branch for each rudimentary gland. The large branches subdivide within the gland tissue. . . . The larger volume of blood passes forward through the subcutaneous veins, thus bringing them into great prominence and giving rise to the popular name of milk veins. These abdominal veins enter the thoracic cavity just behind the sternum on each side of the cartilage, the point of entrance into the body being known as the 'milk well.' As the blood may pass to the heart through the posterior vessels as well as the anterior, it would seem that undue prominence is attached to these veins in judging the milking qualities of cows. If a large volume of blood should return by way of the posterior vessels, the abdominal veins will appear less prominent. One of the factors tending to increase the size of these veins is pressure upon the iliacs, as a gravid uterus. . . .

"The nerve center controlling secretion has not been located, but it is supposed to be in the spinal cord. It is possible that the will can exercise some influence, but the evidence is not sufficiently clear to warrant drawing a positive conclusion."

On the economy of heavy grain feeding of dairy cows, F. W. WOLL and W. L. CARLYLE (Wisconsin Sta. Rpt. 1899, pp. 52-67).—The proportion of grain feed to coarse fodder best adapted for the economical production of milk and butter was studied in an experiment with 2 lots of 4 cows each, lasting 3 months. A ration consisting of 8 lbs. of a mixture of ground oats, ground corn, wheat bran, and old-process linseed meal, 4 lbs. of mixed clover and timothy hay, and silage *ad libitum* was fed to lot A during the first and third periods, and to lot B during all 3 periods. During the second period lot A received the same ration except that the amount of grain was increased

to 12 lbs. In other respects the conditions of the experiment were uniform. The following table summarizes the principal data:

Results of feeding different amounts of grain to milch cows.

	Food consumed.			Total production.		Cost of food per 100 lbs. milk.	Cost of food per pound of fat.
	Silage.	Hay.	Grain.	Milk.	Fat.		
Lot A:	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Cents.</i>	<i>Cents.</i>
Period I (8 lbs. grain)	3,666	500	672	1,811.3	86.91	54.0	11.3
Period II (12 lbs. grain)	3,754	336	1,008	1,739.7	85.83	67.9	13.8
Period III (8 lbs. grain)	3,573	336	672	1,654.5	83.10	56.1	11.2
Average of periods I and III	3,620	418	672	1,732.9	85.01	55.1	11.3
Lot B:							
Period I (8 lbs. grain)	3,876	500	672	2,135.1	92.70	47.2	10.9
Period II (8 lbs. grain)	4,294	336	672	1,976.3	87.27	50.6	11.4
Period III (8 lbs. grain)	4,180	336	672	1,991.6	93.18	49.7	10.6
Average of periods I and III	4,028	418	672	2,063.4	92.94	48.5	10.8

The results are discussed at some length. The ration containing 12 lbs. of grain was considered as fed at a considerable loss as compared with the ration containing 8 lbs. of grain. No increase in the live weight of the animals nor favorable after effects on the production of milk and butter could be attributed to the additional amount of grain fed lot A during the second period. The work is considered as preliminary.

Protecting cows from flies, W. L. CARLYLE (*Wisconsin Sta. Rpt. 1899, pp. 92-96*).—A brief account is given of the appearance and life history of 2 species of flies troublesome to cattle, the common stable fly (*Stomoxys calcitrans*) and the horn fly (*Hæmatobia serrata*). Protection from the horn fly may be secured by spraying cows with various substances for this purpose, or by rubbing into their hair some greasy substance, such as fish oil with some oil of tar and sulphur added. Means of this kind and also blanketing were found useless against the more numerous stable flies.

An experiment was conducted to determine the relief from flies by stabling. Fourteen cows were divided into 2 lots as nearly equal in every respect as possible. During the daytime lot 1 was kept in a small paddock having an abundance of shade, and lot 2 in a comfortable stable provided with screen doors and windows. In other respects the 2 lots received the same treatment. The cows in lot 1 were constantly on the move fighting flies, while those in lot 2 were practically free from them. During the 4 weeks which the experiment lasted lot 2 (stabled) consumed 835 lbs. more of green sorghum and sweet corn than lot 1 and lost on an average 19 lbs. more in live weight per cow. Comparing the results of the first 2 weeks of the experiment with the results of the 2 weeks preceding, the yields of milk and butter fat of lot 1 decreased respectively 40.4 and 2.16 lbs., and of lot 2, 56.7 and 0.81 lbs. Similar results were obtained in comparing the first and fourth weeks of the experiment.

"This experiment can not be accepted as in any way conclusive, and yet it would seem to indicate that while the cows in the stable increased slightly more in the percentage of butter fat in their milk than did the lot in the paddock, yet they ate more of the feed and fell off more in the amount of milk given, though they decreased much less in total fat production. It is easily seen, however, that the increase in the total amount of butter fat given in the one lot over the other in this experiment was not sufficiently great to pay for the increased trouble and expense entailed in the stabling of the cows during the greater part of every day."

The effect on dairy cows of changing milkers, W. L. CARLYLE (*Wisconsin Sta. Rpt. 1899, pp. 89-91*).—The effect of the constant changing of milkers was studied with 8 cows in advanced stages of lactation. The experiment covered 5 periods of 4 days each. During the first, third, and fifth periods and for several days preceding each, the milking was done by the regular milkers. During the second and fourth periods each cow was milked by a different person at each successive milking. None of the milkers were strange to the cows. The data for the experiment are tabulated. With the regular milkers the average yield of all the cows for 4 days was 69.29 lbs. of milk, with an average fat content of 4.75 per cent. With changing milkers the yield of milk was 73.73 lbs. and the fat content 4.85 per cent.

"While the results would seem to show that there is a slightly increased production, on the average, from the constant changing of milkers, yet the increase is so slight that very little importance can be attached to it. The results of this experiment are important, however, in that they go to show that when all the cows in a herd are kindly treated by all the milkers, a changing of the milkers of the individual cows in the herd has no appreciable effect upon the milk and butter produced and it appears as if the cows appreciated a change."

Dairy herd record, W. L. CARLYLE (*Wisconsin Sta. Rpt. 1899, pp. 68-88, figs. 14*).—A dairy herd comprising 6 grade Jerseys, 6 grade Guernseys, and 6 grade Shorthorns was purchased to compare the cost of the milk and butter production of cows of the special-purpose dairy type, represented by the Jersey and Guernsey grades, and cows of the dual-purpose type, represented by the Shorthorn grades. The animals were of the highest dairy type of the breed and class to which they belonged. They were given the same care and treatment. Tables show the breed, age, and weight of cows; kind, amount, and cost of food eaten; number of days in milk; yields of milk and butter; and the value of products and total profit for each of 14 cows which were in the herd during the entire year. Of this number 3 were grade Jerseys, 5 grade Shorthorns, and 6 grade Guernseys. The average profit over cost of feed from each of these breeds was, respectively, \$59.05, \$50.71, and \$55.47 per cow. A grade Shorthorn gave the largest yield of milk and butter. The results of this preliminary work, while not considered conclusive, show a favorable comparison of the Shorthorn grades with the Jersey and Guernsey grades in the cheapness of butter production. An illustration is given of each of the 14 cows,

accompanied by descriptive and historical notes and a summary of her production and profit.

The composition of sow's milk, F. W. WOLL (*Wisconsin Sta. Rpt. 1899, pp. 267-270*).—One sample of milk from each of 2 pure-bred Poland China, 1 pure-bred Berkshire, and 2 grade Berkshire sows was secured in a manner similar to that described in an earlier report (E. S. R., 10, p. 782), and analyzed. The results of the 5 analyses, together with those of 7 analyses reported before, are summarized in the following table:

Composition of sow's milk.

	Lowest.	Highest.	Average.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Water.....	79.46	83.13	81.49
Fat.....	3.89	8.53	6.60
Casein and albumen.....	4.55	7.28	5.75
Milk sugar.....	3.07	6.20	5.19
Ash.....	.74	1.32	.97
Solids-not-fat.....	10.76	13.23	11.91

The results of 74 analyses made by the author and other investigators give 6.61 per cent as an average fat content of sow's milk. This is considered nearly 3 per cent higher than the average fat content of cow's milk produced in the United States. "Chemical analyses and microscopic examinations of the two kinds of milk show that sow's milk is more like the milk of strippers than that of cows in full flow of milk."

Pasteurization of milk and cream at 140° F., E. H. FARRINGTON and H. L. RUSSELL (*Wisconsin Sta. Rpt. 1899, pp. 129-139, figs. 3*).—The conditions of efficient pasteurization, thermal death point of the tubercle bacillus, and the cause of diminished consistency of pasteurized products are discussed, and studies on pasteurization at 140° F. are reported.

Samples of unpasteurized milk, and milk pasteurized at 140° F. for periods varying from 15 to 60 min., and at 155° for 15 min., were kept in cold running water, and the thickness of the cream layer formed in each case was determined at different intervals. The creaming property of the milk pasteurized at 140° was practically the same as that of the unpasteurized milk. As compared with normal milk the creaming of the milk pasteurized at 155° was retarded and lessened in quantity.

A number of tests were made to determine the keeping quality of milk pasteurized at 140° F. On the average unpasteurized milk remained sweet about 2 days. Milk pasteurized at 155° F. for 15 min. and at 140° for 15 and 30 min. remained sweet over 6 days with practically no difference in the 3 cases.

Determinations were made of the number of bacteria in samples of

milk heated for 20 min. at temperatures ranging from 45 to 70 °C. Over 99 per cent of the bacteria present in the unpasteurized milk was destroyed by pasteurization at 140° F.

Viscometer tests made according to the method previously described (E. S. R., 9, p. 181) showed practically no difference in the consistency of raw cream and cream pasteurized at 140° F. for 30 min.

The following summary is given:

“The temperature recommended for the pasteurization of milk and cream in the past has been 155° F. for a period of 15 to 20 minutes. This limit was chosen because it had been regarded as the point at which the tubercle bacillus is destroyed in a moist medium. When, however, cream or milk is heated to a temperature of 140° F. or above, the physical condition of the fat globules is changed so that cream appears much thinner and milk loses its property of rapid creaming. This objection can be overcome, as is shown by the preceding experiments, if milk or cream is not heated above this temperature.

“Not only is the creaming property of the milk, and the ‘body’ or consistency of cream unaffected, but the keeping quality is practically as good as it is where the product is heated to a temperature of 155° F. All that is necessary to secure good keeping quality is to destroy the vegetative bacteria, and as this is accomplished at the temperature of 140° F. if the exposure is made for a sufficient period of time, no advantage in this respect is to be gained by heating to a higher temperature. This being true, it only remains to determine with certainty how long an exposure must be made to destroy the tubercle bacillus. The temperature limit that has heretofore been considered necessary where the exposure was made at 140° F. was 1 hour, but recent extensive experiments by Theobald Smith, in which all conditions have been most carefully controlled, show that this time can be materially shortened where milk is agitated during pasteurizing. A thorough retest of this point is now being made under factory conditions and the exact time period will be determined on the basis of these trials.”

Pasteurization of skim milk, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1899, pp. 121-128, figs. 2*).—The methods and advantages of pasteurizing skim milk at creameries are discussed, and a device for heating skim milk by means of exhaust steam, constructed by J. C. Fortiner of the University creamery, is described.

This skim-milk heater consists of an ordinary tin pail which is suspended over the storage vat, and into which the pipe conveying the skim milk from the separator and the one conducting the exhaust steam from the creamery engine empty. The skim-milk pipe extends about 18 in. up into the steam pipe, which arrangement is thought to aid in utilizing all the heat of the exhaust steam and to prevent the skim milk from being blown from the pail by the steam. The skim milk is thus heated as it comes from the separator and flows over the top of the pail into the large vat from which the patrons of the creamery are supplied. In practice about 2,500 lbs. of skim milk per hour was heated to 160° F. and 4,000 lbs. to 140°. It was found that skim milk heated in this way remained sweet about 1 day longer than skim milk not heated. Only perfectly sweet milk can be used where this method of pasteurizing the skim milk is employed.

A valve for turning aside the exhaust steam when not needed for pasteurizing is illustrated. Brief mention is also made of an arrangement in practical use in a creamery by which the skim milk was heated in a similar manner at the separator.

Effect of salt on the water in butter, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1899, pp. 97-107, fig. 1*).—Reference is made to results of similar work reported previously (E. S. R., 11, p. 586).

In each of 18 experimental churnings the butter was divided into 2 lots, one of which was salted and the other not salted. In other respects the 2 lots in each case received as nearly identical treatment as possible. In a number of these trials both lots were worked once, and in the other trials the lots were worked twice, the 2 workings being separated by an interval of about 24 hours. Analyses of 36 samples of butter made in these trials are given in full and summarized in the following table:

Average of analyses of salted and unsalted butter.

	Number of churnings.	Salted butter.				Unsalted butter.			
		Butter fat.	Curd.	Ash (salt).	Water.	Butter fat.	Curd.	Ash (salt).	Water.
		<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Butter worked once	8	83.80	0.93	2.74	12.74	83.86	0.90	0.27	15.12
Butter worked twice	10	84.59	1.08	3.80	10.53	84.58	.96	.36	14.33

While the unsalted butter always had a dry appearance it was found in every comparison to contain more water than the salted butter.

“Taken as a whole, the analyses show that the higher the salt content, the less water the butter will contain. . . . The amount of water or brine that shows on the fresh-cut surface of butter is a better indication of its salt content than of the amount of water it holds. . . . The color of the salted butter was a darker shade of yellow than the unsalted. This was very noticeable.”

To observe the effect of the size of butter granules on the water content of butter, about 300 lbs. of ripened cream was divided into 2 lots, one of which was churned in a box churn until the butter granules were about the size of clover seed, while the other lot was churned in a combined churn and worker until the butter granules were about the size of corn grains. Both lots were salted and worked to the same extent except that one was worked on a table worker and the other in the combined churn and worker. Eleven trials of this kind were made. The average water content of the butter churned to large granules was 13.89 per cent, and of the butter churned to small granules 12.15 per cent.

In 10 comparative tests granular butter was divided into 2 portions, one of which was worked in a combined churn and worker and the other on a table worker. The average water content of the butter worked by the 2 methods was, respectively, 13.09 and 13.31 per cent.

"These results give practically the same average percentage of water in the butter worked by the 2 methods, showing in connection with the above experiment that the size of the granules of butter when churning stops has more influence on the amount of water left in the finished butter than does either of these 2 methods of working the butter."

White spots on butter, E. H. FARRINGTON (*Wisconsin Sta. Rpt. 1899, pp. 118-120, fig. 2*).—Tests were made to demonstrate the cause of white crystals entirely unlike mottles or white curd spots appearing on the surface of butter, especially on prints or bricks of butter in a refrigerator. Two 1-pound bricks from the same churning were kept at 50° F. in glass jars, one of which contained about 1 in. of water and the other the same quantity of sulphuric acid. The butter was raised above the liquid in each case. In the dry atmosphere of the jar containing the sulphuric acid crystals began to form on the surface of the butter within a few hours and nearly covered it in a few days. In the moist atmosphere of the jar containing the water no crystals formed on the surface of the butter, which, however, was covered with drops of brine. A second trial at 70° F. gave the same results. "Such spots are not an indication of defective salt, that the workmanship is poor, or the butter bad; they simply show that the butter has been kept in a cold place which at the same time was so dry that the water of the brine evaporated, leaving the salt on the surface."

The action of proteolytic ferments on milk with special reference to galactase, the cheese-ripening enzym, S. M. BABCOCK, H. L. RUSSELL, ET AL. (*Wisconsin Sta. Rpt. 1899, pp. 157-174, figs. 11*).—In the investigations here reported, the object of which was the differentiation of galactase from trypsin and other ferments, quantitative determinations were made of the different decomposition products formed by various ferments in sterilized milk. The ferments used were the enzymes galactase, trypsin, pancreatin, pepsin, and rennin, and the bacteria *Bacillus subtilis*, 2 species isolated from imperfectly sterilized milk and designated *B. 299* and *B. 83*, *B. acidilactici* and *B. coli communis*. Samples of fresh separator milk which had been sterilized were inoculated with these ferments and incubated at 37 to 38° C., for periods ranging from 1 to 16 weeks. Two per cent of chloroform was added to the samples inoculated with enzymes to prevent the growth of any bacteria present through possible contamination. The chemical analyses, which were performed in two independent series, involved determinations of the albumins and casein (precipitated by heat and acetic acid), albumoses (precipitated by zinc sulphate), peptones (precipitated by tannic and phosphotungstic acids), amids (not precipitated by reagents), and ammonia. The analytical methods employed are briefly described, a detailed account being given in a separate article (see p. 19). The results in detail are given in tables and are also shown graphically in a series of diagrams.

The progressive formation of soluble nitrogenous products by galactase, trypsin, and pancreatin differentiated these enzymes from pepsin and rennin, digestion with the latter enzymes and with commercial rennet extract taking place only in milk acidified with 0.2 per cent hydrochloric acid. The action of *Bacillus subtilis*, *B. 299*, and *B. 83* as regards the conversion of nitrogen into soluble form was similar to that of galactase. The amount of soluble nitrogen was not increased by *B. acidi lactici* or *B. coli communis*. Proteolytic changes in all cases were more rapid in the earlier than in the later stages of digestion, from 30 to 85 per cent of the total nitrogen being digested during the first 7 days. A differentiation of the proteolytic ferments was also shown by the character of the decomposition products. No ammonia was produced by trypsin, pancreatin, and pepsin. In samples of milk acted upon by galactase, *Bacillus subtilis*, *B. 299*, and *B. 83* for 112 days the nitrogen in the form of ammonia was respectively 0.04, 0.21, 0.11, and 0.15 per cent. In cheese 120 days old the ammonia was 0.17 per cent. Tryptic digestion was more rapid than that of galactase. The absence therefore of ammonia, together with the total disappearance of albumoses, and the presence of large quantities of amids and peptones in digestion with trypsin, and the presence of both ammonia and albumoses in digestion with galactase at the end of 112 days strengthened the conclusion that these two enzymes are not identical, although allied in some of their properties. The relative quantities of different end products of digestion, especially amids and ammonia, differentiated galactase from the bacterial enzymes.

The relation of galactase to other enzymes is considered in connection with the cause of the changes taking place in the ripening of cheese. "The similarity of products formed in the normal ripening of Cheddar cheese with those produced by galactase where all other factors are controlled, shows beyond all question that the main causal agent in the proteolytic changes that occur in these cheeses is due to this enzym."

Influence of galactase in the ripening of cottage cheese, S. M. BABCOCK, H. L. RUSSELL, and A. VIVIAN (*Wisconsin Sta. Rpt. 1899, pp. 175-178*).—Several experiments were made in a study of this question. In 2 experiments cottage cheese was made from normal milk, the acid being developed naturally by bacterial fermentation. In 1 of the experiments the curd was washed with warm water to remove as much acid as possible. In 2 other experiments cottage cheese was made from milk which had been heated to 192° F. for 20 minutes in order to destroy the inherent galactase. The acid was developed in one case by means of a buttermilk starter and in the other 0.5 per cent of commercial lactic acid was added. In each of the 4 experiments one portion of the curd was kept under chloroform. Determinations of the

total and soluble nitrogen at different periods during ripening are tabulated. The results are briefly discussed and the following conclusions are drawn:

"This series of experiments leads us to consider that the digestion of casein in cottage cheese is due, not so much to the action of vital ferments, in and on the curd masses as has hitherto been supposed, but to the effect of inherent milk enzymes, of which galactase is undoubtedly the most important. They also indicate that the lactic-acid group of bacteria have no appreciable effect on digestion.

"Furthermore, it is shown in these instances that the casein of milk, when precipitated by acid instead of rennet, undergoes a proteolytic or digestive change, in a manner comparable to that which occurs in normal milk."

Effect of digesting bacteria on cheese solids of milk, H. L. RUSSELL and V. H. BASSETT (*Wisconsin Sta. Rpt. 1899, pp. 187-193*).—Experiments were conducted to determine if losses occurring in the manufacture of cheese from tainted milks are due to the digestion of the casein of the milk by bacteria. Samples of raw and sterile milk inoculated with pure cultures of various species of digesting and gas-producing bacteria were incubated for 14 to 24 hours at temperatures ranging from 82 to 99° F. Determinations of the soluble nitrogen and the total solids of the milk and whey at the beginning and end of the experiments are tabulated. The results are considered as showing that the casein of the milk suffers no appreciable loss through the action of digesting bacteria during the first 24 hours after milking.

"It is therefore fair to assume that the losses sustained are attributable, in the main, if not wholly, to the manufacturing methods that are used in the handling of such tainted milks. This being the case, it is possible that improvements may be made in these methods whereby some, at least, of these losses may be prevented, a condition which would not in any way be possible if the insoluble casein was dissolved by these digesting organisms during the period before the milk is ordinarily made into cheese.

"It is more than likely that the digesting microbes attack the albumen in milk first, and so have in this already soluble material sufficient food to sustain them for a considerable period. Later, the insoluble casein molecule is rendered soluble through the continued activity of this type of ferment action."

Notes upon dairying in California and the export of California butter to the Orient, R. A. PEARSON (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 24, pp. 29, pls. 4, fig. 1*).—A brief account is given of the dairy exhibit at the California State fair, held at Sacramento September 4-16, 1899. Scores on the butter exhibited are tabulated. A résumé is given of the principal points brought out in a general discussion on the export of dairy products from the Pacific coast at a meeting of the California State Dairymen's Association, held at Sacramento during the fair. Among the phases of the subject discussed were causes affecting hardness of butter, making and packing butter for warm climates, and the use of preservatives. Some purposes of the experimental exports of butter to foreign markets by the Department are noted, and statistics are given of the exports of

butter and cheese from the United States to trans-Pacific countries from 1893 to 1899. The author discusses, with reference to conditions and practices observed in California, the use of sugar-beet pulp and sugar-beet tops for dairy cows, method of payment for milk at creameries, handling of milk from cows fed alfalfa hay, butter packages, cheese making, milk supply of cities, and dairy education in the State, offering suggestions for improvement along various lines.

The possibilities of dairying in Cuba, D. R. RANKIN (*Hoard's Dairyman*, 31 (1900), No. 17, pp. 336, 337).

Twelfth annual report of the dairy school at Rütli-Zollikofen, Bern, 1899 (*XII. Jahresbericht der Bernischen Molkereischule in Rütli-Zollikofen pro 1898-99*. Bern, 1899, pp. 44).

Summary of results of tests of new feeding stuffs at Poppelsdorf during the winter of 1898-99, E. RAMM (*Milch Ztg.*, 28 (1899), No. 52, pp. 817-819).—This is a summary account with tabulated data of a series of feeding experiments with milch cows, previously reported in detail (E. S. R., 11, pp. 81, 86, 885), comparing peanut cake with the following feeding stuffs: Tropon residue, brewery residue (Brauerschlempe), Illipe cake, palm-nut cake and Illipe cake, Tropon, English cake (consisting mainly of cotton-seed meal and molasses), malt-sprouts-molasses, gluten meal, and raw sugar.

Tests of dairy cows, 1898-99, J. W. DECKER (*Wisconsin Sta. Rpt.* 1899, pp. 140-152, fig. 1).—Official tests were made by representatives of the station during the year of 73 Holstein cows for the Holstein-Friesian Association, 7 Brown Swiss cows for the Brown Swiss Cattle Breeders' Association, and 2 Guernsey cows for the American Guernsey Cattle Club. The manner of conducting the tests is described and the results are tabulated and discussed. In tests of 5 Holstein cows a record was also kept of the amount and cost of food eaten during the 7 days.

Scale of points in use in the United States for judging the dairy breeds of cattle (*U. S. Dept. Agr., Bureau of Animal Industry Circ.* 27, pp. 16).—Reprinted from the Annual Report of the Bureau of Animal Industry for 1898 (E. S. R., 11, p. 983).

Eccentricities of the cow, C. D. SMITH (*Farm Students' Rev.*, 5 (1900), No. 6, p. 85).—Variations in the composition of milk during the same and succeeding periods of lactation are discussed.

Examination of milk for tubercle bacilli, V. H. BASSETT (*Wisconsin Sta. Rpt.* 1899, p. 205).—Thörner's method (E. S. R., 4, p. 214) was used in examining 4 samples of separator slime and 30 samples of milk coming from cows reacting to the tuberculin test.

"The result of these examinations showed that in no case were tubercle bacilli demonstrated in the milk from reacting cows that had no evident udder lesions of the disease. The accuracy of the method of examination is checked by the fact that in every instance where tuberculous sputum was added a positive microscopic result was noted."

Investigations on lactic acid fermentation and its practical use, S. EPSTEIN (*Arch. Hyg.*, 37 (1900), No. 4, pp. 329-359).

Testing cream (*Hoard's Dairyman*, 31 (1900), No. 18, p. 355).—The use of the Babcock test in determining the fat content of cream is briefly discussed.

On the composition of Norwegian creamery butter, F. H. WERENSKIOLD (*Norsk Landmandsblad*, 18 (1899), No. 50, pp. 607-611).—Gives the results of periodical examinations of the butter from nine creameries during 1899. Determinations of specific gravity (at 100° C.), refractive index, and Reichert number were made.—

F. W. WOLL.

Renovated butter and its identification, J. A. HUMMEL (*Farm Students' Rev.*, 5 (1900), No. 6, pp. 86, 87, figs. 3).

Annual report of the experiment station for cheese making at Lodi, 1898 (*Ann. R. Stat. Sper. Caseif. Lodi, 1899*, pp. 103).—The lines of investigation reported upon include the manufacture of several kinds of cheese, the influence of light on the souring of milk, the yield of cheese as affected by the use of soluble lime salts, a chemical study of the alluvial soils of Lodi, and the composition of various flours used in bread making.

Cheese factories of Roquefort, F. DONATI (*Ind. Lait.*, 25 (1900), No. 20, pp. 153, 154).—A descriptive account of the production of Roquefort cheese.

Coating cheese with paraffin to prevent mold, J. W. DECKER (*Wisconsin Sta. Rpt. 1899*, pp. 153, 154, fig. 1).—A number of trials of coating cheeses of different ages with paraffin were made by the author. When properly done the coating was a complete protection against the growth of mold. When the cheese was not carefully handled the paraffin would break away from the cheese and mold would grow beneath it. The coating of new cheese was thought to impair the flavor, while the coating of cheese 3 months old or older seemed to cause no injury in flavor. When cheese had been covered with a double bandage and paraffined, the outer bandage could be stripped off, leaving a fairly bright cheese. The cost of coating a 10-pound cheese was $\frac{7}{10}$ of a cent.

Examination of dairy salts, F. W. WOLL (*Wisconsin Sta. Rpt. 1899*, pp. 108-117).—A reprint of the main original data given in Bulletin 74 of the station (E. S. R., 11, p. 585).

Danish butter exports, 1898-99, B. BÖGGILD (*Tidsskr. Landökon.*, 1899, No. 12, pp. 540-548).—The exports of butter during the year October 1, 1898, to September 30, 1899, were as follows: To England, 140,894,253 lbs.; to Germany, 2,811,887 lbs.; to other countries, 662,794 lbs.; total, 144,368,934 lbs. Danish (1 lb. Danish=1.1 lbs. avoirdupois). The imports during the same period aggregated 34,289,831 lbs., making the net exports 110,079,103 lbs. 16,752,853 lbs. of butter was imported from Sweden, and 15,170,051 lbs. from Russia (Finland). About 3,500,000 lbs. of the butter exported was canned. The average price received for the export butter during the year was 25.8 cts. per pound Danish (23.5 cents per pound avoirdupois).—F. W. WOLL.

Denmark's production of milk and butter, 1897, B. BÖGGILD (*Ugeskr. Landm.*, 45 (1899), No. 47, pp. 585-587).—The author calculates on the basis of the latest official statistics that the total production of butter in Denmark in 1896 was about 129,030,000 lbs. Danish, and the total milk production, 4,502,780,000 lbs. The 1,145 cooperative and proprietary creameries in the country in 1897 made 116,126,000 lbs. butter and 19,048,000 lbs. (skim-milk) cheese, the average value received for the products at the factory being 23.9 cts. and 3.5 cts., respectively, per pound. The number of milch cows in the country, according to the census of 1898, was 1,067,138.—F. W. WOLL.

A new Belgian butyrometer, A. THEUNIS (*Ind. Lait.*, 25 (1900), Nos. 21, pp. 161, 162; 22, pp. 169-171, figs. 3; *Rev. Gén. Agron.*, 9 (1900), No. 2, pp. 50-60, figs. 3).—A new form of centrifugal fat tester devised by Mercier is figured and described. The test bottle is provided with a thistle tube through which the milk and the amyl alcohol and sulphuric acid used in the test are introduced. In comparison with the Gerber method the test gave closely corresponding results.

A composite milk-sampling pipette, J. W. DECKER (*Wisconsin Sta. Rpt. 1899*, pp. 155, 156, fig. 1).—A pipette designed by the author for taking composite milk samples is essentially a glass tube $\frac{1}{2}$ in. in diameter and about 12 in. long, graduated in $\frac{1}{4}$ in. spaces, the ends of the tube being somewhat constricted. In using the pipette a sample of milk is taken of as many spaces in the tube as there are pounds of milk to be sampled. The individual samples are then in proportion to the yields

of milk for the several milkings represented in the test. The average fat content of 10 composite samples, each representing 21 milkings during 7 days, taken in this way was 3.245 per cent, while the calculated average per cent was 3.27.

Officials, associations, and educational institutions connected with the dairy interests of the United States for the year 1900 (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 29, pp. 9*).—A list of each.

VETERINARY SCIENCE AND PRACTICE.

Report of the cattle quarantines in Canada from November 1, 1897, to October 31, 1898, D. McEACHRAN (*Ottawa: 1899, pp. 56*).—A report is given on the exportation and importation of animals and upon the diseases which were studied during the time covered by the report. These studies included work on tuberculosis, sporadic aphtha, a disease affecting the mouths and feet of cattle, resembling foot-and-mouth disease, Texas itch, hog cholera, swine plague, anthrax, glanders, actinomycosis, sheep scab, and enzootic ophthalmia in cattle and sheep.

The greater portion of the report is occupied with the report by J. G. Adams and C. F. Martin upon the cattle at the Experimental Farm at Outremont, Quebec, including studies upon the tuberculin test, the detection of tubercle bacilli in milk of suspected animals, the inoculation of guinea pigs and rabbits with milk from these animals, feeding calves with the milk of suspected animals, and a *post-mortem* examination of the cows. The results of these studies may be stated as follows: The 10 cows which reacted to the tuberculin test presented good evidences of tuberculosis upon *post-mortem* examination. The disease was not generalized in any of the cows, and there were only 4 cases of pulmonary lesions. Nine of the cows gave distinct evidence of the infection of the peri-tracheal lymph glands. In no case was there any infection of the mammary glands, although in one cow the supramammary lymph glands contained tubercles. It is possible that repeated large doses of tuberculin exercise a slight curative effect. Although the cows were free from tuberculosis of the udder the milk of several contained tubercle bacilli at times. Out of 44 guinea pigs and 42 rabbits inoculated with such milk only 2 guinea pigs and 1 rabbit died of generalized tuberculosis. Young calves fed entirely upon the milk of these infected cows for a period of several months remained wholly free from the disease, did not react to tuberculin, and showed no trace of tuberculosis upon *post-mortem*.

During the experimental period, the number of tubercle bacilli present in the milk increased greatly at times without any obvious cause. And it is therefore evident that the milk of such cows although usually not infectious may become so at any time.

Effect of different influences on normal temperatures of cattle and relation of same to tuberculin test, H. L. RUSSELL and V. H.

BASSETT (*Wisconsin Sta. Rpt. 1899, pp. 194-204*).—The authors conducted experiments for the purpose of determining the effect of ingestion of cold water upon the temperature of cattle. In a herd of 45 cows, 39 were allowed to remain out of doors for from 20 to 60 minutes where they had access to cold water. The other 6 cows of the herd were kept in the barn and were not watered. The cows were watered at 9 a. m. At 10 a. m. the average temperature of the cows which were watered was 100.19° F., and the average temperature of the cows which were not watered was 102.12° F. The average difference in temperature before and after watering was 2.17° , a fall of temperature being noticed in every case except two. The individual variation ranged from 0.9 to 5.1° . In order to determine the influence of the size of the animal upon the fall of temperature after drinking cold water, the herd was divided into 2 sections, the one composed of animals weighing 900 lbs. or more and the other of animals weighing less than 900 lbs. The average fall of temperature after watering in the first section was 2.02° and in the second section 2.3° .

An experiment was conducted with 15 cows for the purpose of determining whether the observed fall in temperature after watering could be attributed to exposure to the cold outside atmosphere. Eight of these 15 cows were watered in the barn and 7 were watered out of doors, the temperature of water in both cases being the same. The average fall of temperature in the cows which were watered in the barn was 1.66° and of those which were watered out of doors, 1.5° . It appears from this experiment that the fall in temperature is to be attributed solely to the ingestion of cold water.

In order to approach the problem from another side, an experiment was conducted in watering cows with water heated to a temperature of 101° F. The results showed that the variation in temperature after drinking this water was practically nothing. It is thus apparent that the ingestion of a large quantity of cold water during the reaction fever to the tuberculin test might lower the temperature of the animal to such an extent as to obscure the reaction and lead to a faulty diagnosis.

Experiments were conducted for the purpose of determining what influence, if any, thirst has upon the temperature of cattle. Observations on this point were made both in the winter and summer. The animals were allowed to thirst for 24 hours and their temperatures were then taken. The variation in temperature was so slight that it could be safely neglected in making tuberculin tests. Œstrum and parturition were observed to have only a very slight effect in elevating the temperature of cows. Dehorning caused a general rise in temperature in all the animals observed.

The general results of these experiments may be stated as follows: The ingestion of large quantities of cold water may produce a marked

fall in temperature. Where, however, the water is given frequently and in small quantities, the accuracy of the tuberculin test would probably not be affected. The observations which were made by the authors indicate that parturition, advanced gestation, and œstrum produce very slight fluctuations in temperature. The internal physiological conditions of the animals seem, therefore, to have less influence upon the temperature of the animal than external conditions.

The effects of eating moldy corn, A. W. BITTING (*Indiana Sta. Rpt.* 1899, pp. 44, 45).—A study of samples of moldy corn from different sources disclosed the presence of 3 organisms—1 bacterial organism and 2 molds.

Two horses were used for inoculation experiments, each receiving 5 cc. of an active growth of the bacteria hypodermically, and after 36 hours 10 cc. more. No pathological effects were produced. All 3 of the organisms were cultivated upon sterilized corn meal, which was then fed to the horses as a mash. The bacterial organism and one of the molds produced no effects. The other mold, a species of *Fusarium*, produced redness of the gums and some salivation. The animals had eaten about 5 lbs. per day for 5 days. On the fifth day one of the horses showed occasional pains and diarrhea. On the seventh day there were some muscular incoordination and stupor. The second horse exhibited some irritation of the mucus membranes of the mouth, but did not develop any nervous symptoms. The 2 horses together ate about 4 bu. of the moldy corn.

An experimental investigation of a dermatomycosis of fowls, L. MATRUCHOT and C. DASSONVILLE (*Rev. Gén. Bot.*, 11 (1899), No. 132, pp. 429-444, pls. 2).—The authors conclude from a study of this disease that the dermatomycosis, which heretofore has been called favus of fowls, and white comb, a comb disease, is quite distinct from favus and should be called by a special name. The organism which causes the disease is *Lophophyton gallinae*. The disease occurs spontaneously among gallinaceous birds, but not among mammals, and is quite different from the dermatomycosis of the hair of mammals. The organism of this disease produces only superficial lesions and in this respect is also different from favus. The organism in the lesions is characterized by a persistent mycelium of short joints of 3 to 4 cells.

In cultures no lateral chlamydospores appear. As regards the systematic position of *Lophophyton gallinae*, it seems to stand near the *Gynocia*.

The science of operations (Operationslehre), J. BAYER (*Vienna and Leipzig: W. Braumüller, 1899, pp. 522, figs. 451*).—This constitutes volume 1 of a handbook of veterinary surgery and obstetrics and presents a general discussion of surgical methods together with descriptions of the special technique of various operations.

The defense of the organism against the morbid properties of the glandular secretions, CHARRIN and LEVADITI (*Compt. Rend. Soc. Biol. Paris*, 52

(1900), No. 4, pp. 83-86).—The author's investigations indicate that the organism is protected against injurious properties of certain digestive secretions, especially the pancreatic juice, by substances which appear to be produced by the epithelial cells of the ileum.

Subcutaneous injections, F. ESCHBAUM (*Berlin. Tierärztl. Wehnschr.*, 1900, No. 4, pp. 39-41).—The author believes that the hypodermic injection syringe should be constructed with 2 or 3 rulings measured with special care, in order that the size of the dose may be accurately known. It is necessary to take into account the specific weight of the substances which are to be used in these syringes. The author recommends State inspection of hypodermic syringes.

Tuberculosis, MCFADYEAN (*Dairy*, 12 (1900), No. 134, p. 40).—Notes on the means of distribution of tuberculosis with special reference to tuberculosis of the udder.

On the frequency of tuberculosis, GUTBROD (*Wehnschr. Tierheilk. u. Viehzucht*, 44 (1900), No. 5, pp. 41-43).—Statistics of tuberculosis as found in slaughterhouses and an account of tuberculin tests in suspected cases.

Failures in the diagnosis by means of tuberculin, SWICKER (*Berlin Tierärztl. Wehnschr.*, 1900, No. 5, pp. 52-54).—The author believes that a considerable proportion of the causes of alleged failure of tuberculin is due to simple carelessness in labeling the animals during the tuberculin test. Where the test is applied simultaneously to a large number of cattle, the greatest care must be exercised to prevent mistakes in the identity of the records before and after injection.

Letters relating to the distribution of vaccine (*U. S. Dept. Agr., Bureau of Animal Industry Circ.* 28, pp. 9).—This circular contains a copy of a letter of the Secretary of Agriculture to Mr. H. R. Strong, a letter of Parke, Davis & Co. to the Hon. Jas. McMillan, a letter of the Secretary of Agriculture in reply to this last-named letter, and a letter from the H. K. Mulford Company to the Secretary of Agriculture, together with a reply to the same. These letters have to do with the question of the free distribution of vaccine by the Bureau of Animal Industry.

Pseudoscabies, A. W. BITTING (*Indiana Sta. Rpt.* 1899, pp. 43, 44).—Upon investigating an alleged outbreak of sheep scab, it was found that the trouble was due to the awns of *Stipa sparten*. These awns had evidently penetrated the skin of the sheep in the Southwestern States, from which they had been imported.

The so-called air-bladder mesentery of swine, SCHMUTZER (*Ztschr. Fleisch u. Milchhyg.*, 10 (1900), No. 5, pp. 89-95).—The author discusses the well-known appearance of small air bladders in the mesentery, especially of the small intestine in healthy pigs. From a careful study of a large number of cases, the author concludes that the gas contained in these bladders is not the product of micro-organisms and does not come from the intestine, but that it comes from the outside air.

Glanders and the sanitary law, O. LEBRUN (*Rec. Med. Vet. Paris*, 8. ser., 7 (1900), No. 1, pp. 32, 33).

The diagnostic value of mallein, E. ISEPPONI (*Schweiz. Arch. Thierh.*, 42 (1900), No. 1, pp. 1-20).—In a drove of 60 horses, 2 were suspected of having glanders, and mallein tests were given to these horses. The *post-mortem* examinations in these two cases furnished confirmation of the reaction which was obtained by the use of mallein. Mallein tests were made upon a number of other horses, and the details of the temperature conditions are given.

The author concludes that glanders often exists in a hidden form and that, therefore, mallein is a necessary agent in the eradication of the disease from a drove of horses. It is recommended that mallein tests be given at once to suspected horses, and that such as fail to react should be at once removed from quarantine.

The reliability of the Strauss method, C. TROESTER (*Ztschr. Veterinärk.*, 12 (1900), No. 2, pp. 69, 70).—As a result of considerable experience in diagnosing suspected cases of glanders, the author states that the Strauss method of inoculating male guinea pigs is perhaps the most reliable one for making correct diagnoses.

In order that this method may give the best results, however, it is necessary to make inoculations with material as fresh as possible. The glanders bacillus soon loses its vitality in material which is kept about the laboratory.

Statistical notes on periodical ophthalmia of horses, I. SHULZHENKO (*Arch. Vit. Nauk, St. Petersburg*, 29 (1899), No. 12, II, pp. 570-583).—Tabulated statements with a discussion on the frequency of this disease in different governments of Russia.

Composition of bones of sound horse and of bones of horse suffering with osteoporosis, H. H. HUSTON and A. H. BRYAN (*Indiana Sta. Rpt. 1899*, pp. 73, 74).—The humerus of each animal was taken for analysis. The bone of the normal horse was yellowish, while that of the diseased animal was gray and brittle. In the diseased horse a small gain of ossein was noticed. The most conspicuous changes in the bone of the horse suffering with osteoporosis were a reduction in the amounts of fat, phosphoric acid, lime, soda, and nitrogen-free organic matter.

Material for packing horses' hoofs, H. A. HUSTON and A. H. BRYAN (*Indiana Sta. Rpt. 1899*, p. 72).—A table is given showing the composition of substances to be used for this purpose.

On pseudotuberculosis, with special reference to pseudotuberculosis in birds, R. MUIR (*Jour. Path. and Bact.*, 5 (1898), No. 2, pp. 160-181, pls. 2).—The author conducted feeding experiments with guinea pigs. The article contains a discussion of the literature of the subject, with a bibliography.

AGRICULTURAL ENGINEERING.

Description of experiment station piggery, H. E. VAN NORMAN (*Indiana Sta. Rpt. 1899*, pp. 140-143, pl. 1, fig. 1).—The building is described and a general view and floor plan are given. The main part of the building is 22 by 46 ft. outside. On each side is a wing 12 by 14 ft. The front part only of the main building, 22 by 32 ft., is two stories high. The first floor contains 8 feeding pens, 4 of which communicate with sleeping pens in the wings of the building. The remainder of the floor space is occupied by a brood-sow pen, storage and attendant's room, scales, mixing vats, feed chutes, water hydrant, etc. The upper story of the building affords storage room for bedding, crates, and bin room for feed. "The building is so placed as to be centrally located among a series of feeding lots, all of which are connected to the building by lanes leading up to it. Each lot contains a small house for sleeping quarters."

Irrigation, L. JASTREMSKI (*Louisiana Planter*, 24 (1900), No. 25, pp. 394-397).—A paper read before the Central Louisiana Agricultural Society.

An electric-recording river gauge, W. M. FULTON (*Univ. Tennessee Record*, 1899, No. 11, pp. 232-243, fig. 7).—This is a description of a river gauge devised by A. Wade in the mechanical shops of the University of Tennessee.

Petroleum motors and their employment in agriculture, R. GAGEY (*Bul. Dir. Agr. et Com.*, 5 (1900), No. 15, pp. 63-81, fig. 3).

Tests of manure spreaders, BRUTSCHKE (*Mitt. Deut. Landw. Gesell.*, 15 (1900), No. 15, pp. 101, 102).

STATISTICS—MISCELLANEOUS.

Twelfth Annual Report of Alabama College Station, 1899 (*Alabama Sta. Rpt. 1899, pp. 32*).—This contains the organization list of the station; report of the treasurer for the fiscal year ended June 30, 1899; and reports of the director and botanist, chemist, associate chemist, veterinarian, agriculturist, and biologist and horticulturist, giving a general review of the station work during the year ended December 31, 1899. The report of the director contains in addition a summary of the contents of Bulletins 101–107 of the station, a list of bulletins now available for distribution, an exchange list of periodicals received at the station library, a list of seeds of trees furnished by this Department, and notes on the exhibit of cotton prepared by the station for the Paris Exposition.

Twelfth Annual Report of Georgia Station, 1899 (*Georgia Sta. Rpt. 1899, pp. 111–145*).—This embraces a brief account of the organization and work of the station during the year, a financial statement for the fiscal year ended June 30, 1899, and a report of the biologist and horticulturist containing an account of work with plums, grapes, and vegetables, and notes on plant diseases and insects.

Twelfth Annual Report of Illinois Station, 1899 (*Illinois Sta. Rpt. 1899, pp. 16*).—This includes a brief statement of the principal lines of station work, subject list of bulletins published since 1888, a detailed financial statement for the fiscal year ended June 30, 1899, and the organization list of the station.

Twelfth Annual Report of Indiana Station, 1899 (*Indiana Sta. Rpt. 1899, pp. 150*).—This includes the organization list of the station; a report by the director on the station work, staff, publications, and mailing list; miscellaneous articles noted elsewhere; acknowledgments; list of periodicals received at the station; and a financial statement for the fiscal year ended June 30, 1899.

Biennial Report of Iowa Station, 1898–99 (*Iowa Sta. Rpt. 1898–99, pp. 33–37, 77, 78*).—Notes on the work of the station, abstracts of Bulletins 37–43 of the station, and a financial statement for the fiscal year ended June 30, 1899, are included in these pages.

Seventeenth Annual Report of New York State Station, 1898 (*New York State Sta. Rpt. 1898, pp. 598*).—This contains the organization list of the station, the report of the treasurer for the year ended September 30, 1898, a meteorological record for the year, reprint of a station circular on the name of a new variety of cherry, and reprints of Bulletins 143–157 on the following subjects: Cottonwood-leaf beetle; green arsenite (E. S. R., 10, p. 467); a spraying mixture for cauliflower and cabbage worms (E. S. R., 10, p. 869); report of analyses of commercial fertilizers for the spring of 1898 (E. S. R., 10, p. 833); some experiments in forcing head lettuce (E. S. R., 10, p. 957); variety tests of strawberries, raspberries, and blackberries (E. S. R., 10, p. 961); report of analyses of commercial fertilizers for the fall of 1898 (E. S. R., 10, p. 1033); the economy of using animal food in poultry feeding (E. S. R., 11, p. 76); the raspberry sawfly, and preliminary notes on the grapevine flea-beetle (E. S. R., 11, p. 63); experiments in ringing grapevines (E. S. R., 11, p. 49); two destructive orchard insects (E. S. R., 11, p. 170); director's report for 1898 (E. S. R., 11, p. 295); commercial fertilizers for potatoes, II (E. S. R., 11, p. 235); sugar-beet investigations in 1898 (E. S. R., 11, p. 238); spraying cucumbers in the season of 1898 (E. S. R., 11, p. 257); and self-fertility of the grape (E. S. R., 11, p. 248).

Annual Report of South Carolina Station, 1899 (*South Carolina Sta. Rpt. 1899, pp. 37*).—This includes a general report on the work of the station by the vice-director and more detailed reports by the agriculturist, chemist, botanist, veterinarian, horticulturist, entomologist, and assistant agriculturist. The departmental reports give in some cases brief statements of the results obtained during the year. A financial statement for the fiscal year ended June 30, 1899, and a subject list of station publications are appended.

Sixteenth Annual Report of Wisconsin Station, 1899 (*Wisconsin Sta. Rpt. 1899, pp. 332, figs. 79*).—This includes the organization list of the station, a detailed account of the history and present status of the station, numerous articles noted elsewhere, lists of exchanges and acknowledgments, and a financial statement for the fiscal year ended June 30, 1899.

Distribution of the agricultural exports of the United States, 1894-1898, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 16, pp. 153*).—Statistical tables are given showing the quantities and values of all the various agricultural products exported from the United States to each country of destination during each of the 5 fiscal years 1894-1898. A summary is given showing the total values of agricultural exports by countries. The average annual value of the agricultural exports during the 5 years was \$663,536,201. The United Kingdom received 54.62, Germany 13.01, and France 6.63 per cent of the total exports. The United Kingdom also showed the greatest increase during the 5 years. A marked falling off in demands for American agricultural products was shown in case of Spain, Portugal, and European Russia. A summary of the distribution of agricultural exports by continents showed that Europe received 88.46 per cent.

Sources of the agricultural imports of the United States, 1894-1898, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 17, pp. 118*).—This is supplementary to Bulletin 16 of the Section (see above) and contains tables showing in detail the quantities and values of all the agricultural products imported into the United States from the several countries of supply during each of the 5 fiscal years 1894-1898. The average annual value of the agricultural imports during the 5 years was \$368,748,457. The articles most extensively imported were sugar and coffee. Of the total imports 16.17 per cent was supplied by Brazil, 10.14 by Cuba, and 8.97 by the United Kingdom. The imports from Japan, China, and the Hawaiian Islands showed the greatest increase and those from Cuba the most marked decrease during the 5 years. A classification of the agricultural imports by continents showed that about 30 per cent came from Europe, 23 per cent from South America, 23 per cent from North America, 16 per cent from Asia, 5.5 per cent from Oceania, and less than 2 per cent from Africa.

Our trade with Japan, China, and Hongkong, 1889-1899, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 18, pp. 168*).—Tables show the nature, quantity, and value of agricultural and nonagricultural products imported and exported by the United States in the trade with Japan, China, and Hongkong. The principal exports from the United States to these 3 destinations have been cotton, cotton manufactures, kerosene oil, wheat flour, and manufactures of iron and steel. These constituted nearly 80 per cent of the total exports in 1898. Silk and tea formed about 70 per cent of the total imports in 1898. The total value of exports have advanced from \$11,097,497 in 1889 to \$39,490,653 in 1899, and the total value of imports from \$35,196,670 in 1889 to \$47,815,035 in 1899.

Agriculture and animal husbandry in Denmark, Germany, and Great Britain, G. VON ZWEIFBERGK (*K. Landt. Akad. Handl., 38 (1899), No. 5-6, pp. 261-343*).—A report on the characteristic features of agriculture, with special reference to animal husbandry in the countries mentioned. The paper is accompanied by numerous half-tone reproductions of noted farm animals of different breeds.—F. W. WOLL.

NOTES.

COLORADO COLLEGE AND STATION.—J. D. Stannard, assistant in the department of civil engineering, has severed his connection with the institution to accept a position in the irrigation investigations conducted by this Office. J. A. Stump has been appointed his successor, and the duties assigned to him will be principally in connection with the college. B. C. Buffum, formerly professor of agriculture and horticulture at the Wyoming Experiment Station, has been elected professor of agriculture and agriculturist of the experiment station. He will begin his duties September 1. Miss Virginia Corbett, of the Montana Agricultural College, has been elected professor of English literature, to succeed Miss Jennie E. McLain. C. S. Crandall, who has been botanist and horticulturist of the station since 1890, resigned that position July 1 to enter the service of the Division of Forestry of the U. S. Department of Agriculture. Mr. J. H. Cowen, a graduate of the Colorado Agricultural College and for several years botanist and horticulturist, was appointed to succeed him. Mr. Cowen's sudden death at Ithaca, N. Y., is just announced. The station has begun the publication of press bulletins, which will be distributed to papers in the State and to a limited number of individuals. The mailing list of the station is being revised so as to give more attention to the needs of individuals and exchanges. Field work was carried on during the summer in irrigation and other related questions; also investigations on injurious insects and the adaptability of grains to high altitudes.

NEBRASKA STATION.—W. D. Hunter resigned his position as assistant entomologist July 1 to accept a similar position with the experiment station at Ames, Iowa.

NEW MEXICO COLLEGE AND STATION.—W. M. Reed has been appointed engineer of the station and professor of civil and irrigation engineering in the college. Fabian Garcia, formerly assistant in the department of agriculture and horticulture, has been made horticulturist of the station and assistant professor of horticulture in the college. R. F. Hare, first assistant chemist of the station and instructor in the college, has been promoted to the assistant professorship of chemistry in the college. J. J. Vernon has been recently appointed agriculturist. A small herd of well-selected cattle has been purchased, and in the future animal husbandry will be made an important part of the work of the college and station. T. D. A. Cockerell has resigned his professorship in the college to accept the chair of biology in the New Mexico Normal University at Las Vegas. His services are retained as consulting entomologist of the station. E. O. Wooten, botanist of the station, will henceforth have charge of all the biological work of the college. The agricultural course in the college has been greatly strengthened, and it is thought in the future will be one of the best proportioned and strongest courses offered in the agricultural colleges of the country. In addition to his duties as soil physicist and meteorologist, J. D. Tinsley will superintend the Roswell Substation, where drainage problems will have special importance.

TENNESSEE COLLEGE AND STATION.—The designs for the new dairy hall, mention of which was made in E. S. R. 11, p. 800, have been enlarged so that with its equipment it will cost something more than \$10,000. On the plats of the station favorable results have been secured with Canadian field peas and with rape. The experiments

with wheat, which have been conducted at the station, have proved very satisfactory, and the possibility of growing winter cereals seems well established.

TEXAS COLLEGE AND STATION.—At the annual meeting of the board of directors, July 6, P. S. Tilson, associate in chemistry, was relieved from duty in connection with the station, in order that he might devote his entire time to State fertilizer and college work. A station council has been provided for, to consist of the director, president, and chemist, with duties as yet undefined. The position of farm superintendent has been created in order that the care for the live-stock interests and field crops might be removed from the agriculturist and director. The determination of the exact duties of the position, together with a selection of a candidate, were assigned to a committee which has not yet made a report. This action has caused the name of H. C. Kyle to be dropped from the station rolls as foreman of the farm. The Texas Farmers' Congress held its third annual session at this place July 3-6, with 400 people in attendance. The proceedings will be published and distributed among the farmers, stockmen, and horticulturists of the State. The State Truck Growers' Association, State Floral Society, Central Texas Beekeepers' Association, and Texas Poultry and Pet Stock Association have become affiliated with the congress, and each is represented by a member on the general committee. The congress enthusiastically commends the work done on the several farms in connection with the station and college.

MISCELLANEOUS.—F. B. Smith, professor of agriculture in Wye College, England, is visiting this country for the purpose of making a study of the agricultural experiment station system and of seeing the various typical farm sections. He expects to visit a number of experiment stations before returning to England. A week was spent by him at the Department of Agriculture in familiarizing himself with the work of the different bureaus, divisions, and sections.

The Franklin Institute, of Philadelphia, has awarded the Elliott Cresson medal to Profs. W. O. Atwater and E. B. Rosa for their respiration calorimeter.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.¹
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH and V. A. CLARK.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. 2.

	Page.
Editorial note: International Congresses of Agricultural Experiment Stations and of Agricultural Education at Paris	101
New agricultural building at Kansas State Agricultural College	103
Recent work in agricultural science.....	106
Notes.....	200

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

New method for the gravimetric determination of reducing sugars based upon the use of the centrifuge, P. Chapelle.....	106
Simple and rapid method for the determination of the iodine number of fats, J. Bellier	106
The determination of glycogen, and relative quantities of glycogen in different parts of the flesh of a horse, J. K. Haywood.....	107

BOTANY.

On biastrepis in its relation to cultivation, H. de Vries.....	109
The influence of carbon dioxide on the form and structure of plants, E. C. Teodoresco	109
The influence of different kinds of light on the form and structure of plants, E. Teodoresco.....	110

¹ Absent on leave.

	Page.
The influence of changes of temperature on the respiration of plants, W. Pal- ladin	112
On the influence of anæsthetics on the respiration of plants, N. Morkowine...	112
Experiments on floral colors, P. Q. Keegan	113

FERMENTATION—BACTERIOLOGY.

Report of the bacteriologist, H. H. Lamson	117
Variability in the power of liquefying gelatin possessed by bacteria, H. W. Conn	114
Permanent forms of nitric and nitrous organisms, A. Beddies	114
On the nitrification of organic nitrogen, V. Omelianski	115
Denitrification and fermentation, K. Wolff	115
Recent investigations on the development of aromatic principles by alcoholic fermentation in the presence of certain leaves, G. Jacquemin	115
Investigations concerning bacteria in the fermentation of tobacco, J. H. Vern- hout	116
On the chemical nature of enzymes, O. Loew	117

METEOROLOGY.

Monthly Weather Review, Vol. XXVIII, Nos. 1-3	118
Maryland Weather Service, Vol. I	119
Meteorological observations at Michigan Agricultural Experiment Station for the year 1898, R. C. Kedzie	121
Meteorology, C. H. Pettee	120
Meteorological summary for Ohio, 1898, C. A. Patton	120
Meteorological observations, W. B. Alwood	121
Relations between the annual variations of temperature and the successive phases of vegetation, A. Desmoulins	120

WATER—SOILS.

The fruit soils of Virginia, W. B. Alwood	122
Analyses of soils, C. F. Juritz	122
The behavior of water-soluble phosphoric acid in the soil, M. Ullmann	123
Cultivation and weeding, P. P. Dehérain	123
A new method for the mechanical analysis of soils, G. Scarlata	123

FERTILIZERS.

Denitrification and the decomposition of animal excrement in the soil, C. Rogoycki	124
Ground bone compared with superphosphate and Thomas phosphate as sources of phosphoric acid, U. J. Mansholt	125
Introduction to field experiments with fertilizers, A. L. Knisely	125
Field tests with fertilizers on heavy clay lands, H. A. Huston	126
The maintenance of fertility, C. E. Thorne	127
Commercial fertilizers, S. W. Johnson, E. H. Jenkins, et al.	128
Commercial fertilizers, M. A. Scovell, A. M. Peter, and H. E. Curtis	130
Analyses of commercial fertilizers, W. C. Stubbs	130
The production of the Stassfurt deposits in 1899, Maizières	130

EXPERIMENT STATION RECORD.

VOL. XII.

NO. 2.

The International Congress of Experiment Stations, held in Paris in connection with the exposition, was the third of its kind, although less of international interest has attached to the two previous ones. All three of these international congresses have been held at or near Paris. The first convened at Versailles, in June, 1881, following the marked activity in the organization of experiment stations which occurred throughout Europe a few years previous to that time. The second congress was held at Paris in connection with the Universal Exposition of 1889. The third, which in point of attendance at least was to a greater extent international than the two preceding, met June 18 to 22, 1900. Seventeen countries in which experiment stations are maintained were represented by delegates, although in some cases the representation was smaller than would have been expected. No delegates were present from Russia, Norway, Sweden, Spain, or Canada. The enrolled membership was nearly two hundred, of whom sixty were directors of stations. Only accredited delegates were admitted to the congress, and cards of admission were issued upon registration.

The congress was presided over by Casimir-Perier, president of the *Société nationale d'encouragement à l'agriculture*, whose linguistic attainments specially fitted him for the position. The secretary of the congress was Louis Grandeau, director of the *Station agronomique de l'Est*. After an opening address by the president, M. Grandeau addressed the congress upon the history and development of the experiment station idea throughout the world. He gave particular attention to the stations of the United States, and highly commended their scope, facilities, and the character of their work. The provisional programme which had been sent out early in the year was then presented. The first day's sessions were taken up with the reading and discussion of papers relating to soils, fertilizers, and field tests. The sessions of the second day were occupied with papers on feeding animals, analyses of wine, cider, dairy products, seeds, etc. The closing session was devoted principally to questions of station organization and methods of investigation. The desirability of uniformity in methods of analysis, and where practicable in agricultural investigation, formed a quite prominent feature of the discussion, and upon the recommendation of the directory a resolution was introduced, which was

unanimously adopted, looking to the establishment of an international commission to secure uniformity of methods of investigation in all the experiment stations of the world. The plan of organization of this commission will be announced later.

The desirability of international methods is thoroughly appreciated in this country, where for a number of years past the Association of Official Agricultural Chemists has used its efforts to that end. Some success has followed the attempts to secure international cooperation in testing the methods adopted by the Association and those in use in foreign countries, but it has been impossible to get the work upon a satisfactory basis or make it official in an international sense. The establishment of a commission for this purpose will accordingly meet with approval in this country, and if it fulfills its mission this will be an important outcome of the congress.

The experiment station congress was preceded by the International Congress of Agricultural Instruction under the same presidency, with M. Lagorsse as secretary. In many instances the same delegates represented their countries at both conferences. The topic given principal consideration at the Congress of Agricultural Instruction was the teaching of agriculture in France, and the congress adopted resolutions looking to the better organization and coordination of agricultural education in the various sections of the country.

The two congresses were terminated by a banquet at Hotel Continental on the evening of June 21, at which about 150 persons were present. Several excursions were arranged for the benefit and pleasure of those in attendance at the congresses, and visits were paid to the laboratory of the *Compagnie générale des voitures*, where extensive experiments have for years been conducted upon the feeding of horses, to the experimental fields of the *Station agronomique de l'Est* at *Parc des princes*, and to the *Institut national agronomique*, where the various laboratories were inspected.

NEW AGRICULTURAL BUILDING AT KANSAS STATE AGRICULTURAL COLLEGE.

Agricultural Hall, the new agricultural building recently completed at the Kansas State Agricultural College, is a handsome structure of white Manhattan limestone, 90 by 95 feet. (Fig. 1.) It contains two stories and a basement, and cost, with equipment, \$81,000. It stands

FIG. 1.—Agricultural Hall, Kansas State Agricultural College.

upon the former site of the president's residence, which was destroyed in 1895.

The first floor contains two good-sized offices, an agricultural library, cheese room, milk room, butter room, testing room, and cold-storage rooms. (Fig. 2.) The sides and ceilings of all the working rooms on this floor are covered with white opalite tiling, and the floors are laid with monolith tiling. The opalite tiling is made of tempered glass.

and is much cheaper than the ordinary porcelain tiling. If it proves satisfactory in the dairy rooms of this building, it is cheap enough for general use in creameries.

The second story contains three large lecture rooms for agricultural classes, two offices for instructors, and a cloak room. (Fig. 3.) The largest of the lecture rooms has a seating capacity of about 200, and may be used for institutes or other agricultural meetings.

FIG. 2.—Plan of first floor, Agricultural Hall.

The basement contains a boiler room, engine and refrigerating room, lavatories and bathrooms, three insulated cheese cellars, and a large storage room. The refrigerating apparatus is planned to be available in all workrooms, in the cold-storage rooms, and in the cheese cellars, the arrangement in the cheese cellars being designed to maintain any degree of temperature at will.

All the workrooms are furnished with hot and cold water and steam, and the entire building is lighted by electricity. Power is supplied both by electric motor and steam. The refrigerating plant has not yet

FIG. 3.—Plan of second floor, Agricultural Hall.

been installed, on account of lack of funds. With this exception the building is equipped with all the modern apparatus for factory and farm butter making, cheese making, testing and handling milk.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

New method for the gravimetric determination of reducing sugars, based upon the use of the centrifuge, P. CHAPELLE (*Rev. Chim. Analyt. et Appl.*, 5 (1900), No. 2, pp. 41-44).—It is stated that the quantity of oxid of copper precipitated by Fehling's solution is not exactly proportional to the sugar used, but is a function of the dilution of the solution and excess of copper. When working with constant dilution, the only cause of trouble is the excess of copper, and it is easy to determine the value of that. A measured quantity of sugar solution insufficient to obtain complete reduction and 25 cc. of Fehling's solution are used. The total volume is then made up to 37½ cc.

The tubes containing the mixed solution are heated for 3 or 4 minutes in a calcium chlorid bath at 108 to 110°. They are then whirled in a centrifuge, and the copper adheres to the sides. The liquid is decanted and the copper precipitate washed with water, dried and weighed. It is stated that when 250 mg. of copper precipitate are obtained duplicates agree within ½ mg. A table is given, showing the amounts of glucose, lactose, sucrose, etc., corresponding to different weights of cuprous oxid.

In the succeeding number of the journal (No. 3) the application of this method to the determination of the sugars in milk, blood, wine, urine, etc., is considered.—H. SNYDER.

Simple and rapid method for the determination of the iodine number of fats, J. BELLIER (*Rev. Chim. Analyt. et Appl.*, 5 (1900), No. 4, pp. 128-134).—Hübl's method is considered as requiring too much time. The attempts to simplify the method by Wys and others are noted. The author uses a solution containing both iodine and bromine dissolved in acetic acid; 50 gm. of iodine and 32 gm. of bromine are dissolved in 950 cc. of acetic acid. The solvent for the fatty body is composed of chloroform, mercuric chlorid, acetic acid, and potassium iodid. One gram of material is dissolved and the bromine-iodine solution added until a permanent coloration for 5 minutes is secured, and the number of cc. of solution used gives directly the iodine number. It is claimed that the results obtained are practically the same as those by the Hübl method. The iodine number of a few oils as obtained by this method is given.—H. SNYDER.

The determination of glycogen, and relative quantities of glycogen in different parts of the flesh of a horse, J. K. HAYWOOD (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 2, pp. 85-93).—After testing a number of different methods for glycogen the author worked out the following, which is a modification of the Brücke method: From 50 to 60 gm. of ground meat is treated with 300 cc. of 1 per cent potassium hydroxid and heated on a steam bath for about 6 hours, water being added from time to time. The solution is evaporated to about 150 cc., made slightly acid with hydrochloric acid, and hydrochloric acid and double iodid of potassium and mercury added alternately until all proteid matter is precipitated. The solution is made to a volume of 500 cc. and an aliquot filtered and exactly neutralized with concentrated potassium hydroxid. Three or four drops of concentrated hydrochloric acid is added and twice the volume of 93 to 95 per cent alcohol, the precipitated glycogen filtered off after standing 2 or 3 hours, washed with alcohol and ether, dried at 80 to 100° C., then at 115° C., and weighed. After weighing, the filter is thoroughly extracted with boiling water, dried at 115° C., and again weighed, the difference in weight representing glycogen.

The author believes the method to be an improvement over the original Brücke method and sufficiently accurate for distinguishing horse meat from other meats.

Analyses are given of the chuck, rib, and flank of 3 different horses, and of the different cuts of meat from another horse.

The oxid of iron and alumina in mineral phosphates and superphosphates, MORIMONT (*Bul. Assoc. Belge Chim.*, 14 (1900), No. 1, pp. 16-18).—Known amounts of iron and alumina oxids, when present in superphosphates, were determined by the method based upon Kroker's reaction (insolubility of iron and aluminium phosphates in acetic acid). The amount found exceeded the calculated and known amounts. It was the opinion of the author that the difference was caused by the presence of large amounts of lime.—H. SNYDER.

Résumé of the most important investigations in sugar chemistry during the last half of the year 1899 (*Deut. Zuckerind.*, 25 (1900), No. 5, pp. 177-181).

Studies on the progressive development of the essence of bergamot, E. CHARABOT (*Compt. Rend. Acad. Sci. Paris*, 129 (1899), No. 19, pp. 728-731).

On the determination of pentosans, W. L. A. WARNIER (*Bul. Soc. Chim. Paris*, 3. ser., 21 (1899), No. 10, p. 527).

Automatic apparatus for the estimation of pentosans, V. STANĚCK (*Böhm. Ztschr. Zuckerind.*, 24 (1899), pp. 227-230; abs. in *Jour. Chem. Soc. [London]*, 78 (1900), No. 451, II, p. 373).

An apparatus for washing and absorbing gas, A. GAUTIER (*Bul. Soc. Chim. Paris*, 3. ser., 23 (1900), No. 5, pp. 141-144, fig. 1).

A simple gas generator, C. E. WAIT (*Univ. Tennessee Record*, 1899, No. 11, pp. 259, 260, fig. 1).—A simple, cheap, and effective apparatus is briefly described and illustrated.

A rubber mortar-cap for pulverizing with exclusion of air, R. SCHOLL (*Chem. Ztg.*, 24 (1900), No. 3, p. 15, fig. 1).—A flexible rubber sheet which fits securely over the top of the mortar, with a hole in the center for the pestle.—J. T. ANDERSON.

A universal pipe-stem triangle, L. MARTIUS (*Chem. Ztg.*, 24 (1900), No. 3, p. 15, fig. 1).—Two of the sides of the triangle are fixed in the usual way, while the third arm is hinged at one point with the other end free, thus allowing the size of the triangle to be shifted at pleasure. A notched wire, running parallel to one of the sides of the triangle, holds the free end of the movable side securely in any desired position.—J. T. ANDERSON.

New triangles for crucibles and dishes, A. HEBEBRAND (*Chem. Ztg.*, 24 (1900), No. 5, p. 37, figs. 2).—The crucible or dish is supported on three platinum pegs screwed into the side of an iron triangle vertically to these sides, and at angles of 45° to their plane.—J. T. ANDERSON.

BOTANY.

On biastrepis in its relation to cultivation, H. DE VRIES (*Ann. Bot.*, 13 (1899), No. 51, pp. 395-420).—The author designates under the term biastrepis the twisting of the stem which sometimes occurs in plants, the normal shoots of which have opposite or whorled leaves. By this twisting the phyllotaxis becomes spiral instead of verticillate, and the successive leaves of the spiral are connected by their bases.

A large number of experiments with *Dipsacus sylvestris torsus* are reported, from which it is concluded that under proper cultivation the seeds of this plant will yield about one-third twisted stems. This proportion was first attained in the fourth generation, and since then the proportion has increased.

The phenomena of biastrepis depend not only upon the hereditary properties of the seed, but also upon the external conditions under which the individual develops. The more favorable the conditions of life the richer is the progeny obtained from any given seed in individuals with twisted stems, and the more marked is the twisting in individuals. The importance of plenty of space, time of sowing, and character of soil are pointed out.

From these experiments the general statement is made that with a given hereditary tendency, any monstrosity becomes more marked the more favorable the conditions of life, and, therefore, the more vigorous the growth. This is true not only of *Dipsacus sylvestris*, but is established for most various plants and different monstrosities by observations made by the author during the past 10 years.

The influence of carbon dioxide on the form and structure of plants, E. C. TEODORESCO (*Rev. Gén. Bot.*, 11 (1899), No. 132, pp. 445-470, pl. 1, figs. 18).—A report is given of a series of experiments in which a number of plants were grown with and without carbon

dioxid. An apparatus was devised by which air free from carbon dioxid could be supplied to one bell jar, and to another an atmosphere containing approximately 2 per cent of carbon dioxid. By means of an aspirator the atmosphere was constantly changed. The plants used were *Marchantia polymorpha*, *Lunularia vulgaris*, *Lupinus albus*, *Phaseolus multiflorus*, *Faba vulgaris*, *Pisum sativum*, *Asparagus officinalis*, *Cucurbita pepo*, *Borrago officinalis*, and *Datura stramonium*.

The morphology of thallus, stem, and leaves is fully described. In the case of the hepatics, the thallus was less developed, less branched, and no asexual reproductive organs were produced when grown in an atmosphere free from carbon dioxid. The assimilative tissues, usually present in the large air cavities, were wholly absent in the case of *Marchantia* and greatly reduced in *Lunularia*. The air spaces were likewise either wholly or nearly obliterated.

Where plants were cultivated from seed, the stems for a time grew best in an atmosphere which did not contain carbon dioxid, the presence of that gas retarding the consumption of the reserve material. However, after the plant had used up its reserves and chlorophyll assimilation begun, the best growth was obtained in an atmosphere containing carbon dioxid. Those plants which were not cultivated from seed, but were already in an advanced stage of growth, did not show the preliminary phase just described, but continued their growth best in the atmosphere charged with carbon dioxid. The leaves of the plants were smaller when grown without carbon dioxid. In the case of the *Datura* leaves, those already formed, when placed in an atmosphere lacking in carbon dioxid, became yellow and fell off. In nearly every case the leaves were thicker and the palisade parenchyma longer and larger, the air spaces more developed, with all plants which grew in the atmosphere charged with carbon dioxid. The internodes in general section were larger, the number of fibro-vascular bundles greater, and the individual bundles developed to a greater extent.

The influence of different kinds of light on the form and structure of plants, E. TEODORESCO (*Ann. Sci. Nat. Bot.*, 8. ser., 10 (1899), Nos. 3-4, pp. 141-256; 5-6, pp. 257-264, pls. 4, figs. 20).—In order to study the effect of rays of different refrangibility on the form and structure of plants, the author made use of the spectrum and colored screens, the colors used being red, blue, and green, and comparisons were made with plants grown in light and darkness. The effect of these different lights, as shown by the morphology and anatomy of leaf, stem, and root, were studied, the experiments being described in detail. The following plants were used: Horse beans, white lupines, buckwheat, castor beans, peony, evening primrose, *Rubus fruticosus*, live-forever, peanut, vetch, white beans, pepper grass, chick-pea, gourd, sunflower, hemp, horse-chestnut, potato, ash tree, maple, oak, and syringa.

The principal results are summarized as follows:

The greatest expanse of leaf blade was in those plants under blue light, the least under the green light, with the red intermediate. Those under the blue light approached most nearly to the total illumination and the green to darkness. The effect on the petioles varied but in two ways. In one series the green rays produced the longest petioles, with the shortest under the blue, and intermediate under red illumination. In the other the order was reversed. With those plants having a rosette of root leaves the longest leaves grew under the green screen and the shortest under the blue, with red intermediate. At the same time the longest leaves were not always the largest. All the different colored lights were less favorable to the development of the tissues of the leaves than the white light.

The amount and development of the palisade tissue, parenchyma, and air spaces were least under green light, greater under red, and most highly developed under blue light. The chloroleucites, so far as number, size, and disposition were concerned, were similar in development to the assimilative tissues. Under the green light they were small, fewer, of indefinite shape, and distributed without any order in the cell and did not contain as much chlorophyll as either under the red or blue. The number of stomata per unit of leaf surface was greatest under the green light, less under the red, and least under the blue. The development of wood, liber, and cambium of the veins, as well as the lignification of the cell walls of the leaves, was the same as in the stems and roots.

The studies of roots showed that for plants whose roots are retarded by white light, blue light retarded them still more, while under green light they attained greater length, although the maximum development was in darkness. When roots developed better in light than in darkness they showed increased growth under blue screens and made little increase under green. When growing equally as well in light and darkness the different colored lights made no appreciable difference. The maximum diameter of the central cylinder and thickness of cortex of roots was shown in the plants grown under red and blue light, with green as the minimum. Under the green light the primary wood presented few vessels and the differentiation of secondary tissues was less advanced. The same was true for the lignification of cell walls and supporting tissues. Under the green light the structure of roots approached those grown in darkness, while those under blue light were more nearly like those grown under white light.

The investigations showed that the green light gave the greatest growth of stem, followed by red and blue when the experiment was not continued beyond the consumption of the reserve materials of the plant. When conducted longer the plants under green light perished.

The development of the primary and secondary conductive tissue and lignification of cell walls was the same as for the roots. The central cylinder of the stem increased most rapidly under blue light and least under green, with red as intermediate. The periderm of the stem was least developed under green light, most under blue, and red intermediate.

The influence of changes of temperature on the respiration of plants, W. PALLADIN (*Rev. Gén. Bot.*, 11 (1899), No. 127, pp. 241-257).—The extremities of etiolated seedlings of *Vicia faba* with a few leaves were cut off and placed in vessels containing a 10 per cent solution of saccharose. One lot was kept in the laboratory at an average temperature ranging from 17 to 20° C. A second lot was placed in a vestibule where a lower temperature, 7 to 12° C., was experienced, and the third lot was placed in a thermostat in which a temperature of from 36 to 37.5° C. was maintained. After from 3 to 7 days in these temperatures equal lots were brought together and kept at a medium temperature of from 18 to 22°, and the amount of carbon dioxid liberated per gram of plants was ascertained.

It was found that the plants which had been kept in the medium temperature gave off 55.8 mg. per gram; those removed from the low temperature to the medium gave off 78.1 mg.; and those from the highest to the medium temperature, 85.4 mg. per gram of plant weight. The change from a lower to a higher or a higher to a lower temperature resulted in an increased respiration. The cause for this phenomenon was not ascertained.

On the influence of anæsthetics on the respiration of plants, N. MORKOWINE (*Rev. Gén. Bot.*, 11 (1899), Nos. 128, pp. 289-303; 129, pp. 341-352).—The author experimented with the etiolated leaves and leaf buds of *Vicia faba* and *Lupinus luteus* and the green leaves of *Ficus elastica* and *Phylodendron* sp.; also upon the embryos of sprouted wheat. As anæsthetics, alcohol, ether, hydrochlorate of morphine, and hydrochlorate of solanin were used. The plants were placed in a Pettenkofer apparatus and the respiration determined. The experiments are described in detail.

Contrary to the conclusions of Bonnier and Mangin,¹ the author found that if the exposure to anæsthetics be prolonged for quite a number of hours, or even for several days, the intensity of respiration was considerably increased. Under the influence of alcohol, the intensity of the respiration of etiolated plants was increased 1½ times. With ether, the respiration of etiolated leaves of *Vicia faba* was more than doubled. It was found that the hydrochlorate of morphine, 1:2,000, did not in any way affect the respiration of plants. When, however, the quantity of morphine was 1:500, the respiration of the plants was increased 1½ times.

¹ Ann. Sci. Nat. Bot., 7. ser., 1886, p. 5.

In general, the author states, his experiments show that anæsthetics increase the respiration not only in etiolated but in green plants. Incidentally, the effect of anæsthetics on chlorophyll was investigated, and it was found that a 5 per cent solution of alcohol checked the chlorophyll production and growth of the wheat germ. The diminution in the respiration in the case of the plantlets was in proportion to their growth.

Experiments on floral colors, P. Q. KEEGAN (*Nature*, 61 (1899), No. 1570, pp. 105, 106).—The author conducted a series of experiments to determine the true color of anthocyan—that is, the blue and red pigment of flowers. The opinions of Berzelius and Wiesner are stated, in which diametrically opposite conclusions are given.

The author observed the effect produced by immersion of fresh petals of a number of flowers into ether saturated with ammonia. The petals of the peony, pink, campion, deep-red rose, sweet pea, vetch, mallow, balsam, geranium, fuchsia, scarlet rhododendron, crimson flax, and blue centaurea became blue; of the red daisy, periwinkle, and lady's smock, bluish green; while the petals of anemone, larkspur, violet, willow herb, scarlet Tropæolum, red rhododendron, flowering currant, scabious, wild thyme, potato, and forget-me-not became green.

Later the coloring matter was withdrawn from the petals by macerating them for 2 days in methyl alcohol, after which the solution was drawn off, evaporated to dryness, the residue dissolved in warm water, and after filtering was tested with hydrochloric acid, ammonia, lead acetate, and magnesium acetate, the color reaction in each case being given.

The author's conclusion is that there are different stages in the development of floral pigments. In the lower stages the natural color is red, whatever the chromogen may be. In the higher stages the natural color of the anthocyan is blue, or is capable of forming blue compounds with alkalis and certain metallic salts.

On the presence of vanadium, molybdenum, and chromium in plants, E. DEMARCAZ (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 2, pp. 91, 92; *abs. in Rev. Sci. [Paris]*, 4. ser., 13 (1900), No. 3, p. 88).

On the composition of the leaves of the plane tree from the standpoint of nutritive material and on the migration of this material during growth and after the death of the leaves, G. M. TUCKER and B. TOLLENS (*Ber. Deut. Chem. Gesell.*, 32 (1899), pp. 25-75; *abs. in Bul. Soc. Chim. Paris*, 3. ser., 24 (1900), No. 10, p. 480).

On the modifications which oil of lavender undergoes during the growth of the plant, E. CHARABOT (*Bul. Soc. Chim. Paris*, 3. ser., 23 (1900), No. 5, pp. 183-189).

Behavior of leguminous tubercles in water culture, F. NOBBE and L. HILTNER (*Landw. Vers. Stat.*, 52 (1899), Nos. 5-6, pp. 455-465).—In experiments with seedlings of *Robinia pseudacacia* grown in water cultures, the root tubercles functioned

normally in air, but under water almost none at all. The authors believe that the results obtained in these experiments demonstrate that nitrogen assimilation takes place within the root tubercles and not in the leaves.

Further observations on Nitragin and on the nature and functions of the nodules of leguminous plants, M. DAWSON (*Proc. Roy. Soc. [London]*, 66 (1900), No. 425, pp. 63-65).

A new departure in cytology (*Nature*, 61 (1900), No. 1582, pp. 385-387).—A review of a recent work by A. Fischer, of Leipsic.

FERMENTATION—BACTERIOLOGY.

Variability in the power of liquefying gelatin possessed by bacteria, H. W. COXN (*Centbl. Bakt. u. Par., 2. Abt.*, 5 (1899), No. 20, pp. 665-669).—On examining specimens of milk from a neighboring dairy, the author discovered 2 rather constant organisms in his cultures. The first was a *Micrococcus* and seemed to be almost universally found in all the specimens of milk. Its morphology is described at some length. With it, and almost equally abundant, was found a bacterium which differed from the first in having no power of liquefying gelatin. As experiments with the organisms were continued, it was found that intermediate grades existed between the two, and after continuing the experiments for several months, the author arrived at the conclusion that he had one organism which showed a wide variability. Subsequent study of the culture proved that with the exception of the power of liquefying gelatin the organisms were absolutely identical.

Permanent forms of nitric and nitrous organisms, A. BEDDIES (*Chem. Ztg.*, 23 (1899), No. 63, pp. 645-647; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 446, II, p. 34).—From manure, sewage, etc., the author prepared nutritive solutions containing about 2 gm. each of organic and inorganic matter per liter. These were mixed with 1 to 2 per cent of meat juice and the nitrogen content was raised to about 3 per cent by the addition of ammonium sulphate. The alkalinity was raised or lowered as desired by the addition of sodium carbonate or phosphoric acid, and, after sterilizing, the solutions were inoculated with 0.1 to 0.2 gm. of soil containing the nitrifying organisms. The cultures were kept in diffused light at 20 to 25° until nitrification was complete (2 to 3 months). Material from these cultures was used for inoculating sterilized solutions containing 1 per cent of a cold water extract of a soil rich in humus and 0.25 per cent of water glass.

By this means nitrifying organisms were obtained which were less sensitive than those obtained by Winogradsky in inorganic media. Four stable forms of nitric and 3 of nitrous bacteria were isolated. One of the nitric forms was capable of resisting the action of steam at 100° for 2 minutes, and one of the nitrous bacteria lived for 1 minute in steam at the same temperature. The other two nitrous bacteria could not withstand steam, but survived for several minutes in a dry

heat of 80 to 100° C. Nitric and nitrous bacteria grew in the same medium without interference, and inoculating material was prepared by drying previously sterilized calcareous soil to which both forms of nitrifying organisms had been added.

Pot experiments are reported in which grasses and cereals grown on sterilized sand, to which sterilized humus, ammonium sulphate, and minerals were added, were much benefited by inoculation with the nitrifying organisms.

The results obtained indicate that denitrification is hindered and loss of free nitrogen prevented by the presence of an abundance of nitrifying organisms. When, however, denitrifying organisms predominate, the action of the nitrifying bacteria is interfered with, especially if the supply of oxygen is limited.

On the nitrification of organic nitrogen, V. OMELIANSKI (*Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 13, pp. 473-490).—An account is given of various culture experiments, the results of which led to the conclusion that pure cultures of nitrifying bacteria are incapable of nitrifying organic nitrogen. Nitrogen in this form must first be converted into ammonia by the action of other nitro-organisms before the nitrifying organisms can utilize it. It is claimed that the opposite conclusions reached by Frankland, Warington, and Stutzer and his associates were based upon inaccurate observations.

Denitrification and fermentation, K. WOLFF (*Hyg. Rundschau*, 9 (1899), pp. 1169-1172; *abs. in Chem. Centbl.*, 1900, I, pp. 52, 53; *Jour. Chem. Soc. [London]*, 78 (1900), No. 450, II, p. 298).—In experiments with typhus-like bacilli, including *B. coli commatne* and others, and 2 hay bacilli, one apparently *B. fitzianus* from ginger root and the other from meal, it was found that while all the organisms reduced nitrates to nitrites in 1 per cent dextrose broth containing 0.05 to 0.23 per cent of potassium nitrate, the hay bacilli were much more active in this respect than the others, although only one of the bacilli can be compared with the real denitrifying organisms. The activity of the organisms was not affected by the strength of the sugar solution, but was decidedly influenced by the amount of nitrate present, an excess of the latter checking fermentation without otherwise disturbing the functions of the organisms. Complete disappearance of nitric nitrogen took place simultaneously with fermentation. The author concludes that denitrification is not due to the direct action of the organisms, but that the products of fermentation reduce nitrates to nitrites and eventually convert them into carbonates.

Recent investigations on the development of aromatic principles by alcoholic fermentation in the presence of certain leaves, G. JACQUEMIN (*Compt. Rend. Acad. Sci. Paris*, 128 (1899), No. 6, pp. 369-371).—In a previous number of this publication¹ the author

¹ *Compt. Rend. Acad. Sci. Paris*, 125 (1897), No. 2, p. 114.

has given an account of his investigations in which he claims the development of aromatic principles through the alcoholic fermentation of wine in the presence of the leaves of the apple, pear, or grape, producing the characteristic odor and flavor of the individual fruit. This, he says, is brought about by the splitting up of certain glucosids contained in the leaves through the action of a diastase secreted by the yeast used in the fermentation. Subsequent investigations have shown that the leaves of different varieties of grapes placed in the must give to the wine different flavors and bouquets. If instead of the leaves an extract containing the glucosids of the leaves be used in connection with the pure yeast, the same result is secured.

The author states that during the past season numerous experiments were carried on in different parts of France with both white and red wines which confirm his statement. One experiment is quoted in which the must of an ordinary red wine was pasteurized and divided into equal portions, one of which received an extract of the leaves from a St. Emillion grapevine which had been prepared by mixing them with a pure yeast 2 days before adding to the must; the second was given a pure yeast, while a third lot was allowed to ferment in the ordinary manner. The products of the fermentation were submitted to various experts. That resulting from the fermentation in the presence of the extract of the leaves was pronounced far superior to the others.

In conclusion the author claims that his experiments show that by the use of grape leaves from varieties of superior excellence, or of extracts containing the glucosids from these leaves, even in a quantity as small as 1:1000, the quality of the wine may be greatly improved.

Investigations concerning bacteria in the fermentation of tobacco, J. H. VERNHOUT (*Meded. S' Lands Plantentuin*, 34 (1899), pp. 49, pls. 2).—The author has investigated the fermentation of tobacco and concludes that (1) the fermentation of tobacco is due in whole or in part to the chemical action of bacteria, and (2) a thermophile bacterium plays an important rôle in the process of fermentation. In support of these conclusions he gives a detailed account of his work. Germs that could flourish at 50° C. were first isolated from tobacco leaves in which the process of fermentation had been completed. Two germs which he studied under the designations A and B were thus isolated. Inoculation experiments were made by cutting into small pieces or by folding tobacco leaves in which fermentation had just commenced. The pieces or folded leaves were placed in petri dishes and sterilized at 120° C. for 45 minutes to 1 hour, after which one dish was inoculated with a pure culture of germ A. Seven experiments are recorded, of which 1 gave positive results, 4 doubtful, and 2 negative. In the last-mentioned experiments fermentation took place equally well in the check and in the inoculated dish. Two

experiments were also made in which some dishes were sterilized while the check was left unsterilized. In both cases fermentation took place in the check but not in the sterilized dish.

One chapter is devoted to a description of germ A on different culture media. This germ is related to *Bacillus subtilis* and the author proposes for it the name *Bacillus tabaci-fermentationis*. Germ B is also described and said to belong to the genus *Bacterium*. The name *Bacterium tabaci-fermentationis* is proposed.—H. M. PIETERS.

On the chemical nature of enzymes, O. LOEW (*Science*, n. s., 10 (1899), No. 261, pp. 955-961).—The author states that enzymes may be physiologically classified into 3 groups, those which are intimately connected with nutrition, such as diastase, pepsin, trypsin, lipase; those causing oxidation, as the oxidases; and those producing coagulations, such as rennet, thrombase, and pectase.

In considering the chemical nature of enzymes, 3 important questions have received attention: (1) Are the enzymes proteins or not? (2) how is the fact to be explained that a very small amount of the enzymes can transform a relatively large amount of another compound? and (3) what is the cause of their specific action, that is, why can enzymes attack only a specific compound and not others closely related? The different investigations bearing upon these subjects are reviewed at some length. The author believes that the tendency on the part of some authors to infer from the nature of one enzyme the nature of all others is not justified. He believes there may exist enzymes in every group of proteins, and that there may be some that are not proteins but which are derived therefrom.

The action of small quantities of enzymes on large quantities of other substances is explained by the close connection existing between lability and activity, and further by the principle of intensity of energy by which their chemical energy may be transferred to other compounds. In explaining the specific action of enzymes, the principle of configuration of molecules comes in, and the closer the contact the more perfect transmission of energy is possible.

Report of the bacteriologist, H. H. LAMSON (*New Hampshire Sta. Bul.* 68, pp. 158-164, fig. 1).—A statement is made of the lines of work followed in the department of bacteriology during the year and a popular account is given of bacteria, their morphology, physiology, and relations to agriculture.

Bacteria and their place in systems of fungi, W. WINKLER (*Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), Nos. 16-17, pp. 569-579; 18-19, pp. 617-630, pls. 2).

The classification of bacteria, W. MIGULA (*System der Bakterien*. Jena: G. Fischer, 1900, vol. 2, pp. 1068, pls. 18, figs. 35).—A systematic classification of bacteria.

Bacteria as related to economy of nature, industrial processes, and public health, G. NEWMAN (*New York: G. P. Putnam's Sons; London: John Murray, 1899*, pp. 348; rev. in *Science*, n. ser., 11 (1900), No. 263, p. 70).

Micro-organisms useful in agriculture, F. CAVARA (*Bul. Soc. Bot. Ital.*, 1899, No. 7-8, pp. 241-243).

Bacteria in milk products and other food materials, BLOCH (*Berlin. Klin. Wehnschr.*, 37 (1900), No. 4, pp. 85, 86).—The author found numbers of bacterial colonies in cultures from plasmon, but an equally large number from nutrose and other milk products.

Contribution to the morphology of the organism described as *Bacterium radicola*, A. STUTZER (*Mitt. Landw. Inst. Breslau*, 1900, No. 3, pp. 57-71).

The influence of sunlight on bacteria, L. KEDZIOR (*Arch. Hyg.*, 36 (1899), No. 4, pp. 323-334).

Gypsum plates for the cultivation of nitrification bacteria, V. OMELIANSKI (*Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 18-19, pp. 652-655).

On the multiplication of yeasts without fermentation in presence of a limited quantity of air, A. ROSENTIEHL (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 4, pp. 195-198).

The length of generations in certain yeasts, D. P. HOYER (*Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 21, pp. 703-705).—A large number of species of yeast were studied and under the conditions of experiments the time elapsing between one generation and another determined. It ranged from 3.5 hours to about 10 hours, depending upon the temperature.

On the duration of the vitality of dried yeast, H. WILL (*Ztschr. Gesam. Brauw.*, 1899, No. 4, p. 43; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 14, p. 527).—Yeast is said to have grown readily after having been kept in a dried state for 12 years and 2 months.

Soluble ferments produced during germination of seeds having a corneous endosperm, E. BOURQUELOT and H. HÉRISSEY (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 1, pp. 42-44).

The oxy-ferments of milk and saliva, R. DUPOUY (*Jour. Pharm. et Chim.*, 6. ser., 8 (1898), pp. 551-553).

On the secretion of diastases, DIENERT (*Compt. Rend. Acad. Sci. Paris*, 129 (1899), No. 1, pp. 63, 64).

On the so-called indigo fermentation and new indigo plants, H. MOLISCH (*Sitzber. Math. Naturw. Cl. K. Akad. Wiss. [Vienna]*, 107 (1898), No. 7, pp. 747-776, pl. 1).

The action of formaldehyde on enzymes and certain proteids, C. L. BLISS and F. G. NOVY (*Jour. Expt. Med.*, 4 (1899), No. 1, pp. 47-80).

METEOROLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review*, 28 (1900), Nos. 1, pp. 1-48, charts 10; 2, pp. 51-93, pl. 1, figs. 5, charts 11; 3, pp. 95-139, charts 10).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts, these numbers contain the following articles and notes:

No. 1, a special contribution on Some of the results of the international cloud work for the United States, by F. H. Bigelow; and notes by the editor on wireless telegraphy, lightning rods, a kite and balloon station near Berlin, Germany, South African meteorology, frost work in South Africa, Prof. Henry Allen Hazen, winterkilling of fruit trees, farmers' bulletins, the soil and the crops, errors in school books, fruit protection in Florida, historical events in meteorology, irrigation in winter, the Weather Bureau and commerce on the Great Lakes, the high stations of Wyoming, winter thunderstorms in Mississippi, snowfall in the Rocky Mountains, the relation of temperature to color, Meteorological Congress at Paris, September 10-16, 1900.

meteorology at the Paris Exposition, lectures in the schools, long dry spells, lectures at farmers' institutes, climatology of San Diego, Cal., wind-roses for Oklahoma, Charles G. Boerner, artificial rain, and the weather maker.

No. 2, special contributions on Anemometer tests (illus.), by C. F. Marvin; Kite observations at Bayonne, N. J., by the Bayonne Kite Club; and notes by the editor on climatology of St. Kitts, lectures at farmers' institutes, a change at Kew observatory, the London meteorological office, maximum pressure of wind, and George James Symons.

No. 3, special contributions on Comparative thermometer readings at New York, by A. J. Henry; Loss of life in 1899 by lightning, by A. J. Henry; Hurricanes of 1895 and 1896 in the Philippine Archipelago, by F. O. Stetson; Notes on climate in the Philippines, by I. N. Brewer; A partial explanation of some of the principal ocean tides (illus.), by R. A. Harris; and notes by the editor on the measurement of radiant heat, the use of the divining rod in the search for water, tides in the ocean and the atmosphere, solar spots and terrestrial phenomena, the storms of March, 1888 and 1900, frost protection by hot water, the total eclipse of the sun May 28, 1900, stations of the Mexican Telegraph Company, influence of the wind and of rhythmic gusts on the level of Lake Erie, long balloon voyages, wireless telegraphy, storms of sleet, the cold waves of January and February, 1864, a Black River thaw, sudden disappearance of ice in the lakes, benefits and injuries due to storms, waterspout, objectionable meteorological terms, danger lines on gages and contour lines on city maps, the legal value of Weather Bureau records, and sudden temperature changes in Montana.

Maryland Weather Service (*Maryland Weather Service, 1 (1899)*, pp. 566, pls. 54, figs. 61).—This is the first of a proposed series of reports dealing with the climatic features of Maryland, including the physiography, meteorology, hydrography, medical climatology, agricultural soils, forestry, crop conditions, and flora and fauna of the State. The present volume is confined to a discussion of physiography and meteorology, and includes the following articles: Introduction, by W. B. Clark, explaining the establishment of the State weather service and the lines of investigations pursued; A general report on the physiography of Maryland, and The aims and methods of meteorological work, by C. Abbe; A sketch of the progress of meteorology in Maryland and Delaware, by O. L. Fassig; and An outline of the present knowledge of the meteorology and climatology of Maryland, by F. J. Walz.

A summary of the main results of meteorological observations in Maryland is as follows:

Normal annual temperature 53 to 54° F.; normal annual maximum 63°; normal annual minimum 45°; highest normal monthly temperature 75.5° in August; lowest normal monthly 31° in January; absolute maximum temperature for the State since 1891, 109° at Boettcherville in July, 1898; minimum for the State since 1891, -26 at Sunnyside in February, 1899; average date of last killing frost in spring April 5 to 15; first killing frost in fall October 5 to 15; advent of spring (average temperature 43.8°) March 7 in southern Maryland, April 1 in northern Maryland, and April 15 in northwestern Maryland; average barometric pressure for 28 years at Baltimore 30.7 in., highest 30.98 in., lowest 29 in.; normal annual precipitation (rain, melted snow, etc.) 43 in. (of this 23 to 24 in. falls in the spring and summer and 19 to 20 in. in fall and winter); rainy days 168; cloudiness 50 to 60 per cent; average humidity 68 per cent; direction of the wind northwest in winter, south and southwest in summer.

Meteorology, C. H. PETTEE (*New Hampshire Sta. Bul. 68, pp. 164, 165, 168-192*).—This gives brief notes on additions to equipment of the meteorological department and on the weather of the year, and a monthly and annual summary for the period from July, 1898, to June, 1899, inclusive, of observations at Durham, N. H., on temperature, precipitation, cloudiness, and prevailing winds. The mean temperature for the year was 45.9°, for 4 years ending June 30, 1899, 45.8°; total precipitation for the year 43.6 in., average for 4 years 45.5; snowfall 82 in., average for 4 years 67; number of days on which there was precipitation of 0.01 of an inch during 1898 to 1899, 107, average for 4 years 105; prevailing direction of the wind, northwest; clear days 114, partly cloudy days 161, cloudy days 80.

"The last 3 months of the year [1898-99] were abnormally dry, with a total precipitation of only 3.6 in. Indeed this lack of rain was the chief feature of the weather for the year, and had a marked effect upon farm crops, especially grass, the amount of hay harvested in this vicinity being about one-half of that of the previous year. Hoed crops on heavy soil did not suffer seriously."

Meteorological summary for Ohio, 1898, C. A. PATTON (*Ohio Sta. Bul. 109, pp. 373-386*).—Notes on the weather and tabulated daily and monthly summaries of observations at the station on temperature, precipitation, cloudiness, direction of the wind, etc., are given, and for comparison similar data for previous years and for other parts of the State. The following is a summary of results:

Summary of meteorological observations in Ohio.

	For the experiment station.		For the State.	
	1898.	Average for 11 years.	1898.	Average for 16 years.
Temperature (°F.):				
Mean	50.4	49.0	52.0	50.7
Highest	(July 3) 96	(Aug. 8, 1891) 99	(July 1) 105	(July 4, 1897) 113
Lowest	(Feb. 2) -9	(Jan. 20, 1892) -20	(Feb. 3) -20	(Jan. 25, 1884) -34
Range	105	119	125	117.1
Mean daily range ..	20.3	20.3		
Greatest daily range.	(Nov. 14) 50	(Oct. 6, 1895) 55		
Least daily range ..	{ (Jan. 21, Mar. 1) 5 2, Dec. 18. }	(Feb. 6, 1897) 0		
Clear days	133	120	130	118
Fair days	104	122	110	122.5
Cloudy days	128	118	125	124.7
Days rain fell	134	126	121	123.6
Rainfall (in.):				
Greatest monthly ..	(July) 6.79	(July, 1896) 8.05		
Least monthly	(Sept.) 2.15	(Sept., 1897) .29		
Mean yearly	47.85	39.75	43.78	37.85
Prevailing direction of wind.	N-SW.	SW.	SW.	SW.

Relations between the annual variations of temperature and the successive phases of vegetation, A. DESMOULINS (*Ann. École Nat. Agr. Montpellier, 11 (1899-1900), pp. 9-51*).—This is a very full discussion of this subject, based upon observations by the author and others at Montpellier, and by other investigators in different parts of

France, and includes (1) the duration of the stages of growth of different plants and their relation to temperature, and (2) the sums of temperature necessary for the maturing of different plants. The different stages of plant growth from seeding to harvest are treated in detail. The main results of observations at Montpellier are summarized in the following table:

Stages of growth and sums of temperature required for the maturing of different plants.

	Date of planting.	Time required for—				Sums of temperature required for growth and maturity.
		Germi- nation.	Head- ing.	Bloom- ing.	Matu- rity.	
		Days.	Days.	Days.	Days.	Deg. C.
Wheat (Noé)	End of October or begin- ning of November.	13	195	199	237	2398
Spring wheat	March 15	16	91	96	124	1760
Rye	End of October or begin- ning of November.	14	174	188	230	2240
Barley	do	14	185	190	223	2100
Winter oats	do	14	201	205	231	2220
Corn (from the Landes)	April 10	15	80	150	2730
Corn (Caragua)	do	14	110	167
Corn (Cinquantin)	do	13	86	136
Sorghum (saccharine)	April 1	18	120	165	2894
Buckwheat	do	7	29	136
Flax	March 3	15	63	105	1555
Beans (haricot)	April 15	15	49	89	1611
Beets	March 15	22	11	205	3470
Jerusalem artichokes	Beginning of March	37	191	221	3665
Potatoes	do	37	92	135	2287

a Calculated according to the Hervé-Mangon method from the sums of the daily temperatures (average of the maxima and minima) received by the plant from the time of planting to the time of harvest, discarding all average temperatures below those required for the growth of plants, *i. e.*, 6° C. for wheat, 9° for corn, etc.

Meteorological observations at Michigan Agricultural Experiment Station for the year 1898, R. C. KEDZIE (*Michigan Sta. Rpt. 1899, pp. 79-103*).—Tabulated daily and monthly summaries of observations during 1898 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

The summary for the year is as follows: Mean temperature, 48.17° F.; humidity, 89.6 per cent; atmospheric pressure (reduced to 32° F.), 29.12 in.; cloudiness, 48 per cent; amount of rain or melted snow, 31.72 in.; snowfall, 44.25 in.; number of thunderstorms, 10.

Meteorological observations, W. B. ALWOOD (*Virginia Sta. Rpt. 1899, p. 10*).—A tabulated monthly summary is given of observations at Blacksburg, Va., during the year ended June 30, 1899, on temperature, precipitation, snowfall, and cloudiness, and for 7 years (1893-1899) on temperature and rainfall. The mean temperature of the year ended June 30, 1899, was 50.8° F., the rainfall 50.9 in.; average temperature for 7 years was 51.7°, and rainfall 37.78 in.

Meteorological summary for the year 1899, H. DUFOUR and D. VALET (*Chron. Agr. Canton Vaud, 13 (1900), No. 7, pp. 149-152*).—This is a summary of observations on temperature, precipitation, sunshine, and temperature of the soil at the Agricultural Institute at Lausanne.

A comparative study of variations in temperature and of rainfall at Aigoual and Montpellier, F. HOUDAILLE (*Ann. École Nat. Agr. Montpellier, 11 (1899-1900), pp. 52-97, figs. 7, charts 12*).—Comparative observations during 3 years (1896-1898) at these two points, one in the Pyrenees, the other in the plain, 65 kilometers apart and differing in altitude by 1,525 meters, are reported and discussed.

Numerous correlations between both temperature variations and rainfall at the two places are shown. The utilization of observations at the more elevated point in local forecasts is explained.

The diurnal range of rain at the seven observatories in connection with the meteorological office, Great Britain, 1871-1890, R. H. SCOTT (*London: Darling & Son, Ltd., 1900, pp. 48*).

A severe sleet storm, H. VON SCHRENK (*Trans. Acad. Sci. St. Louis, 10 (1900), No. 5, pp. 143-150, pls. 2*).—An account is given of a sleet storm of unusual severity which occurred February 27, 1900, over a large tract of country, including parts of Missouri, Illinois, Indiana, and Ohio.

Prevention of hailstorms by the use of cannon, J. M. PERENTER (*Nat. Geogr. Mag., 11 (1900), No. 6, pp. 239-241*).

The average and maximum velocity of the wind at Montpellier, F. HOUDAILLE (*Ann. École Nat. Agr. Montpellier, 11 (1899-1900), pp. 98-110, figs. 3, charts 12*).—The methods and apparatus used are described and the results obtained during 1898 reported.

Frost and hot water protection (*California Fruit Grower, 25 (1900), No. 613, p. 1*).—This is an account of an experiment at Riverside, Cal., in which water was heated to 85° in a tubular boiler and allowed to flow through the irrigating ditches between the rows of trees. A short distance from the ditches the temperature was 36° while the normal was 32° or freezing temperature.

Artificial clouds as a means of protection against frost, F. SISGNE (*Prog. Agr. et Vit., 17 (1900), No. 12, pp. 322-325*).—A popular article.

The applications of meteorology to agriculture, J. VANDERVAEREN (*Rev. Gén. Agron. Louvain, 9 (1900), Nos. 2, pp. 60-70; 3, pp. 102, 103, pl. 1; 4, pp. 156-162*).—A general article.

The telegraphic weather service for German agriculture (*Mitt. Deut. Landw. Gesell., 15 (1900), No. 16, pp. 104-106*).

The periods of plant growth and the effects of climatic conditions on plants, A. DESMOULINS (*Ann. École Nat. Agr. Montpellier, 11 (1899-1900), pp. 5-8*).—A continuation of observations of previous years (E. S. R., 9, p. 1035).

WATER—SOILS.

The fruit soils of Virginia, W. B. ALWOOD (*Virginia Sta. Bul. 98, pp. 29-41, map 1*).—This is a compilation of available information on this subject, including the author's observations, and deals mainly with the economic phases of the question. In discussing the subject the State is divided into 6 natural divisions, viz: Tidewater, middle Virginia, Piedmont, the Blue Ridge section, the valley, and Appalachia. A map showing the extent of these different divisions, and the location of areas known to be adapted to pippin orchards, accompanies the article. "It is hoped that this publication will mark the beginning in the near future of a more critical study of certain phases of this all-important subject to fruit growers."

Analyses of soils, C. F. JURITZ (*Agr. Jour. Cape Good Hope, 16 (1900), No. 5, pp. 271-288*).—In continuation of the soil survey of Cape of Good Hope, previously referred to (E. S. R., 11, p. 823), the author collected and analyzed 60 samples of soil at different points in the George, Knysna, Uniondale, and Oudtshoorn Divisions of the

Province. Descriptions and analyses of these samples, with a discussion of their comparative agricultural value, are given. The average composition of the soils examined is as follows:

Average composition of western Cape of Good Hope soils.

Division.	Number of analyses.	Fine earth (passing $\frac{1}{8}$ mm. sieve).	In fine earth.			Nitrogen. ^a
			Lime.	Potash.	Phosphoric acid.	
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
George.....	16	81.0	0.040	0.055	0.047	0.157
Knysna.....	13	87.6	.100	.035	.041	.213
Uniondale.....	12	69.2	.057	.099	.064	.135
Oudtshoorn.....	19	79.0	.678	.145	.091	.131

^a In soil passing 1 mm. sieve.

"The soils of the George district are, generally speaking, poor in lime and phosphates, and on the whole contain a fair amount of potash, while they are rich in nitrogen. The Knysna soils contain an even larger percentage of nitrogenous material, but are poor in potash and phosphoric oxid, lime being little better. Coming to Uniondale, there is also a general lack of lime, but potash and phosphates are present in fair quantity, together with a good percentage of nitrogen. The Oudtshoorn division shows a good quantity of lime and nitrogenous matter in the soil, and is also fairly satisfactory as regards potash and phosphoric oxid."

The behavior of water-soluble phosphoric acid in the soil, M. ULLMANN (*Abs. in Chem. Ztg.*, 24 (1900), No. 20, *Repert.*, p. 65; *Chem. Centbl.*, 1900, I, No. 15, p. 830).—In experiments on this subject it was found that the phosphoric acid of superphosphate applied as a top-dressing circulated in the soil, but remained soluble in water for months after application. The rapidity of reversion of course depends upon the amount of lime, magnesia, iron oxid, alumina, etc., present, but according to the author the rate of reversion in artificial soil mixtures may be misleading as to this action in natural soils.

Cultivation and weeding, P. P. DEHÉRAIN (*Ann. Agron.*, 26 (1900), No. 5, pp. 257-261).—Pot and field experiments made by the author showed no benefits resulting from the cultivation of bare soil as regards moisture preservation by the formation of a top soil mulch. Irrigated soils in vetch contained considerably larger percentages of soil moisture than unirrigated soils in vetch, but both soils showed from 25 to 50 per cent less moisture than soils on which no plants whatever were growing. Weeds allowed to grow in crops have an effect similar to the vetch in evaporating soil moisture. The author believes the results of his experiments show that "cultivation" and "weeding" are words of equal value, both being beneficial in preserving soil moisture in so far as they destroy weeds.

A new method for the mechanical analysis of soils, G. SCARLATA (*Staz. Sper. Agr. Ital.*, 32 (1899), pp. 634-637; *abs. in Chem. Centbl.*, 1900, I, No. 10, p. 571).—The apparatus used in the proposed method consists of a narrow 500 cc. beaker having a siphon with stopcock on

one side and a tube with stopcock communicating with a water reservoir on the other. Five grams of soil is placed in the beaker, acidified with hydrochloric acid, and water added to within 2 cm. of the rim of the beaker. By careful heating and stirring the lighter clay particles are carried off through the siphon by means of a current of water which is made to flow through the beaker. This operation is repeated until the water passing off from the beaker becomes clear and remains clear when the contents of the beaker are heated to boiling. The method was compared with that of Schloesing, and it is claimed that it is fully as accurate and requires less time.

Pollution of natural waters and of cultivated soils by the products of gas factories, A. LEMOINE (*L'Ing. Agr. Gembloux*, 10 (1900), No. 9, pp. 559-572).—This is mainly a review of investigations on the composition of the by-products (gas lime and gas liquor) of gas making and on their action on soils and natural waters.

The kaolinizing action of roots on feldspar, F. SESTINI (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, pp. 147-153).—The author concludes that the formation of the clay of soils is not entirely due to the natural agencies to which it has heretofore been attributed, but is in part due to the decomposing action of roots and of numerous minute organisms which are found in the soil.

Some Queensland soils, J. C. BRÜNNICH (*Queensland Agr. Jour.*, 6 (1900), No. 5, pp. 403-418).—Mechanical and chemical analyses are reported of 21 samples of soil (with subsoil) from different parts of the various state farms of the Province. The soils examined are described and their reaction, weight, capacity for water, and capillary power are also stated.

Report of the geologist, E. H. BARBOUR (*Rpt. Nebraska State Bd. Agr.* 1898, pp. 287-320, figs. 87).—Mechanical analyses of 85 samples of Nebraska subsoils in continuation of previous work (E. S. R., 9, p. 737) are reported. These analyses were made by the Division of Soils of the U. S. Department of Agriculture.

FERTILIZERS.

Denitrification and the decomposition of animal excrement in the soil, C. ROGOYSKI (*Ann. Agron.*, 26 (1900), No. 3, pp. 121-140).—Previous work on this subject is briefly reviewed and laboratory experiments with small amounts of various mixtures of soil (200 to 233 gm.), horse manure (40 to 41 gm.), urine (10 cc.), straw (11 gm.), and nitrate of soda (0.9 to 9 gm.) are reported. The changes which the nitrogen underwent from January 21 to June 19 and from May 13 to July 5 are recorded. The author concludes from the results that in the presence of a large amount of manure there was denitrification of the nitrates, the liberated nitrogen either escaping in the free state or being converted partially or completely into insoluble compounds. The same changes occurred when soil containing large quantities of manure or straw was fertilized with urine (or ammonia salts). The insoluble nitrogen compounds formed under these circumstances seemed to be readily nitrifiable.

The above changes did not occur when manure was added in amounts usually employed in practice, or even when added in considerably larger amounts than are usually applied, but only when excessive amounts were used. When excessive amounts are not used the author claims that the nitrates are not decomposed and the urine is nitrified.

Ground bone compared with superphosphate and Thomas phosphate as sources of phosphoric acid, U. J. MANSOLT (*Orgaan Ver. Oudleer. Rijks. Landbouwschool*, 12 (1900), No. 143, pp. 108, 109).—Notwithstanding the claims of investigators that ground bone is inferior to other sources of phosphoric acid for fertilizers, the former remains popular with farmers, especially in England. The author thought it desirable that field experiments extending over more than one year should be undertaken in order to determine the effect of the bone meal during the second year. For such an experiment a piece of sandy loam was selected and divided into 10 parts, each 50 square meters in size. The entire field was fertilized with 250 kg. of sulphate of ammonia (20 per cent nitrogen) per hectare and 200 kg. of sulphate of potash (50 per cent K_2O) per hectare, in order to insure the presence of an abundance of nitrogen and potash. In the spring of 1898 the whole field received nitrate of soda at the rate of 300 kg. per hectare. Two of the plats received no phosphate, while to the others were applied superphosphate, Thomas slag, bone meal with the fat removed, and bone meal with the gelatin removed. In each case enough of the phosphatic fertilizer was used to make 100 kg. of phosphoric acid per hectare.

Rye was planted on all the plats in November, 1897, and in the spring of 1898 the stand was very satisfactory. The rye was harvested in August, 1898, and peas planted for the following crop. For this crop no fertilizers were used. The increase in grain for the plats receiving phosphates over those receiving no phosphates was for the 2 years as follows:

Increase in yield due to different phosphates.

	Rye.	Peas.
	Kg.	Kg.
Superphosphates.....	475	950
Thomas phosphates.....	600	550
Bone meal (fat removed).....	375	1,250
Bone meal (gelatin removed).....	750	1,600

In every case the results showed that on light soils the bone meal is in the long run equal at least to superphosphate and Thomas slag.—H. M. PIETERS.

Introduction to field experiments with fertilizers, A. L. KNISELY (*New York Cornell Sta. Bul.* 179, pp. 285–318, figs. 8).—This bulletin gives the plan and object of cooperative field experiments with fertilizers commenced under State appropriation in 1897. During the 3

years experiments have been made on 371 different farms in the State. The general results of this work are briefly discussed and the character of the work is illustrated by accounts of a few of the experiments made.

"A study of all the experiments for 3 years recorded shows that of the 3 plant foods, when used alone, nitrogen gave the largest increased yield in 26 experiments, phosphoric acid in 58 experiments, and potash in 36 experiments. This would seem to indicate that when one plant food is used alone, phosphoric acid will in most cases give the best results. When a mixture of 2 plant foods was applied, nitrogen and potash gave best results in 24 experiments, phosphoric acid and potash in 48 experiments, and nitrogen and phosphoric acid in 52 experiments. A comparison of a complete fertilizer and stable manure shows in 38 experiments the complete fertilizer gave better results, while in 54 cases stable manure produced the larger crops. These good results accompanying the use of stable manure may not be due so much to the plant food it contains as to an improvement in the physical conditions of the soil.

"In only 40 cases out of a total of 126 recorded did the complete fertilizer, a mixture of nitrate of soda, phosphate and muriate of potash, give better results than fertilizers containing one or two of the plant foods.

"These results tend to show that more often it is some especially prepared rather than a complete fertilizer that a soil requires, and that when a farmer uses commercial fertilizers he is often not following the wisest policy; he is simply 'going it blind' and possibly throwing away money."

Field tests with fertilizers on heavy clay lands, H. A. HUSTON (*Indiana Sta. Bul. 81, pp. 77-92.*)—This is an account of fertilizer experiments on tenth-acre or twentieth-acre plats on 3 farms in the State, 2 in Orange County and 1 in Monroe County. In the first two cases the soil was oak clay resting on red clay subsoil, and in the third case the soil was cold, badly drained upland clay. Mechanical analyses of one of the Orange County soils, the Monroe County soil, and the soil of the experiment station farm at Lafayette, a dark, productive loam, are given. Corn was grown on all of the farms in 1896. The fertilizers used were nitrate of soda, 60 lbs. per acre; muriate of potash, 60 and 120 lbs., and dissolved boneblack, 230 and 250 lbs., 2 by 2 and all 3 combined; and on 1 plat in each experiment (except one) lime (1,400 and 2,800 lbs. per acre) was used in addition to the complete fertilizer. Wheat followed corn on 2 of the farms (one in Orange County and the other in Monroe County). The fertilizers used on the wheat were nitrate of soda, 74 and 148 lbs. per acre; dissolved boneblack, 124 and 248 lbs.; muriate of potash, 24 and 46 lbs., and lime, 2,800 lbs. In addition to these fertilizers, bone alone, at the rate of 200 lbs. per acre, broadcast and drilled in, and acidulated bone acid phosphate, raw bone, and steamed bone, combined with dried blood and potash, were used in the experiments in Monroe County.

The yields of the crops with the different fertilizers are reported, and the results are discussed "as illustrating how such a test may be conducted." "On all 3 farms a mixture of acid phosphate and muriate of potash in the proportion of 4 lbs. of phosphate to 1 of muriate gives

practically as good results as a mixture containing nitrate of soda in addition to these." In one experiment phosphoric acid and nitrogen appeared to be the fertilizing constituents most needed for wheat. The results of the other wheat experiment were inconclusive. Lime was in general beneficial.

The maintenance of fertility, C. E. THORNE (*Ohio Sta. Bul. 110*, pp. 91, pls. 11, *dgms.* 8).—This is a detailed account of field experiments with fertilizers carried on by the station from 1888 to 1899. These experiments have been reported on from time to time in the reports and bulletins of the station (E. S. R., 10, p. 949).

Nearly 900 permanent plats, mainly one-tenth acre in size, have been used. The work has been conducted at 5 different points in Ohio, viz, (1) at the experiment station at Wooster, where the soil is a yellow and somewhat sandy clay of glacial drift origin but largely modified by the soft sandy shales upon which it lies; (2) on the farm of the Ohio State University at Columbus, where the soil is a much heavier clay than that at Wooster, lying in part upon the Huron shale and in part upon alluvial gravels; (3) near East Liverpool, Columbiana County, on a thin clay underlaid by porous shale; (4) at the substation at Neapolis, about 20 miles west of Toledo, on the yellow dune sands which mark the ancient beach of Lake Erie, and (5) at a substation near Strongsville, about 12 miles southwest of Cleveland, on a cold, heavy, tenacious, white clay, underlaid by an impervious argillaceous shale (Cuyahoga shale). Mechanical and chemical analyses of 4 of these soils are reported, the mechanical structure being shown graphically. The fertilizers used have included dissolved boneblack and South Carolina and Tennessee acid phosphate, wheat bran, phosphatic slag, and bone meal being also used to some extent as sources of phosphoric acid; nitrate of soda, sulphate of ammonia, dried blood, tankage, linseed meal, muriate of potash, and barnyard manure.

"The crops employed in these tests are corn, oats, wheat, clover, timothy, and potatoes, soy beans being sometimes substituted for clover in case of failure to secure a stand of the latter crop. The cereal crops—corn, oats, and wheat—are grown both continuously and in rotation. Three rotations are in progress, one of corn, oats, and wheat, 1 year each, followed by clover and timothy, 2 years; one of potatoes, wheat, and clover, 1 year each; and one of corn, wheat, and clover, 1 year each. The fertilizers are applied altogether upon the cereal and potato crops; the clover and timothy follow as gleaners."

To secure uniformity, machinery is used wherever possible for planting, distributing fertilizer, cultivating, harvesting, etc.

The following summary of results of these experiments is given:

"On soils formed chiefly from the argillaceous shales of the Waverly series phosphoric acid is found to be the constituent of fertility first required by corn, oats, wheat, and potatoes; but the maximum yield has not been obtained until both nitrogen and potash were also added.

"When used alone, or in combination with each other only, nitrogen and potash have produced but a very small increase, and have always been thus used at a heavy financial loss.

"The complete fertilizer, containing all three constituents, has produced a much larger total increase than the sum of the increase produced by the constituents used separately.

"When the cereal crops have been grown continuously on the same land the maximum increase of crop per pound of fertilizing constituents applied has been obtained when these constituents were used in approximately the same ratio to each other in which they are found in the crop; but the total recovery of fertilizing constituents in increase of crop, under continuous cropping, has never exceeded 60 per cent of the quantity applied in the fertilizer.

"When the cereals have been grown in rotation with clover the recovery of nitrogen has, under favorable conditions, exceeded the amount applied in the fertilizer; but even under these conditions the recovery of phosphoric acid and potash has remained far below the quantity applied in the fertilizer, when maximum yields were reached.

"Thus far in these experiments the surplus nitrogen accumulated by a crop of clover, the roots only being left in the ground, has not been more than sufficient to satisfy the demands of the one crop immediately following the clover.

"At the prices at which mixed fertilizers are sold in Ohio the attempt to furnish all the nitrogen as well as all the phosphoric acid and potash required to produce increase in cereal crops grown in continuous culture, has invariably resulted in pecuniary loss, although very large increase of crop has been thus produced.

"The rotation of cereals with nitrogen-gathering crops, therefore, has been shown to be absolutely essential to the profitable use of commercial fertilizers in any form.

"The increase of crop per pound of fertilizing constituents applied has generally been smaller when barnyard manure was used as the carrier of fertility than when chemical carriers were used; but the lower cost of barnyard manure has made it possible to use this material with profit when the use of commercial fertilizers resulted in loss.

"A marked superiority is indicated from manure which has been kept under cover until required for use over that which has been exposed, even for but a short time, in an open barnyard, and it seems possible to materially increase the effectiveness of manure by treating it with nitrogen-fixing materials.

"Nitrate of soda has shown itself to be the most effective of the carriers of nitrogen employed in these experiments, with sulphate of ammonia, dried blood and linseed-oil meal following in the order named.

"Of the four carriers of phosphoric acid used, basic slag and dissolved boneblack show the highest effectiveness, with raw bone meal and acid phosphate not far below.

"The tendency to excessive production of straw in wheat and oats is apparently due in part to climatic and in part to soil conditions, and the remedy apparently lies in systematic rotation, combined with judicious selection and distribution of fertilizing materials."

Commercial fertilizers, S. W. JOHNSON, E. H. JENKINS, ET AL. (*Connecticut State Sta. Rpt. 1899, pt. 1, pp. 92*).—This includes a statement of fertilizer sales in Connecticut in 1899, the text and an abstract of the State laws relating to fertilizers, a list of manufacturers complying with the laws, notes on the sampling and collecting of fertilizers, explanations concerning the analysis and valuation of fertilizers, a review of the fertilizer market for the year ended October 31, 1899,

and tabulated analyses and valuations of 459 samples of fertilizing materials, including nitrate of soda, dried blood, cotton-seed meal, castor pomace, dry ground fish, tankage, bone, dissolved boneblack, dissolved rock phosphate, sulphate of potash, sulphate of potash and magnesia, muriate of potash, kainit, cotton-hull ashes, wood ashes, and home-mixed and factory-mixed compound fertilizers.

In 8 samples of nitrate of soda examined the nitrogen ranged from 15.52 to 16 per cent. The cost of the nitrogen per pound varied from 12.6 to 14.5 cts., averaging 13.9 cts., "a fraction of a cent higher than in the previous year." The 1 sample of dried blood examined contained 13.68 per cent of nitrogen, the nitrogen costing 13.1 cts. per pound. In 32 samples of cotton-seed meal the percentage of nitrogen ranged from 6.72 to 7.63, averaging 7.14, and the price per pound of nitrogen from 11.9 to 14.6 cts., averaging 12.9 cts., "nearly a cent and a half per pound more than last year, but still the cheapest form of quickly available organic nitrogen in our market." Seven samples of castor pomace were examined. In these the percentage of nitrogen ranged from 5 to 6.19, and the price per pound of nitrogen from 13.5 to 16.3 cts. This "is the most expensive form of organic nitrogen in the market."

The cost of available phosphoric acid in the 5 samples of dissolved boneblack analyzed ranged from 5.9 to 7 cts. per pound, averaging 6.58 cts. In 8 samples of dissolved rock phosphate the cost of available phosphoric acid ranged from 3.7 to 6.1 cts. per pound, the average being 4.6 cts.

The cost of potash in 2 samples of high-grade sulphate was about 5 cts. per pound. In 3 samples of low-grade or double sulphate of potash and magnesia the cost ranged from 5.2 to 5.9 cts. per pound. "In 7 samples of muriate of potash the cost per pound of potash ranged from 3.8 to 4.9 cts., and averaged 4.2 cts., this being the cheapest source of water-soluble potash in the market. The cost of potash in the 1 sample of kainit examined was 5.1 cts. per pound."

"Of the 117 analyses of nitrogenous superphosphates, 18 were below the manufacturer's minimum guarantee in respect of 1 ingredient and 10 in respect of 2 ingredients. Nearly one-fourth of the whole number therefore failed in some respect to come up to the claims of the manufacturer. It should be said, however, that a deficiency of 1 ingredient was sometimes attended with a marked excess of another. . . . The average cost of the nitrogenous superphosphates was \$29.54; the average valuation was \$19.55, and the percentage difference 51.1. . . .

"Of the 108 samples [of special manures] analyzed, 21 did not fulfill the manufacturer's minimum guarantee in respect of 1 ingredient, and 9 were each deficient in respect of 2 ingredients. Six were deficient in nitrogen, 24 in potash, and 9 in phosphoric acid. The average cost per ton of the 108 samples examined was \$32.64, the valuation \$21.76, and the percentage difference 50. . . .

"The average cost of the bone manures [31 samples] was \$29.84 per ton; the average valuation, \$22.36; showing that the station valuation was lower than was justified by the average selling price of ground raw bone in Connecticut. It must, however,

be remembered that boiled and steamed bone, quite finely ground, are put on our Connecticut market by large manufacturing establishments at prices much lower than can be quoted by our small local manufacturers for ground raw bone."

In 36 samples of cotton-hull ashes the highest percentage of water-soluble potash found was 30.94, the lowest 11.1, and the average 22.62. "Allowing $4\frac{1}{2}$, 4, and 2 cts. per pound, respectively, for water-soluble, citrate-soluble, and insoluble phosphoric acid, the water-soluble potash cost from 4.2 cts. to 7.3 cts. per pound, or 6.7 cts. per pound on the average—a little less than in the previous year (7.1)."

The total and water-soluble potash were determined in 7 samples of cotton-hull ashes, with the following results:

Water-soluble and total potash in cotton-hull ashes.

Station No.	Water-soluble potash.	Total potash.	Potash insoluble in water.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
12444	24.34	26.92	2.58
12381	21.98	25.02	3.04
12187	21.18	24.20	3.02
12358	19.70	22.20	2.50
12319	22.90	24.18	1.28
12185	19.14	22.48	3.34
12317	20.58	25.82	5.24

Eleven samples of unleached ashes and 1 sample of leached ashes were examined. The unleached ashes included 8 samples of "Canada ashes" in which the average per cent of water-soluble potash was 4.63, of phosphoric acid 1.54, and lime 33.57.

The production of the Stassfurt deposits in 1899, MAIZIÈRES (*L'Engrais*, 15 (1900), No. 23, pp. 540, 541).—The production in 1899 is given as follows (in tons of 2,200 lbs.):

Production of Stassfurt potash salts in 1899.

	Tons.
Potassium chlorid (80 per cent)	167,432
Potassium sulphate (90 per cent)	24,655
Double sulphate of potassium and magnesium (48 per cent) ..	8,459
Potash salts for use only as fertilizers	67,481
Kainit	1,032,506
Carnalite	63,287

The consumption of potash salts in 1899 exceeded that of the previous year by 22,000 tons of actual potash.

Commercial fertilizers, M. A. SCOVELL, A. M. PETER, and H. E. CURTIS (*Kentucky Sta. Bul.* 85, pp. 79-129).—A brief account is given of the inspection of fertilizers in Kentucky during the year 1899, with a list of fertilizer dealers complying with the law, and analyses and valuations of 406 samples of fertilizers.

"The results of the analyses show that of the 406 samples analyzed, 94, representing 56 brands and 24 firms, fell so far below the guaranteed analyses of the manufacturers in phosphoric acid, nitrogen, or potash, or any two or all three of these constituents, as to be unaccounted for by variations in sampling or analysis."

Analyses of commercial fertilizers, W. C. STUBBS (*Louisiana Sta. Bul.* 58, pp. 189-264).—This bulletin gives the text of the State fertilizer law; discusses the vari-

ous commercial sources of nitrogen, phosphoric acid, and potash, and the valuation of fertilizers; and reports analyses of 528 samples of fertilizing materials, including, besides various mixed fertilizers, acid phosphate, cotton-seed meal, tankage, dried blood, ammonium sulphate, nitrate of soda, bone meal, kainit, sulphate of potash, potassium carbonate, muriate of potash, and silicate of potash.

The treatment of dead animals and abattoir refuse with sulphuric acid, A. PAGNOUL (*L'Engrais*, 15 (1900), No. 25, pp. 589-591).—The process first described by Müntz and Girard¹ is discussed with reference to its sanitary value and as a means of preserving a large amount of valuable fertilizing material which now goes to waste.

Results of fertilizer experiments with sulphate of ammonia, KLOEPFER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 10, pp. 376-384, figs. 3; 11, pp. 396-406, figs. 3; 12, pp. 436-445, figs. 2).—For notes on previous articles by the author on this subject see E. S. R., 10, pp. 533, 848.

Fertilizer experiments with sulphate of ammonia and nitrate of soda, KRAUS (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 6, pp. 232-237; 7, pp. 256-259).—In 2 years' experiments with barley grown on loam soils, sulphate of ammonia and nitrate of soda gave the same increase when applied at the same time (incorporated in the soil or applied as a top-dressing at time of planting), but when the nitrate was applied at a later date it gave a greater increase than the earlier application of sulphate of ammonia.

The nitrate of soda industry in Chile, W. NEWTON (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 5, pp. 408-417, figs. 8).—This article describes the region in which the nitrate is found; discusses the causes of its formation, its composition, exploitation, and preparation for the market; and gives statistics of exportations. The exportations amounted to 1,355,360 tons in 1899, as against 1,003,340 in 1890.

Lime and its uses in agriculture, A. P. AITKEN (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 2, pp. 87-98).—A study of the action of lime in the soil and as a factor in plant growth.

The ashes of olive residues and their fertilizing value A. DEVARDA (*L'Engrais*, 15 (1900), No. 22, pp. 516, 517).

On the reversion of phosphates and notes on improvements in the fertilizer industry, W. PAYSAN (*Chem. Ztg.*, 24 (1900), No. 18, pp. 185, 186).—Examinations of superphosphate made from Tennessee phosphate containing 79 per cent of calcium phosphate, 2.36 per cent of iron oxid, and 2.24 per cent of alumina, showed that there was practically no reversion of the phosphoric acid from the time that the superphosphate was prepared (September 2) to the time of the last examination (January 17).

On the question of the reversion of phosphates and remarks on recent progress in the fertilizer industry, VON GRUEBER (*Chem. Ztg.*, 24 (1900), No. 22, pp. 227, 228).—This article consists mainly of comments on the above article by Paysan.

The reversion of water-soluble phosphoric acid in superphosphates, C. ELSCHNER (*Chem. Ztg.*, 24 (1900), No. 24, p. 252).—Remarks on the above articles by Paysan and von Grueber. The author claims that sesquioxids combined with phosphoric acid cause reversion in superphosphates only when present in very large amounts and when the superphosphate is quickly dried. A very rapid reversion occurs, however, when the oxids are combined with silica. It is therefore combined silica and not oxids of iron and alumina which should be guarded against in the selection of phosphates for the manufacture of superphosphates.

Observations on the reversion of superphosphates, KLIPPERT (*Chem. Ztg.*, 24 (1900), No. 25, pp. 265, 266).—Remarks on the above articles.

¹Les Engrais, vol. 2, p. 234.

FIELD CROPS.

The influence of distance on the growth and chemical composition of plants, C. VON SEELHORST and PANAOTOVIC (*Jour. Landw.*, 47 (1899), No. 4, pp. 379-389).—The known effect of distance between sugar beets on their composition suggested a similar study of other plants. Oats and spring wheat were used. One, five, and eight plants, respectively, were grown in pots and observations made on the development and composition of each lot. A decrease of the ground space allotted to each plant increased the number of internodes and lessened the thickness of the culm, but increased its length. The uppermost internode was relatively and absolutely shorter, but the lowermost was longer as the thickness of the plants was increased. The length and weight of the head and the weight of the grain decreased with the reduction of ground space per plant. The spread, however, of the head increased.

The most striking change in composition was in the nitrogen content. Representing the nitrogen content of oat plants grown 1 in a pot by 100 per cent, the content of those grown 5 in a pot was 80.5 per cent, and when grown 8 in a pot, 70.1 per cent. The change in content of total ash, phosphoric acid, potash, and lime was not so great, but was nevertheless very marked.

The nutritive value of plants grown 5 in a pot was furthermore only 85.42 per cent as great as when grown 1 in a pot, and when grown 8 in a pot the nutritive value was only 76.91 per cent. The proportion of straw to grain was also increased as the distance between plants was decreased, as is a matter of common experience.

The Woburn field experiments, 1898, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 3. ser., 10 (1899), pt. 4, pp. 585-607).—Data in continuation of that previously noted (E. S. R., 10, p. 749) are tabulated for the yields of wheat and barley grown continuously for 22 years on the same plats, with and without manures, and of rotation experiments with barley, roots, red clover, and wheat; together with brief accounts of experiments with rye grass, alfalfa, *Lathyrus sylvestris*, pasture plats, green manuring, prevention of potato disease, and the curing of "finger-and-toe" in turnips.

Lime has proven especially valuable on the soils of the experimental fields where continuous application of fertilizers with ammonia salts has been practiced. Another effect of the lime has been to destroy spurry, a weed which was very prevalent on the unlimed plats and especially on plats fertilized with ammonia salts. The largest yield of wheat in 1898, 54.8 bu. per acre, was obtained on a plat fertilized yearly with 350 lbs. of superphosphate, and in alternate years with 200 lbs. of potash and 100 lbs. of ammonia salts (equal quantities of sulphate and muriate of ammonia). As to the influence of the manures

on the quality of wheat, nitrate of soda seemed to have the most injurious effects, much of the wheat being small and shriveled. Wheat from plats fertilized with ammonia salts was the best of all the series, being "exceedingly well grown and of good color."

The use of lime with nitrogenous fertilizers on barley had the effect of more than doubling the yield in some cases and greatly increasing it in others. It had the greatest effect when used with nitrate of soda and mineral fertilizers. The best looking crops and brightest grains were obtained where no nitrogenous manures were used. The poorest yields were obtained from plats fertilized with nitrate of soda alone.

In the rotation experiments the relative manurial value of decorticated cotton cake and maize meal was studied. With the barley crop, cotton cake gave better results than maize meal, the yield in the former case being at the rate of 33.4 bu. per acre as against 26.7 bu. in the latter. The artificial equivalent of cotton cake gave a yield of 30.4 bu. per acre as against 28.4 bu. with the artificial equivalent of maize used. The introduction of clover in the rotation had the effect of producing a very uniform stand of wheat on all the plats, and of entirely obliterating the effects of the decorticated cotton cake and maize meal. This latter fact has rendered necessary the exclusion of clover from the rotation.

Small-seeded, perennial, Italian, and annual rye grasses were sown separately in 1893 on different plats and fertilized yearly with 500 lbs. of damaged decorticated cotton-cake meal. The object of the experiment was to see how long each variety would keep its character. By 1898 the annual and perennial varieties had entirely disappeared. Considerable quantities of the Small-seeded and Italian varieties could still be found, but the plats had become so impure through the intrusion of other grasses that the experiment was discontinued.

Alfalfa was planted in 1889 on plats which had become "clover sick" through frequent seeding of clover. Annual applications of different combinations of superphosphate, sulphate of potash and ammonia, bone dust, and nitrate of soda have been made. Three or four cuttings have been obtained annually. For the first 7 years of the test the fertilizers showed no benefits, and sulphate of ammonia distinctly reduced the yield. For the years 1896-1898 a marked increase in yield occurred on plats receiving applications of sulphate of potash.

Lathyrus sylvestris, sown in 1890, has given good yields continuously, but the crop has been found useless as a feeding material, since stock do not care for it. Lime has proved a valuable fertilizer on permanent pasture lots. Tares have not been superior to mustard or rape when used as green manures. Potatoes were benefited by applications of Bordeaux mixture, even in seasons when little or no disease was present.

Field experiments, J. ATKINSON (*Iowa Sta. Bul. 45, pp. 216-229, figs. 4*).—This is a preliminary report on a system of experiments with field crops begun in 1898. Variety tests cover corn, spring wheat, oats, and barley. Shallow cultivation gave the largest yield of corn. Winter wheat is unprofitable on account of the severe winters. On mellow ground spring wheat gave a larger yield by disking corn stubble than by plowing 4 and 8 in. deep. Good results were obtained by sowing 1 lb. of rape seed per acre with oats for pasture after the oats are harvested. In order to avoid interference in harvesting the oats, it is advised to sow the rape 2 or 3 weeks later. Sowing a mixture of wheat and oats gave an increase in the total yield. Cutting back oats lessened the loss from lodging but lengthened the time of ripening. Soy beans and cowpeas, when grown at the station, did not form root nodules and the cowpeas did not ripen seed. Sorghum as a fodder plant is recommended for the State, and methods of seeding and curing and the feeding value are discussed. Brome grass (*Bromus inermis*) is considered valuable to the section, but further experiments are necessary before a definite report can be made.

In an experiment to test the shrinking of ear corn, a crib holding 7,000 lbs. of husked corn was built upon a pair of scales and weekly weighings made during 1 year. For 3 months, October to January, the loss in weight was 9 per cent; from January to April, $5\frac{1}{4}$ per cent; April to July, $3\frac{1}{4}$ per cent; July to October, $2\frac{5}{7}$ per cent. Total loss for the year, a fraction over 20 per cent.

Experiments in growing sugar beets covering 10 years indicate that the conditions in Iowa are favorable for the production of beets of superior quality for sugar making.

Results obtained in 1899 from trial plats of grain, fodder corn, field roots, and potatoes, W. SAUNDERS (*Canada Cent. Expt. Farm Bul. 34, pp. 52, figs. 2*).—Cooperative variety tests in continuation of those previously reported (*E. S. R.*, 10, p. 1034) are recorded. The plan of the experiments has remained as heretofore. The yields of each crop obtained at the different experimental farms are tabulated. The varieties giving the largest yields at the different stations were as follows:

Oats.—American Beauty, Banner, Miller, New Zealand, Holstein Prolific, Danish Island, Black Tartarian, California Prolific, Wide Awake, Salines, Early Maine, and Poland. Average yield per acre, 81 bu. 22 lbs. *Two-rowed barley*.—French Chevalier, Danish Chevalier, Sidney, Dunham, Beaver, and Canadian Thorpe. Average yield per acre, 49 bu. 41 lbs. *Six-rowed barley*.—Argyle, Claude, Mansfield, Manshury, Trooper, and Baxter. Average yield per acre, 52 bu. 16 lbs. *Spring wheat*.—Rumanian, Wellman Fife, Hungarian, Goose, Huron, Monarch, Preston, Rio Grande, Pringle Champlain, White Fife, Laurel, and Red Fife. Average yield per acre, 35 bu. 17 lbs. *Peas*.—Elder, German White, Picton, Carleton, White Wonder, Archer, Macoun, Chelsea, Victoria, Chancellor, King, and Nelson. Average yield per acre, 35 bu. 56 lbs. *Indian corn*.—Red Cob Ensilage, Champion White Pearl, Early Mastodon,

Angel of Midnight, Cloud Early Yellow, and Compton Early. Average yield per acre, 18 tons 485 lbs. *Turnips*.—Bangholm Selected, Perfection Swede, Halewood Bronze Top, Mammoth Clyde, Prize Purple Top, and Purple Top Swede. Average yield per acre, 32 tons 1,909 lbs. *Mangels*.—Yellow Intermediate, Ward Large Oval Shaped, Giant Yellow Intermediate, Giant Yellow Half Long, Gate Post (2nd sowing), and Lion Yellow Intermediate. Average yield per acre, 34 tons 767 lbs. *Carrots*.—Half Long White, Giant White Vosges, Improved Short White, Iverson Champion, Mammoth White Intermediate, and New White Intermediate. Average yield per acre, 24 tons 917 lbs. *Sugar beets*.—Danish Improved, Wanzlebener, Danish Red Top, and Vilmorin Improved. Average yield per acre, 24 tons 821 lbs. *Potatoes*.—American Wonder, Burnaby Seedling, Seedling No. 230, Holborn Abundance, Everett, Vanier, Empire State, Bovee, Seattle, Carman No. 1, American Giant, and Polaris. Average yield per acre, 386 bu. 40 lbs.

The average results obtained for the different crops for 4 and 5 years are also tabulated, and these data are considered to be the more valuable guide to the farmer in the selection of seed. The varieties which have given the highest averages during this period of years are as follows:

Oats.—Banner, American Beauty, Columbus, Golden Giant, Bavarian, Golden Beauty, Holstein Prolific, Early Golden Prolific, American Triumph, Abundance, White Schonen, and Wallis. Average yield per acre, 70 bu. 13 lbs. *Two-rowed barley*.—French Chevalier, Danish Chevalier, Beaver, Canadian Thorpe, Sidney, and Newton. Average yield per acre, 42 bu. 39 lbs. *Six-rowed barley*.—Manshury, Trooper, Odessa, Oderbruch, Common, and Royal. Average yield per acre, 47 bu. 4 lbs. *Spring wheat*.—Preston, Wellman Fife, Monarch, Goose, White Fife, Rio Grande, White Connell, Red Fife, Huron, White Russian, Pringle Champlain, and Red Fern. Average yield per acre, 31 bu. 7 lbs. *Peas*.—Crown, Carleton, Pride, New Potter, King (3 years), Paragon, Mummy, Archer (3 years), Trilby, Duke, Prince Albert, and Centennial. Average yield per acre, 34 bu. 2 lbs. *Indian corn*.—Red Cob Ensilage, Selected Leaming, Thoroughbred White Flint, Giant Prolific Ensilage, Angel of Midnight, and Champion White Pearl. Average yield per acre, 17 tons 1,392 lbs. *Turnips*.—Selected Purple Top, Perfection Swede, Bangholm Selected, East Lothian, Hartley Bronze, and Jumbo. Average yield per acre, 30 tons 1,104 lbs. *Mangels*.—Yellow Intermediate, Gate Post, Giant Yellow Intermediate, Mammoth Long Red, Giant Yellow Globe, and Prize Mammoth Long Red. Average yield per acre, 31 tons 427 lbs. *Carrots*.—Improved Short White, Half Long White, Giant White Vosges, Mammoth White Intermediate, Iverson Champion, and White Belgian. Average yield per acre, 19 tons 1,719 lbs. *Sugar beets*.—Danish Improved, Red Top Sugar, Wanzlebener, and Improved Imperial. Average yield per acre, 21 tons 611 lbs. *Potatoes*.—Seedling No. 230, Irish Daisy, American Giant, American Wonder, Late Puritan, Empire State, Carman No. 1, State of Maine, Clarke No. 1, Clay Rose, New Variety No. 1, and Dreer Standard. Average yield per acre, 347 bu. 21 lbs.

Woody beets (*Dent. Landw. Presse*, 26 (1899), No. 103, p. 1175).—This article summarizes the observations made by different sugar-beet growers on the frequent occurrence of abnormal seed-bearing specimens of beets grown the same season from spring planted seed. These seed-bearing beets usually have hard woody roots of low sugar content. Freezing the young plants seems to favor the growth of the seed-bearing specimens. Rimpau experimented with 2 beds of sugar beets planted in March. One was protected at night by a light covering and the

other left exposed to frosts. In the protected bed 3.8 per cent of the plants developed into seed-bearing specimens, and in the exposed bed 7.5 per cent. Experiments with two-year-old and one-year-old seed gave 14.8 per cent of seed-bearing beets with the two-year-old seed and 9.84 per cent with the one-year-old seed. Again, 100 large seed bolls which weighed 4.23 gm. produced 6.3 per cent of seed-bearing plants while 100 small seed bolls, having a total weight of 1.42 gm., produced 16.4 per cent of seed-bearing plants. Other experiments by Rimpau showed that the deeply planted seed produced more seed-bearing plants than seed planted normally in a similarly prepared seed bed. A period of drought, excessive rain, or any weather condition which checks the growth of the beets during any stage of growth, in the opinion of the same experimenter, tends to further the development of seed-bearing specimens.

Relative to the means of reducing the number of precocious seed-bearing plants to a minimum, it is suggested that seedsmen persistently discard strains of sugar beets which tend to produce these abnormalities, notwithstanding that the form, yield, and sugar content of the beets may be all that is desired. Growers should guard against planting too early in the season and thus subjecting the young plants to the effects of frost. Deep planting should be avoided and at the last hoeing all beets growing seed should be pulled out by the roots.

The comparative yield of corn from seed of the same variety grown in different latitudes (*Arkansas Sta. Bul. 59, pp. 109-122*).—Samples of seed corn were obtained from 18 different States in 1898 and 20 in 1899 and planted in comparative plats at the station. For the purposes of the experiment seed collected north of the thirty-eighth parallel was designated as “northern grown,” that collected between the thirty-eighth and thirty-fifth as “middle grown,” and that south of the thirty-fifth parallel as “southern grown.” Ten Northern, 7 Middle, and 3 Southern States were thus represented by the different varieties of seed. In all, 11 varieties were compared, many samples being procured of each variety. The yields obtained in the different latitudes with Leaming, Golden Beauty, Hickory King, Golden Dent, Champion White Pearl, Early Mastodon, and White Dent are tabulated and averaged. With these varieties the difference between yields of the same variety from different sources in the same latitude was sometimes greater than the average difference between varieties from different latitudes. The yields from seed of Golden Dent grown in the north latitude varied from 15.9 to 48.8 bu. per acre. Similar variations, though to a less extent, occurred with other varieties.

The average yields for two years from seed obtained from the different latitudes are shown for the varieties most uniformly represented in the different sections by the following table:

Average yields for two years of corn from different latitudes.

Name of variety.	From northern- grown seed.	From middle- grown seed.	From southern- grown seed.
	<i>Bushels.</i>	<i>Bushels.</i>	<i>Bushels.</i>
Leaming	20.98	26.20	17.20
Golden Beauty	32.81	45.775	50.475
Hickory King	24.855	31.81	29.10
Golden Dent	21.52	25.09	25.30
Champion White Pearl	22.62	32.00	30.10
Early Mastodon	33.54	33.75	33.45
White Dent	24.175	34.695	34.775
Average	25.785	32.76	31.485

"Thus it is seen that 75 samples of 7 varieties of corn from seed grown north of thirty-eighth parallel of latitude yielded an average of 25.78 bu. per acre; 49 samples of the same varieties from seed grown between the thirty-eighth and thirty-fifth parallel of latitude yielded an average of 32.76 bu. per acre, and 31 samples of the same varieties from seed grown south of the thirty-fifth parallel yielded an average of 31.48 bu. per acre. The middle section averaged 6.98 bu. per acre more than the northern and 1.28 bu. more than the southern section. . . .

"The results of the two years' experiments indicate that seed corn grown in the same or nearly the same latitude as that in which it is to be planted will give the best results, and that seed grown in the neighborhood where they are to be planted are preferable to those grown farther north or farther south."

Tables showing the weather conditions from March 1 to September 30, both years of the test, are appended.

Fertilizer, culture, and variety experiments on cotton, R. J. REDDING (*Georgia Sta. Bul.* 47, pp. 79-110).—Work in continuation of that previously reported (*E. S. R.*, 11, p. 138). The author states that the season for cotton was the most unfavorable in many years.

In 1899 25 varieties were tested. Arranged according to rank in value of yield and seed produced, Culpepper Improved stood first, followed by Texas Bur, Moss Improved, Schley, Russell Big Boll, Prize, Lee Improved No. 2, etc. Jackson Limbless stood twenty-third in the list. Moss Improved produced the largest percentage of lint, 38.3, and the smallest seeds, with the exception of one variety. Shire and King were the earliest varieties grown. The results of 6 years' tests show that early varieties are not, as a rule, the most productive.

The results obtained in the composite seed test, begun in 1898 (*E. S. R.*, 11, p. 138), lead to the conclusion that if the seeds of two equally productive varieties, one an early and the other a late cotton, be mixed, the resulting yield will be greater than that of either planted alone.

In the distance experiments it was found that with rows 4 ft. apart the yield of cotton was greater with 1 plant every 18 in. than with 2 plants every 36 in.; also that single plants every 12 in. in the row gave larger yields than at greater distance. In rows of varying width and with plants planted at different distances in the row the yields increased in proportion as the space between plants more nearly approached a square.

The plats used in the general fertilizer tests were located on typical old upland soil. The yields obtained with different fertilizers lead to the conclusion that a formula consisting of $3\frac{1}{3}$ parts phosphoric acid, 1 part potash, and 1 part nitrogen, all in an available form, is the most suitable for middle Georgia conditions.

Fractional applications of fertilizers have not been found profitable.

Some native forage plants for alkali soils, A. NELSON (*Wyoming Sta. Bul.* 42, pp. 23-45, figs. 12).—This bulletin discusses the forage areas of Wyoming, dividing them into 3 classes—mountain, hill, and plain. The two former areas, being well drained, are reasonably free from alkali. The latter area is divided into normal plains and alkali plains. The native plants found upon the alkali plains are described and discussed. These plants are found to have a greater or less value for forage, and it is the object of this bulletin to point out the more valuable ones, and to suggest measures for increasing their yield. The salt sages are found to be the most suitable for the Wyoming lands, and 4 perennials and 3 annuals are illustrated and described. Winter Fat, related to the salt sages, Indian Millet, Slender Wheat grass, and Alkali Meadow grass, are found on the alkali plains and are of value as forage. Tuber Bulrush is found in alkali marshes and is much relished by cattle. These plants are also described.

Effect of orchards in meadows, BURKI (*Landw. Jahrb. Schweiz.*, 13 (1899), pp. 135-151).—Investigations were made by the author to determine what effect on the yield and quality of grass would follow from the growing of orchard trees in meadows. Shade was the chief factor considered. The composition and yield of a large number of species of grass grown both in shade and in sunshine are tabulated. The data show that the first cutting of meadow hay was decreased on the average 32 per cent by the shade from the orchard trees, and the second cutting 59 per cent by the same cause. The decrease in yield was in general directly proportional to the nearness together of the orchard trees. Grass grown under fruit trees averaged 0.76 per cent less dry matter and 0.96 per cent less nitrogen-free extract than grass grown in the open sunlight. No marked influence of the shade on the protein content of the grass was observable except where comparatively large amounts of fertilizers were used, and then the protein content was greater in the grass grown in shade. The crude fiber and fat content was slightly higher in the grass grown in the sunshine, while the ash content was somewhat lower. Shade tended to promote the growth of orchard grass and a number of undesirable grasses, and to decrease the growth of French and English rye grass and red and white clover.

The produce of old and new varieties of oats, J. SPEIR (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1899), pp. 225-238).—In 1898, 3 new varieties of cross-bred oats were tested in comparison with the Potato oat, an old variety grown quite extensively throughout Scotland. The yields obtained from the different varieties were

as follows: Potato, 61½; cross-bred varieties—Waverly 99, Tartar King 92, Pioneer 86 bu. per acre. The same varieties of oats were grown in 1899 and several other varieties, including American Beauty, were also tested. The yield of the grain and straw and the analyses with reference to the food constituents of the straw of the different varieties tested are tabulated. In general the yields in 1899 were considerably less than for the preceding year. The yields of the new cross-bred varieties fell off in amount from 57 to 58 per cent and the Potato oat 36.5 per cent. In 1899, American Beauty, with a yield of 44 bu. per acre, was the best variety grown, followed by Yellow oat 43, Waverly 42, and Abundance 40 bu. per acre.

The Irish potato, R. H. PRICE and H. NESS (*Texas Sta. Bul.* 54, pp. 109-128, figs. 10).—A continuation of the fertilizer, variety, and storage tests with potatoes previously noted (E. S. R., 9, p. 830). In addition data are given of tests made to determine the relative merits of northern and southern grown potatoes for seed and the value of different-sized pieces for planting. Potato machinery is discussed and suggestions given regarding the growing of a second crop of potatoes during the season.

Of the 33 varieties of potatoes tested Triumph has proven the best early variety grown during a period of 4 years. Red Triumph has sold better in the market than White Triumph. By planting second-crop potatoes grown in Virginia better yields were secured than with potatoes grown in New York. Tubers averaging 2½ oz. each, planted whole, gave larger returns than 2 or 4 oz. tubers cut to ¼ or ½ oz. pieces.

In the fertilizer test the use of chip dirt, rotten sawdust, unfermented cotton-seed hulls, or muriate of potash has resulted in a loss in both wet and dry seasons. Both cotton-seed meal and sulphate of potash have been used with profit but the best results have been secured by the use of stall manure from cattle fed almost exclusively on cotton-seed meal and cotton-seed hulls. Scab was most abundant on the plats receiving the largest amount of nitrogenous fertilizers. It increased from 19 per cent in the case of cotton-seed meal applied broadcast to 30 per cent when the meal was applied in the furrow directly on the seed. In these experiments both cowpeas and sorghum have immediately preceded the potato crop. The different fertilizers used in these tests and the results obtained in the two seasons of 1898 and 1899 are recorded in detail. No definite conclusions are drawn and the work is considered in the nature of a report of progress.

No entirely satisfactory method has as yet been found for storing large crops of potatoes for any considerable length of time. The authors' conclusions from the results of 4 years' work along this line are as follows:

"Plant very early varieties and ship the crop just as early as it will do to harvest. If the season be dry and the markets crowded, let the crop stay in the ground about

4 weeks after maturing . . . and then harvest and market at once. . . . Some risk is run of losing the crop if a heavy soaking rain should come after the tubers mature. Grow a second crop whenever it can be grown. By spreading the tubers out on the floor of a cellar or even under the house where some light covering of straw or leaves can be placed over them, enough can be stored for family use until Christmas. Potatoes grown on well-drained sandy loam soils will keep better than those grown on stiff, heavy clay soils."

Notes on marketing potatoes and illustrated descriptions of a potato cutter, digger, sprayer, and smoothing harrow are given, together with suggestions regarding the management of first-crop potatoes for second-crop seed.

Experiments with potatoes, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 57, pp. 145-158*).—Investigations were undertaken to determine the "effect of spraying potato vines with Bordeaux mixture on the starch content of the tubers. As starch accumulates most rapidly when the plant is maturing, it seemed reasonable to presume that if spraying prevented blight and prolonged the life of the plant to its natural period of growth, the tubers would be of better quality with a larger proportion of starch than those from immature plants."

Arrangements were made with growers in Aroostook County, where large starch factories are located, for samples of potatoes from sprayed and unsprayed fields. Only merchantable tubers were used. The spraying was begun late, and none of the potatoes completely escaped the attack of blight. Sixteen samples, made up of 4 varieties, were analyzed and the data with reference to both mineral and food constituents were tabulated and compared with similar data obtained from other sources. The average starch content of 3 varieties of sprayed and unsprayed potatoes is shown in the following table:

Starch content of sprayed and unsprayed potatoes.

Variety.	Sprayed.		Not sprayed.	
	Number of samples.	Average starch content.	Number of samples.	Average starch content.
		<i>Per cent.</i>		<i>Per cent.</i>
White Elephant	5	19.32	3	17.52
Delaware	2	18.92	2	17.45
Carmen No. 1	1	18.03	1	17.07
Average		19.06		17.43

These results indicate an average increase in starch of 1.63 per cent, seemingly due to spraying with Bordeaux mixture. With the Hebron variety the larger starch content was found in the unsprayed potatoes. This variation was attributed to the soil differences of the fields in which the 2 samples were grown.

The starch content shown by chemical analysis is compared with the estimated starch content based upon specific gravity. The figures

“show in a striking manner the unreliability of the specific gravity method of determining starch in potatoes.”

A summary is given of considerable literature on fertilizing potatoes. On the basis of the chemical analysis of potatoes, the fertilizing constituents removed by a crop of 200 bu. per acre is calculated to be 37 lbs. of nitrogen, 16 lbs. of phosphoric acid, and 58 lbs. of potash. Twenty-six brands of so-called potato fertilizers were examined, and only 8 were found to resemble the above in proportion of constituents, and these contained much more phosphoric acid.

Fertilizer experiments with potatoes, B. SJOLLEMA (*Jour. Landw.*, 47 (1899), No. 2, pp. 105-140).—This is a report on a series of fertilizer experiments which have extended over a period of 17 years. In a comparison of barnyard manure and chemical fertilizers, the yield was about the same on each, but the starch content of the tubers was noticeably lower in the former case, being only 14.25 per cent as against 16.15 per cent in the latter. Barnyard manure was plainly unfavorable to the fullest development of starch. This conclusion, based on experiments in which the barnyard manure and chemical fertilizers were applied to different plats, was confirmed by other experiments in which each was applied to the same plat in different seasons.

In a comparison of sulphate of ammonia and nitrate of soda as sources of nitrogen for potatoes, the yield of tubers with the former was 7.3 per cent less than with the latter. At the same time their starch content was less by 0.5 per cent. As a result, the amount of starch produced was 11 per cent less on sulphate of ammonia than on nitrate of soda. This result may probably be explained, the author suggests, by the fact that nitrate of soda is a more readily available plant food.

In a study of the influence of different kinds of manures on starch content, a complete chemical fertilizer was compared with other fertilizers identical except that either nitrogen or phosphoric acid was omitted. The complete fertilizer applied in the usual quantities produced 31,500 kg. of tubers with a starch content of 16.15 per cent. The fertilizer containing no phosphoric acid produced 28,500 kg. of tubers with a starch content of 15.05 per cent; and the fertilizer containing no nitrogen produced 27,800 kg. with a starch content of 16.45 per cent. It appears that either phosphoric acid favors the formation of starch, or that nitrogen is unfavorable to it. It was shown by other experiments that both inferences are correct; but when the application of fertilizer was doubled in each case, the complete chemical fertilizer produced a starch content of 19 per cent, the fertilizer containing no phosphoric acid 18.4 per cent, and that containing no nitrogen 18.6 per cent—that is, nitrate of soda does not materially hinder the formation of starch provided all other elements of plant food are present in sufficient quantities.

Experiments are reported which appear to lead to the conclusion that a heavy application of potash neutralizes the detrimental effect of barnyard manure on the formation of starch.

In experiments on the effect of barnyard manure and chemical fertilizers, respectively, on succeeding crops of potatoes, the effect of an application of barnyard manure was almost as marked the second season as the first, but in the third season it was very much less, and in the fourth had practically disappeared. The effect of chemical fertilizers on succeeding crops was much less marked, but when the application of commercial fertilizers was double the amount usually applied the effect on the second crop was almost as great as in the case of barnyard manure. Other considerations in the course of the experiments, however, indicate that if the application of potash alone is doubled the same result would be reached.

The effect of different elements of plant food on yield and starch content of potatoes is shown in the following table:

The effect of different fertilizing constituents on yield and starch content of potatoes.

	Increase due to potash.		Increase due to nitrogen.		Increase due to phosphoric acid.	
	In yield per hectare.	In starch content.	In yield per hectare.	In starch content.	In yield per hectare.	In starch content.
	Kg.	Per cent.	Kg.	Per cent.	Kg.	Per cent.
Applied alone.....	15,250	1.4	550	a 0.3	260	0.7
With potash			4,150	a .5	3,330	.8
With nitrogen	18,850	1.2			2,680	.7
With phosphoric acid.....	18,320	1.5	2,970	a .3		
With phosphoric acid and nitrogen..	19,510	1.6				
With potash and phosphoric acid.....			4,160	a .2		
With potash and nitrogen					3,340	1.1

a Decrease.

Potash is seen to be the most important ingredient of a potato fertilizer. Nitrogen and phosphoric acid with potash gave only a small increase in yield over potash alone, and if potash is not included in the formula there is almost no increase. Nevertheless, nitrogen and phosphoric acid are necessary complements of potash, though in small amounts or less frequent applications, for a continued application of potash alone was found to result in a decreased yield.

Soy beans, a new drought-resisting crop, H. M. COTTRELL, D. H. OTIS, and J. G. HANEY (*Kansas Sta. Bul. 92, pp. 19-28, figs. 3*).—A description is given of the plant, with directions for planting, cultivating, and harvesting. The early yellow soy bean is recommended for planting in Kansas, and it is pointed out that some reported failures have been by reason of planting a late-maturing kind. Planting should be done after danger of frost is past, and cultivation should be shallow and level. The crop should be harvested when the pods turn brown and before the beans are wholly ripe. In harvesting, a knife attached to a cultivator and running just below the surface is recommended.

The threshing may be done with an ordinary grain separator by using blank concaves. The yield in Kansas is from 10 to 20 bu. per acre, and the cost of production varies from 40 to 55 cts. per bu.

The feeding value of soy beans is discussed, and 5 tests with pigs are briefly reported in which soy beans were compared with Kafir corn and corn meal. The experiments made show a saving by a mixed ration with corn or Kafir corn in fattening hogs of from 13 to 37 per cent per 100 lbs. of gain.

From the results of 10 years' experience at the station the author concludes that the soy bean is a profitable crop for the Kansas farmer. "It stands drought as well as Kafir corn or sorghum; it is not touched by chinch bugs; the grain is a richer feed than linseed meal, and the plant enriches the soil in which it is grown."

Alfalfa, G. L. CLOTHIER (*Kansas State Bd. Agr. Quart. Rpt. 1900, Mar. 31, pp. 7-39, figs. 11*).—The history, culture, and feeding value of the plant, compiled from the work of the agricultural experiment stations are given.

Distance experiment with corn, C. D. SMITH (*Michigan Sta. Rpt. 1899, p. 58*).—In a test of growing corn in drills and hills in rows different distances apart, the best results were obtained when the rows were fully $3\frac{1}{2}$ ft. apart, "either in hills equally distant or in continuous rows, the kernels being between 6 and 9 in. apart in the row."

Cotton, K. SUPP (*Tropenpflanzer, 4 (1900), No. 6, pp. 263-276*).—Statistics of growth and manufacture of cotton, with colored maps showing area of world's production.

Kafir corn, J. G. HANEY (*Kansas State Bd. Agr. Quart. Rpt. 1900, Mar. 31, pp. 52-65, figs. 2*).—History, cultural notes, and feeding value, compiled from various sources.

Culture of white lupines, P. P. DEHÉRAIN and E. DEMOUSSY (*Ann. Agron., 26 (1900), No. 2, pp. 57-77, figs. 4*).—White lupines were grown in pot and field experiments on calcareous soils well supplied with mineral elements. The results are given in detail and seem to demonstrate that without the presence of nodules on the roots of these plants growth is feeble and uncertain and premature death is frequent. At least 4 different sorts of bacteria form nodules on the roots of white lupines, but not all are equally efficient in furnishing nitrogen to the plant. It is owing to this difference in efficiency, rather than to the composition of the soil, that white lupines do not flourish in different districts equally well.

Tests of the value of seeds of first and second flowering, E. GAIN (*Sta. Agron. Nancy, Bul. 2, 1900, pp. 42-46*).—White lupine seed were selected from pods of the first and second flowering periods, respectively, and planted under similar conditions of soil and culture. From 33 to 50 per cent of the seeds from the second flowering failed to grow, and those that did live made a weak growth, the yield of pods and seed and total weight of the plants being scarce 50 per cent of that of the seeds obtained from the pods of the first flowering. Ordinarily the seeds of the different flowering periods are all harvested together. The undesirability of using such mixed seeds, as shown in this experiment, is commented upon.

Meadows of the lower course of the Saone, H. CORNET and E. DELORME (*Ann. Agron., 26 (1900), No. 3, pp. 140-155*).

When and how potatoes were introduced into Norway, O. OLAFSEN (*Tidsskr. Norske Landbr., 6 (1899), No. 11, pp. 504-506*).

Cultivation of the potato, A. C. TONNELIER (*El cultivo de la papa. Buenos Ayres: J. Peuser, 1899, pp. 22*).

The starch yield of different varieties of potatoes (*Deut. Landw. Presse*, 27 (1900), No. 36, p. 443).—The total starch content and the yield of first and second class product obtainable from each of 11 varieties of potatoes are reported.

Influence of the size of the potato vines on the yield, C. VON SEELHORST (*Jour. Landw.*, 48 (1900), No. 2, pp. 97-103; *Deut. Landw. Presse*, 27 (1900), No. 40, pp. 500, 501).—The author's experiments in the selection of potatoes for seed show that large vines tend to give large yields, and that this character is to a certain degree inherited.

Trials with potatoes, F. DESPREZ (*Semaine Agr.*, 20 (1900), Nos. 981, pp. 68, 69; 988, pp. 126, 127).—Blue Giant and Richter Emperor have proven the hardiest and most satisfactory varieties tested for 9 years. Notes on a number of other varieties grown are given, together with tabular matter as to yield, etc.

Report on experiments at the German potato culture station in 1899 (*Sächs. Landw. Ztschr.*, 48 (1900), No. 9, pp. 88-93).—Richter Emperor and Dabersche have given the most satisfactory results of a number of varieties tested for a period of years.

Monograph on rice, C. D. GIROLA (*Monografía del arroz*. Buenos Ayres: J. Peuser, 1899, pp. 63, figs. 5).

Rice, C. D. GIROLA (*Bol. Soc. Nac. Agr. [Lima]* 4. ser., 1900, No. 8, pp. 373-411, figs. 2).—A popular article on varieties, culture, enemies, etc.

Sugar beets in Sanpete and Sevier counties, L. FOSTER (*Utah Sta. Bul.* 63, pp. 22).—Results of cooperative experiments in these counties, with cultural suggestions and a discussion of factory conditions. The average sugar content of the beets grown in the 2 counties in 1899 was 15.72 per cent; purity, 82.01 per cent. Tables of analyses of beets grown in the years 1897 to 1899 in Sanpete, Sevier, Utah, and Weber counties are included in the bulletin.

Wholesale sugar-beet seed production in Germany, E. SCHAAF (*Bl. Zuckerrübenbau*, 7 (1900), Nos. 3, pp. 33-37; 4, pp. 49-57; 5, pp. 65-71; 6, pp. 81-88).

The wheat crop of California (*Sci. Amer.*, 83 (1900), No. 1, p. 9).—A description of the lands, culture, and storing, with especial reference to the machinery operated by steam power.

Macaroni wheats, G. VALDER (*Agr. Gaz. New South Wales*, 11 (1900), No. 3, pp. 210-212, figs. 5).—Several varieties of these wheats have been successfully grown at the Hawkesbury Agricultural College. The uses of these wheats for green fodder, hay, and for macaroni are noted.

HORTICULTURE.

Forcing tomatoes, A. T. JORDAN (*New Jersey Stat. Bul.* 141, pp. 18).—The author describes the methods generally observed in New Jersey in growing tomatoes under glass, and presents the detailed results of his investigations of problems connected with forcing tomatoes.

Thickness of setting (pp. 6-8).—Tomato plants were allowed 1½, 2, 2½, 3, and 3½ sq. ft. of bench surface per plant. Four crops were grown. In order to admit light and permit of a better circulation of air about the plants, it was found necessary to clip the leaves of plants given 1½, 2, and 2½ sq. ft. of space. Watering with liquid manure was practiced. The best results were obtained from the plants given the greatest number of applications. The maximum yield per plant was from the plants having 2½ sq. ft. of surface, but the maximum yield per square foot of

bench space (28.5 oz.) was obtained when the plants occupied 2 sq. ft. of bench. Plants given $1\frac{1}{2}$ sq. ft. of bench stood second in yield, but when thus closely crowded together too severe pruning was required to give satisfactory results.

Fertilizers with surface v. subwatering (pp. 8-10).—The soil used was a clay loam, to which 3 per cent of peat moss was added. In two instances regular forcing soil was used for comparison, and in two others sifted coal ashes, to which 3 per cent of peat moss was added. Like amounts of mineral fertilizers (a mixture of 200 lbs. muriate of potash and 350 lbs. acid phosphate per acre) were used on each plat. Liquid manure was applied to the plats in some instances. Plats were duplicated, one series being surface-watered and the other subwatered. The yields obtained on the different soils by the different methods of manuring and watering are shown in tabular form. The results obtained are summarized by the author as follows:

"In 5 of 7 plats subwatering has increased the yield—in one case nearly 50 per cent (49.22), and averaging for the 5, 31.13 per cent.

"Relatively, the increase caused by subwatering has been greater upon the nitrate plat, the percentages of increase being for the nitrate 49.22, as against 46 for the sulphate, 39.15 for blood, 36.79 on the forcing soil, and 4.7 on the ashes. Upon the soils used yard manure as a source of nitrogen is superior to the commercial forms applied, *i. e.*, nitrate of soda, sulphate of ammonia, and dried blood. The increase over nitrate of soda under identical conditions was 5.11 oz. per square foot.

"As a result of 4 crops without renewal of soil, sifted coal ashes with 3 per cent peat, fed with a complete chemical fertilizer, has given, where surface watered, a yield exceeding any other by 3.89 oz. per square foot, and under subwatering is second only to the regular forcing soil."

The effect of varying amounts of nitrogen on different soils (pp. 10-13).—Tomato plants were grown in boxes 18 in. square and 12 in. deep, filled with either nearly pure sand, sandy soil, or clay soil. Three boxes of each soil received mineral fertilizers (potash and phosphoric acid) only, 3 mineral fertilizers plus 160 lbs. of nitrate of soda, and 3 mineral fertilizers plus 320 lbs. of nitrate of soda.

Lorillard and Chemin varieties of tomatoes were grown. With nearly pure sand the yield obtained with the smaller application of nitrate was nearly 5 times as great as that obtained where minerals only were employed. On the sandy soil the yield was nearly double, and on the clay soil a little more than double as great. The increase in yield per box due to the larger application of the nitrate on the different soils was as follows: Nearly pure sand, 43.18 per cent; sandy soil, 58 per cent, and clay soil, 19.7 per cent. These results are considered as varying in every respect from the results previously obtained under field conditions.

Boxes and pots v. benches for forcing tomatoes (pp. 13, 14).—The boxes used were similar to those described above. The pots were ordinary 10-inch pots, holding approximately 0.3 cu. ft. of soil. Plants

on the benches had approximately $1\frac{1}{2}$ sq. ft. of bench space. The soil, varieties, methods of training, handling, pruning, manuring, etc., were the same in each case.

"The lot grown on benches has given the largest total yield and yield for space occupied, but has given the lowest average weight per fruit. Those grown in pots have given almost as large a yield for the space occupied and the largest average weight per fruit. This large yield is probably due, in part at least, to the fact that the pots were set in the extreme south end of the bench, and thus had the full advantage of the light. Placing each lot upon the same basis as to amount of soil, these results might be changed. However, the smaller quantities of soil dry out quickly, and consequently require very close attention. We much prefer the use of benches."

Single-stem v. three-stem training (pp. 14, 15).—Nine plants were grown under similar conditions. Six were trained to single stems and 3 to 3 stems. The average weight of fruits grown on the single stems was 3.98 oz., and the yield per square foot of bench space 48.77 oz. With plants trained to 3 stems the average weight of the fruits was 4.07 oz., and the yield per square foot of bench space 38.77 oz. The claim that 1 plant trained to 3 stems will occupy no more room than 2 plants trained to single stems was not borne out in these experiments. The results lead the author to recommend the single-stem method of training for forcing tomatoes.

Financial considerations involved in forcing tomatoes are considered. Based on the yields per square foot of bench in these experiments (24.23 oz. salable fruit) and the prices obtained for tomatoes during the 2 seasons 1898 and 1899 (67.5 cts. per square foot of bench for 2 crops), the author calculates the value of the crops from a house 20 by 100 ft. to be \$972 a year, which, after deducting the cost of coal and labor, leaves a profit of \$693.50.

In these experiments tomato blight (*Cladosporium fulvum*) was held in check by a mixture of 6 lbs. of copper sulphate, 4 lbs. of lime, and 90 gal. of water. Tobacco smoke was successfully used in controlling the white fly (*Aleyrodes vaporariorum*).

Pear growing in New Jersey, A. T. JORDAN (*New Jersey Stas. Bul.* 142, pp. 14).—The discussion of this subject is based largely on data obtained from the fruit survey of the State made in 1895 (E. S. R., 8, p. 887). The subjects concerned are soils, varieties, purchasing stock, planting, cultivating, manuring, pruning, thinning, life of pear orchards, insects and diseases, picking and marketing, yields, expenses, and profits.

At the present time pears in New Jersey rank third in commercial importance among orchard fruits. Keiffer and Bartlett are the leading varieties. The average yield of orchards in 1898 was 68.2, and in 1899, 99.4 bbls. per acre. Some 5,650 acres in the State are devoted to pear culture. The net receipts vary from \$25 to \$950 per acre, and average \$256.45 per acre.

"Plowing early in May and keeping the soil well stirred through the season, ending with the sowing of crimson clover in August for the winter cover crop, is the practice of the best growers. Two good mixtures of fertilizers to apply are (1) equal parts of ground bone, muriate of potash, and acid phosphate; and (2) $1\frac{1}{2}$ parts of ground bone and 1 part of muriate of potash; 500 lbs. per acre is usually applied. Where nitrogen is needed, nitrate of soda is one of the best forms, but may be omitted when crimson clover is grown.

"[Pruning before the buds start and later thinning of the fruit is recommended.] Fire blight and leaf blight are the two worst diseases. In the early stages of the first, cut well below the injury and burn. If well started or into the body of the tree, destroy it completely. Spraying will control the second.

"With good trees and proper varieties to begin with and careful attention to details, as outlined, good returns may be confidently expected from the culture of the pear."

Observations and suggestions on the root killing of fruit trees, J. CRAIG (*Iowa Sta. Bul.* 44, pp. 179-213, figs. 9).—This bulletin gives a review of the root killing of fruit trees in the State and the work of the station thereon, supplemented with notes from nurserymen and others. The work covers especially the freeze of February, 1899, when the losses were very heavy. Young apple trees under 5 years suffered more than older stock. The effect was worse on sandy soils not covered with vegetation. The losses with plums emphasized the value of American stocks. The only grapes exempt from injury were the pure or half blood natives.

To overcome injury to nursery stock severe heading back with apples gave the best results, and with plums cutting trees back to straight sticks 2 or 3 ft. in height. It was noticed that there was an effort on the part of trees to recover by throwing out roots from the scion, especially where the stock had been killed. It was found that banking young apple trees with earth aided this effort. In the case of nursery stock, however, it is advised in 9 cases out of 10 to dig up and burn injured trees. Nurserymen are advised to use hardy stock in grafting.

There is appended a table of information from 62 leading fruit growers of the State on the subject of root killing by cold. From a canvass of the whole field, the writer concludes that the lack of a protecting blanket of snow coincident with unusually severe cold was the chief cause of the great losses by root killing, and that the amount of loss bore a direct relation to the severity of the frost. Trees suffered most on clean soils and on exposed dry knolls with northern aspects. To obviate root killing the writer recommends cover crops, preferably mammoth red clover or hairy vetch; the use of congenial and hardy stocks for grafts; and, on soil well drained, deep planting.

Coffee grafting—some results heretofore obtained and its future importance, J. G. KRAMERS (*Teysmannia*, 10 (1899), No. 11, pp. 535-568).—The author gives an outline of the history of efforts made to graft Java coffee on hardy Liberia stocks for the purpose of resisting the attacks of nematodes, points out some reasons for success or

failure, and describes the 2 methods that have so far been most successful. The coffee tree is difficult to graft. It wilts easily, and if all the conditions are not favorable a good union is not formed. Although some of the scions usually live, the percentage by the old method has been too small to make such grafting an economic success.

The system of grafting by approach of 2 seedlings in the cotyledonary method has given good results. By this method one cotyledon with a portion of the epidermis of the hypocotyl is cut away from the Liberia seedling and a portion of the epidermis between the 2 cotyledons is removed from the Java seedling. The two are then brought together at the cut surfaces, carefully tied up, and replanted. After a few weeks the remaining cotyledon and the plumule are cut away from the Liberia seedling, and later the hypocotyl of the Java seedling is severed.

The other method recommended is similar to that often used in grafting conifers. The scion of the Java or other desirable variety is inserted into the terminal bud on a branch of the Liberia. The wound is carefully covered and the young shoot protected so as to prevent transpiration as far as possible during the time that the union between scion and stock is taking place.

In the course of his work the author had occasion to examine the roots of a number of grafted Liberias of different ages, and in almost all cases found them free from nematodes. The few cases in which nematodes were found were on diseased trees, and it seemed probable that the parasite had effected a lodging on account of the diseased condition rather than that it had caused the disease.—H. M. PIETERS.

Strawberry notes for 1899, A. L. QUAINANCE (*Georgia Sta. Bul.* 48, pp. 147-173, pls. 6, figs. 5).—Details of tests of varieties, methods of treatment in the row, and trials of fertilizers form the basis of these notes. Similar work at the station has been previously reported (*E. S. R.*, 8, p. 785).

Tables showing the yield at different dates of picking are given for 60 varieties tested in 1899. Beder Wood stood first in total yield of early fruit; Lady Thompson second in the amount of early fruit. Lady Thompson is considered a good variety for either local or distant markets. Seventeen of the varieties not previously tested at the station are described.

In a comparative test of growing strawberries in hills and in matted rows 12, 18, and 24 in. wide and 4 ft. apart, it was found that the yields increased with the width of the matted rows. The yield obtained on the plats planted in hills was scarcely more than one-third of that obtained in matted-row culture. The 18 in. matted rows gave a yield of 134.5 qts. per acre over the 12 in. rows, and the 24 in. matted rows 282 qts. per acre over the 18 in. rows. The author believes, however, that the 18 in. matted rows will give the maximum yield

consistent with cheapness of cultivation since the space left between the 24 in. rows is too narrow for cultivation with the ordinary implements.

The effects of doubling and in some instances quadrupling the essential fertilizer elements in a normal formula, analyzing 8 per cent of phosphoric acid, 8 per cent of potash, and 4 per cent of nitrogen, and in substituting cotton-seed meal for nitrate of soda, and kainit for muriate of potash in the normal formula were studied. The results are given in tabular form. Substitution of kainit for muriate of potash resulted in an increased yield of 594 qts. per acre. Doubling or quadrupling the amount of kainit used in the normal formula decreased the yields. Doubling the amount of nitrate of soda in the normal formula was not financially profitable. When the normal formula was supplemented in the spring by a dressing of nitrate of soda, the yield was increased by about 200 qts. per acre. The substitution of cotton-seed meal for nitrate of soda resulted in considerably decreased yields.

Cultural directions reprinted from Bulletin 32 of the Station (E. S. R., 8, p. 785) are appended.

The absorption of water by orchids, R. G. LEAVITT and R. M. GRAY (*Amer. Gard.*, 21 (1900), Nos. 271, pp. 148, 149; 272, pp. 168, 169; 273, p. 186; 274, pp. 206, 207, fig. 1).—The authors made investigations to determine which of the vegetative parts of orchids—leaves, bulbs, stems, bulb scales and roots—are capable of absorbing water, and whether in liquid or gaseous form.

Leaves of 20 species of orchids were plunged under both warm and cold water and also sprayed in imitation of rain. The experiments were performed in light and in darkness and the submergence lasted from 2 to 6 days. Change in weight was determined by weighing on delicate scales. With thick-leaved species, absolutely no absorption of water took place, however long the submergence. With 6 of the more herbaceous sorts, a slight increase took place after 2 days' submergence, but this was thought to be due to imperfections, such as fungus spots, since when these perforations were sealed with vaseline no further increase in weight took place. Pseudo-bulbs and bulb scales surrounded by wet wrappings of filter paper or cotton or plunged under water failed to absorb appreciable amounts of water. In a similar manner when leaves, pseudo-bulbs, and bulbous stems were exposed in a closed receptacle having an atmosphere nearly saturated with water vapor, no increase whatever but instead a decrease in weight followed in every instance. From these results the authors conclude that "leaves and stems do not function as organs for the absorption of water in any form."

Theories of well-known botanists regarding the absorption of water by orchids are noted in some detail.

In one experiment with orchid roots the roots were kept in a box where the atmosphere had a nearly constant water-vapor-saturation content of 95 per cent. "The cut ends of the roots were generally sealed. The roots were sometimes partially dried out before exposure in the box, and sometimes taken from unwatered plants and put into the box directly. The trials lasted from 2 to 4 days, but in several cases much longer." Roots from 24 species were used in the test. The roots continually decreased in weight and finally shriveled and died, thus showing that water vapor was not taken up, though present in more copious amounts than usually occur in nature. "Other roots taken from the same plants at the same time and kept in the same box but supplied with liquid water remained green, plump, and vigorous, long after the first were quite dead. This shows that death came from lack of water, not from being severed from the plant."

Plants hung in the greenhouse, where the humidity rarely if ever went below 80 per cent, and not watered for 2 months, produced new shoots and new roots but steadily decreased in weight. In another test, where the water evaporated by the leaves and stem of an orchid was absorbed by calcium chlorid while the roots were kept in a damp box having a humidity saturation of 95 per cent, the orchids constantly lost in weight through the roots, and the plants drooped for want of water.

The results obtained in these experiments are believed to show that if water absorption by aerial roots takes place at all the function is of minor importance.

Report of Beeville Station on cabbage and cauliflower, B. C. PITTS and S. A. McHENRY (*Texas Sta. Bul.* 52, pp. 42-52).—Notes on the germination, growth, yield, character, and quality of 35 varieties of cabbage and 8 varieties of cauliflower. From the results of repeated tests the following varieties of cabbage are recommended, in the decreasing order of their importance:

Early varieties.—Early Jersey Wakefield, Early Winningstadt, Maule Winningstadt. *Medium early varieties*.—Improved Early Summer, Chase Early, Stein Early Flat Dutch, Fottler Short Stem, Danish Ball Head. *Late varieties*.—Lauderback All Year, Autumn King, Burpee Sure Head, Frotcher Superior Large Late Flat Dutch, St. Denis (small), French Market (medium size), Crescent City Large Flat Dutch.

The following early varieties of cauliflower, suited to the southwest section of Texas, are recommended: Le Normand Short Stem, and Henderson Early Snowball; for late planting, Late Italian Giant.

Bermuda onions (*Amer. Gard.*, 21 (1900), No. 282, p. 343, fig. 1).—Descriptive of the growing and marketing of Bermuda onions. The land is enriched with well rotted cow or pig manure. The seed is sown in September and the crop harvested from January to May. A rigid system of inspection covers all shipments to the United States.

Nitrate of soda in vegetable culture, ROMBAUT and SIMON (*Belg. Hort. e' Agr.*, 12 (1900), Nos. 2, pp. 21, 22; 3, pp. 38, 39).—Effect of nitrate of soda on the production of potatoes, rhubarb, and tomatoes.

Market gardening, H. R. KINNEY (*Massachusetts State Bd. Agr. Rpt.* 1899, pp. 86-112).—Suggestive and practical paper on market gardening, dealing with hotbeds, vegetable-storage cellar, soils, manures, and the culture of different vegetables.

The home fruit garden, F. A. WAUGH (*Vermont Sta. Bul.* 74, pp. 89-97).—Popular directions for the location, preparation of the soil, planting, and tending of the various orchard and small fruits which go to make up a home fruit garden.

Second report on Arkansas seedling apples, J. T. STINSON (*Arkansas Sta. Bul.* 60, pp. 123-134, figs. 4).—The writer gives the results of further study of Arkansas seedlings, a continuation of work previously reported (*E. S. R.*, 10, p. 48). Twenty-five varieties are described and characteristics noted. An effort is made to straighten the nomenclature of the apples noted and their value as new economic varieties is discussed.

The curing of apricots, J. B. NEFF (*California Fruit Grower*, 25 (1900), No. 629, p. 4).—A paper read before the Pomological Society of Southern California.

Check list of hybrid plums, F. A. WAUGH (*Vermont Sta. Bul.* 75, pp. 101-110).—This check list has been prepared particularly for the use of nurserymen and cataloguers. It contains as far as possible the following data respecting each of the 65 varieties noted: Name, original publication of the same, Vermont publications concerning it, certain facts relative to its origin and introduction, and its parentage.

Fruit list for Virginia, W. B. ALWOOD (*Virginia Sta. Bul.* 98, pp. 41-49).—This is a compiled list based on the personal observations of the author, and supplemented by a consensus of the best experience gathered from State growers. It includes such old standard varieties and promising newer sorts as it is thought will be of value for planting orchards throughout the State. The list includes 17 varieties of apples, 11 pears, 4 quinces, 21 peaches, 12 plums, 10 cherries, 3 blackberries, 6 raspberries, 5 currants, 3 gooseberries, 11 strawberries, and 12 varieties of grapes.

Strawberries, C. C. NEWMAN (*South Carolina Sta. Bul.* 49, pp. 27, pls. 7).—This is a popular bulletin on growing strawberries. The questions discussed are sexuality, selection, planting, cultivation, and mulching. Ninety-five varieties were tested at the station during the season. A list is given of varieties suited to the locality and a list of the varieties not promising for the section. Photographic reproductions are given of the berries of 36 varieties. The following 6 have proven the best all-round berries tested: Haverland, Brandywine, West Lawn, Lady Thompson, Bismarck, and Bubach.

Resistant vines and vineyards in California, G. HUSSMANN (*California Fruit Grower*, 25 (1900), No. 633, p. 5).—A consideration of varieties least affected by phylloxera and of vineyard and bench grafting. Vineyard grafting is considered cheaper and more satisfactory than bench grafting.

The wholesale grape nursery; complete directions for the work connected therewith, R. SPÖRR (*Die Rebenschule im Grossbetriebe, eine ausführliche Beschreibung sämtlicher in der Rebenschule vorkommenden Arbeiten. Vienna and Leipsic: A. Hartleben*, 1900, pp. 139, figs. 55).—The author describes in a thorough manner all the details involved in the growing of grape nursery stock on a wholesale scale. Discussions as to the theory of grafting, methods of grafting and the growing of vines by grafts, roots, and American cuttings occupy the larger part of the work. Chapters on grape houses, grafting and packing rooms, and on grape nursery bookkeeping conclude the book.

American vines; their adaptation, culture, grafting, and propagation, P. VIALA and L. RAVAZ (*Melbourne: F. W. Niven & Co.*, 1899, pp. 88).—This is a translated abridgment of the second French edition by W. P. Wilkinson and Joseph Gassies.

The influence of precipitation and fertilizers on the yield of grapes, B. CHAUZIT (*Message Agr. Midi*, 1900, I, No. 2, pp. 50, 51).

Future of our wine industry and the results of manuring vineyards in Europe and Australia, F. E. H. W. KRICHAUFF (*Adelaide*, 1899, pp. 36).

Reconstruction of vineyards, L. RAVAZ (*Reconstitution du vignoble. Paris: G. Masson*, pp. 148, figs. 31).—Chapters are given on conditions which influence the growth of vines, as climate and soil; the species and varieties of American vines.

descriptions of all the more important being given; methods of vine reproduction as by buds, cuttings, grafts, etc., with notes on grape-nursery management; and on the establishment of a vineyard.

Culture of vanilla (*Bol. Soc. Agr. Mexicana*, 24 (1900), No. 21, pp. 415-417).—A description of the plant, its culture, and preparation for market.

Vanilla (*Bul. Bot. Dept. Jamaica, n. ser.*, 7 (1900), No. 3-5, pp. 45-51).—Cultural instructions with outlines of the methods of curing the fruit followed in Guiana, Peru, Mexico, and Réunion.

The cultivation and uses of rosella, D. JONES (*Queensland Agr. Jour.*, 6 (1900), No. 5, pp. 371-375, figs. 2).—Popular directions for the culture and utilization of this fruit (*Hibiscus sabdariffa*).

Gutta-percha, E. OBACH (*Die Guttapercha. Dresden: Steinkopff & Springer, 1899, pp. 114, figs. 61*).—The author discusses the history, botany, culture, geographical distribution, and composition of gutta-percha; describes the processes employed in the purification of the raw material; and gives the chemical composition, physical and mechanical properties, uses, consumption in England, substitutes, relation to oxygen and ozone, and methods of preservation of purified gutta-percha.

Florists' manual, W. SCOTT (*Chicago: Florists' Pub. Co., 1899, pp. 235, figs. 225*).—This is a reference book for commercial florists. It treats alphabetically of the character, culture, and handling of all greenhouse plants of commercial importance and of all subjects, such as greenhouse building, packing plants, decorations, fungicides and insecticides, soils, potting, etc., pertaining thereto. The book is well illustrated, and is intended as a reference book and guide for all florists not specialists.

Comparative study of 34 varieties of Italian cannas, E. ANDRÉ (*Rev. Hort.*, 72 (1900), No. 10, pp. 258-261, figs. 2).

Origin and amelioration of the garden gladioli (*Florists' Exchange*, 12 (1900), No. 25, pp. 628, 629).—History of the plant and of its improvement.

Culture of water lilies and aquatics, P. HENDERSON (*New York: P. Henderson & Co., [n. d.], pp. 41, figs. 21*).—This is a reprint from the author's "Gardening for Pleasure."

Nomenclature of all the known roses with indications as to their race, originator, year of production, color, and synonyms, L. SIMON and P. COCHET (*Nomenclature de tous les noms de roses connus, avec indications de leurs race, obteneur, année de production, couleur, et synonymes. Metz: A. Béha, 1899, pp. 187*).

American greenhouse construction and cut-flower production (*Möller's Deut. Gart. Ztg.*, 13 (1900), Nos. 3, pp. 28-32, figs. 8; 5, pp. 50, 51, figs. 8; 6, p. 62, figs. 4; 7, pp. 88-90, figs. 4; 10, pp. 108-110, figs. 7).

Ornamental shrubs, L. D. DAVIS (*New York: G. P. Putnam's Sons, 1899, pp. 338, figs. 107*).—This book discusses "ornamental shrubs for garden, lawn, and park planting, with an account of the origin, capabilities, and adaptations of the numerous species and varieties, native and foreign, and especially of the new and rarer sorts suited to cultivation in the United States." It is not designed as a scientific treatise, but is written more especially for those interested in plants and flowers who may have no knowledge of botany.

FORESTRY.

Tree planting in Utah, U. P. HEDRICK (*Utah Sta. Bul.* 62, pp. 215-260, pls. 2, figs. 12).—In this bulletin an account is given of the behavior of 40 species of timber and shade trees now growing on the grounds of the station. The experiment was begun in the spring of 1890, with the object of testing the adaptability of various species of trees to that region, and of demonstrating the best method of planting

and caring for them. In addition to this experiment the station is conducting, in cooperation with the Division of Forestry of this Department, experiments in tree planting to ascertain the adaptability of the principal economic species to the plains.

The annual precipitation and temperatures are given for the State, and a general statement made concerning the method of planting and the condition of trees of each of the forest species. The planting, cultivation, and irrigation was about the same as would be given an orchard, except that the cultivation ceased with the sixth summer.

The species tested are described at length, and their relative adaptability and behavior are described. Among the more promising trees for that region (as shown by the results of 9 years' experiments), with their height and circumference, are the following:

Average growth of forest trees for nine years.

	Height.	Circumference.
	<i>Fect.</i>	<i>Inches.</i>
<i>Populus deltoides</i>	39	40
<i>Populus alba bolleana</i>	43	29
<i>Populus nigra italica</i>	46	40
<i>Populus alba nigra</i>	30	40
<i>Populus tremuloides</i>	36	23.5
<i>Populus balsamifera intermedia</i>	37	29
<i>Populus laurifolia</i>	40	41.5
<i>Salix laurifolia</i>	25	18
<i>Salix fragilis</i>	20	18
<i>Juglans nigra</i>	20	15
<i>Juglans cinerea</i>	18	13.5
<i>Ailanthus glandulosa</i>	16	14.5
<i>Catalpa speciosa</i>	18	22
<i>Betula papyrifera</i>	18	13.25
<i>Alnus glutinosa</i>	22	21.5
<i>Ulmus americana</i>	24	21.75
<i>Platanus occidentalis</i>	17	13
<i>Acer saccharum</i>	23	15
<i>Acer saccharinum</i>	21	13
<i>Acer negundo</i>	35	40
<i>Robinia pseudacacia</i>	23	22
<i>Gleditsia triacanthos</i>	21.5	19
<i>Tilia europæa</i>	19	15
<i>Morus alba tartarica</i>	22	18
<i>Pinus strobus</i>	14	12

<i>Picea canadensis</i>	8	10.5

Fertilizers in the culture of osier willows, P. WAGNER (*L'Engrais*, 15 (1900), No. 11, pp. 254, 255).—A series of experiments with various fertilizers is reported, showing that the growth of osiers can be greatly promoted by means of liberal manuring. The product was trebled by the application of 1,650 lbs. of phosphatic slag and 550 lbs. of nitrate of soda per acre. With the same amounts of slag and nitrate of soda combined with 660 lbs. of a 40 per cent potash salt the yield was quadrupled.

The trees of Vermont, ANNA M. CLARK ET AL. (*Vermont Sta. Bul.* 73, pp. 33-86, figs. 58).—This bulletin is introduced by the following statements:

"The following account aims to include the native and spontaneous trees of the State, together with brief mention of such others as are commonly cultivated. It

is primarily addressed to readers who have little or no botanical training, but who may wish to learn the names of the trees and the characters by which they may be recognized, as well as the main facts as to their occurrence and distribution in the State. . . . It is especially to the children of Vermont, and to the teachers of these children, either at home or in school, that it is hoped this publication will prove most interesting and most useful."

The bulletin contains descriptions of 97 species, representing 18 families. Each species is illustrated by original drawings.

Drawings of the forest trees of Japan, H. SHIRASAWA (*Iconographie des essences forestieres du Japon*. Tokyo: Minister of Agriculture and Commerce, 1900, pls. 88).—This is a collection of carefully drawn colored plates of about 150 arborescent species of Japan, showing the flowering and fruiting branches, dissections of flowers and seeds, bark, transverse, radial, and tangential sections and magnified specimens of the wood.

The identification of timber, D. F. MACKENZIE (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 183-224, figs. 83).—Illustrated descriptive notes are given upon the timber of 63 species of trees. Photomicrographs of transverse and tangential sections of most of the species are given, and the principal structural and physical characters of each kind of timber are described.

DISEASES OF PLANTS.

A fruit-disease survey of the Hudson Valley in 1899, F. C. STEWART and F. G. BLODGETT (*New York State Sta. Bul.* 167, pp. 275-308, pls. 4).—A report is given on the distribution and amount of damage done by fungus diseases in the Hudson Valley during 1899. The season was an unfavorable one for the development of parasites, and on this account diseases usually very common and destructive did little or no damage. The data presented in this bulletin were secured by circulars of inquiry and personal observations by the authors.

The diseases mentioned are: Apple diseases—scab, leaf spot, twig blight, canker, sooty blotch, russetting of fruit, rust, and sun crack. While all these diseases were observed, the apple crop was in no way injured by any of them. Blackberry diseases—orange rust and leaf spot, the orange rust having been rather destructive. Cherry diseases—fruit spot, leaf spot, black knot, witches' brooms, powdery mildew, and winter injury. Currant diseases—leaf spot and cane blight, both of which were somewhat destructive. The statement is made that the currant-cane blight occurring in the Hudson Valley is not caused by *Nectria cinnabarina* but by a sterile fungus. The exact proof of this fact by inoculation experiments is lacking, but the occurrence in a large number of cases of sterile fungus with the disease is considered sufficient proof. Gooseberry diseases—powdery mildew, root rot, and a dwarfed condition of the foliage which is not ascribed to any particular cause. The root rot has been known for a number of years in one locality and is gradually spreading. It is said to be due to *Dematophora*. Grape diseases—black rot, downy mildew, root rot, chlorosis, and black knot. The latter disease, while somewhat resembling the black knot of plum and cherry due to

Plowrightia morbosa, was of an entirely different origin. It has been considered in Europe to be due to the action of frost, and has received little attention in this country. Peach diseases—winter injury, leaf curl, yellows, fruit rot, leaf-tip burn, powdery mildew, and scab. Pear diseases—scab, leaf blight, fire blight, body blight or rough bark, and winter injury. The body blight or rough bark is generally considered to be a form of fire blight due to *Bacillus amylovorus*, but according to recent investigations of the station it is now thought to be caused by the apple canker (*Sphaeropsis malorum*), an account of which is given in Bulletin 163 of this station (E. S. R., 12, p. 61). Plum diseases—black knot, fruit rot, leaf blight, and leaf curl. Quince diseases—fruit spot, leaf blight, and fire blight. Raspberry diseases—anthracnose, rust, root galls, winter injury, cane blight, and leaf spot. The cane blight is apparently due to some species of *Phoma*, but as yet no inoculations have been made. Notes on the leaf blight and sun scald of strawberries complete the bulletin.

A sugar-cane pest in Madras, C. A. BENSON (*Indian Agr.*, 25 (1900), No. 1, pp. 14-17).—Notes are given on an investigation begun toward the end of 1897 to determine the cause of a disease of sugar cane. The disease was found not to be of recent origin, and was distributed rather generally throughout the region in which sugar cane was produced. The disease exhibited all the symptoms characteristic of an attack by *Trichosphaeria sacchari*, different stages in its life history being known as root fungus, rind fungus, etc. Canes but slightly affected show no external signs of disease, but transverse sections show one or more bright red spots in some of the internodes, and if these are followed by longitudinal sections they appear as red streaks which branch at the nodes. Where the disease is more advanced, the coloration extends to the ground tissue, so that any section may show red patches. When the disease is still further advanced, the nodes and later other portions become black, the leaves wither, and the entire cane dries up.

The methods adopted in India for growing sugar cane seem to be such as to foster the spread and continued presence of this disease. Some attention was paid to the extent in which different varieties were affected, and it is stated that a comparatively slender cane known as Yerra seems to suffer less than others. It probably owes its partial immunity to the thick rind and to the fact that it does not crack to any great extent.

The author believes that although the disease at present is epidemic in Madras, there is no occasion for alarm, as it has been known there for at least 30 years, sometimes severe and at other times almost disappearing. Attention to cultivation, destruction of litter, and abandoning the growth of cane for a few years, together with giving up the practice of ratooning altogether would probably check the disease.

Gummosis of *Prunus japonica*, G. MASSEE (*Kew Misc. Bul.* 144, pp. 321-326, pl. 1).—For several years a considerable number of specimens of *Prunus japonica* have been killed or disfigured by parasitic fungi. The disease is first indicated by the appearance of tear-like drops on the branches. These are sometimes solitary and in other instances numerous and more or less crowded. During damp or rainy weather the masses of gum are quite soft and gelatinous. In warm, dry weather the masses shrink and become horny, expanding again when moistened. At first the mass of gum is nearly colorless, but finally becomes black. When the masses are removed, irregular canker-like wounds, which sometimes extend to the pith, are present on the branches, and if such wounds are numerous the branch speedily dies.

The cause of this disease is a species of *Cladosporium*, morphologically indistinguishable from *C. epiphyllum*. The characteristics of the fungus and its growth are described at some length, and as preventive measures the author recommends spraying with a solution of potassium sulphid. Diseased branches should be removed, and lime thickly strewn on the soil under diseased plants.

Fruit diseases found along the Hudson, F. H. HALL, F. C. STEWART, and F. H. BLODGETT (*New York State Sta. Bul.* 167, popular ed., pp. 6).—This is a popular summary of Bulletin 167 of the station (see p. 154).

ENTOMOLOGY.

The codling moth, J. M. ALDRICH (*Idaho Sta. Bul.* 21, pp. 97-112, figs. 6).—The codling moth has been known in the Clearwater Valley since 1887, and in an untreated orchard near Moscow 21 per cent of the fruit was found to be infested. The length of the pupa stage of this insect in south Idaho is said to be about a week. In the region about Boise and Weiser there are at least 3 broods and a part of a fourth, while in Latah County there are 2 broods and a part of a third. Only a small portion of the late brood seems to survive.

Of 121 apples having the small marks of the third brood, selected in an orchard in Moscow in the month of November, only 20 were found to contain living larvæ.

The author conducted experiments in spraying, during which Paris green was applied in the Bordeaux mixture. The application was made within a week after the blossoms fell. On July 7 an examination was made to determine the effect of spraying. It was found that most of the worms which were destroyed were entering the calyx. On unsprayed trees an average of 16.7 worms entered the side of the apple, while on sprayed trees an average of 14.2 worms entered the apple in the same manner. There was a total saving of 12.3 apples per tree, and of these 9.7 were saved from worms which would have entered the calyx,

while only 2.5 per cent were saved from worms which would have entered the side of the apple. It therefore appears that 15 per cent of the worms entering from the side and 83 per cent of those attempting to enter the calyx were killed. It would seem, therefore, that the spray must be applied while it is still possible for the poison to enter the calyx cup in order to be most effective.

Observations were made upon the variation in the length of time during which the calyx remains open in different varieties of apples. This period varied from 6 to 10 days. The results obtained in Idaho would indicate that later applications of Paris green would be less effective than the first one, since only a small proportion of worms which attempted to enter the sides of apples were destroyed.

The author conducted experiments in banding trees for the purpose of catching the larvæ of the codling moth. Two bands of Canton flannel were placed 8 inches apart on the trunk of each tree. A table is given showing the number of worms caught during the different parts of the season. The highest record for a tree was 494 worms, and the average number of worms caught on 40 trees was about 215.

On one tree 5 bands were placed for the purpose of determining the relative proportion between worms which crawl down the trunk and those which fall to the ground and crawl up the trunk. Worms were caught under all the bands, and the experiment was therefore unsuccessful in keeping the worms separate. The upper band caught about twice as many worms as either of the intermediate ones and almost twice as many as the lower one, indicating that the great majority of worms crawl down the tree.

It would appear from these experiments that the majority of wormy apples which fall have no worms in them at the time, and that possibly the advantage derived from having hogs in the orchard for the purpose of eating windfalls has been overestimated.

The elms and their diseases, H. GARMAN (*Kentucky Sta. Bul.* 84, pp. 51-75, pls. 13).—The author gives brief notes on the appearance and distribution in the State of the following species of elms: *Ulmus americana*, *U. fulva*, *U. racemosa*, *U. alata*, *U. campestris*, and *U. montana*.

Among the white elms a serious disease has been observed since 1892. The first symptom of the disease is a loss of the leaves at the end of the twigs. As the disease progresses the foliage gradually falls from other parts of the tree until the tree is bare. Small, red, warty pustules, which represent a fungus, are often to be observed on the bark of these trees, but this fungus does not invade the wood of vigorous trees. The twigs are frequently attacked by the buffalo tree hopper, and the inner layer of bark was found to be eaten by a flat-headed grub which resembled the grub of the flat-headed apple-tree borer. In August, 1899, two white elm trees on the college grounds

were dug up and examined. One was dead, the other still alive. Under the bark of the living tree were found the grubs of *Magdalis armicollis*, *Saperda tridentata*, and the adults of *Hylesinus opaculus* were found making burrows preparatory to depositing their eggs.

The author believes, however, that insects are not the first cause of the disease. Attention is called to the fact that the habit of elm roots is to remain in the superficial layers of the soil, oftentimes mingling with the grass roots. From this fact it is apparent that any conditions which tend to impoverish the soil about the trunks of elm trees will gradually bring about a weakened condition of the trees. The trees will then be less able to resist the attacks of various insects and fungi.

The remedies suggested by the author are such as will help to replace the soil elements which are needed by the trees. A mulch of humus composed of dead leaves or other nutrient materials might supply the needed food and protect the soil from rapid evaporation and sudden changes in temperature. If it should be found that the beetles attack living and vigorous trees, it is recommended that the bark be coated with a whitewash containing Paris green or arsenate of lead. Dead and dying elm trees should be cut down and burned, in order to prevent the spread of injurious beetles.

The imported elm-leaf beetle (*Galerucella luteola*) is reported as occurring in large numbers and injuring English elms. American elms were comparatively free from the attacks of this insect. A brief description is given of the beetle in its various stages, together with notes on its habits and life history. For the attacks of this beetle the author recommends spraying with Paris green or arsenate of lead. The application should be made in the early spring as soon as the leaves unfold, and usually 3 sprayings should be sufficient. The larvæ and pupæ which accumulate at the base of the tree may be easily destroyed. Among the natural enemies of this beetle the author mentions the praying mantis and *Podisus spinosus*.

The elm-leaf skeletonizer (*Cunarsia ulmiarrosorella*) is reported as injurious to the white elm. Larvæ kept in breeding cages pupated either about the leaves or in the earth. The adults emerge during the latter part of March and in early April. Spraying with Paris green or arsenate of lead is recommended against this insect.

The elm-bark beetle (*Hylesinus opaculus*) was found in all diseased elms. The adults emerged from September 14 until October 15. The form of the burrows of this insect is described. The insect attacks elms only when they are badly diseased.

Insect attacks in 1899, R. S. McDougall (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 295-307, figs. 5).—*Cossus ligniperda* is reported as injurious to birches and poplars. A brief description of the insect in its various stages is given. The female

deposits its eggs in clusters in the cracks of the bark at the base of the tree. Isolated trees, or those along the edge of a woodland or an avenue, are most severely attacked. The complete life cycle of this insect extends over about 2 years. Protection against the deposition of the eggs may be afforded by the use of repellant substances painted upon the trunk of the tree.

The author gives notes on the habits, life history, and appearance of a number of species of the genus *Chermes*. Experiments were conducted on a plantation in Dunbar in the destruction of *Chermes*. The plantation consisted chiefly of larch, spruce, and pine. It was formed in 1893, and the young trees grew well until 1898, when they became badly infested with *Chermes*. Pure paraffin applied in a fine spray upon bright, clear days gave the following results: On April 15, 24 infested trees, chiefly larch and Scots pine, were sprayed with pure paraffin. On May 5 it was found that the aphides on the pine had been nearly all killed. The adult *Chermes* were destroyed, but the eggs were not much affected. On June 15, the eggs on the larch having already hatched, 24 trees were sprayed, and on June 30 it was found that they were effectively cleared of the pests. The young needles of the larch and spruce were slightly scorched by the spray, but during the season they grew fairly well. On June 9, a quarter of an acre of larch and spruce was sprayed with a solution of soft soap in the proportion of 1 lb. to a gallon of water. On June 30 the trees were found to be almost entirely free from insects. Some of the young shoots of the spruce were badly injured, but the larch escaped all damage.

An experiment with paraffin and sour milk dissolved in water gave results too irregular to be detailed. A paraffin emulsion was made of $\frac{1}{2}$ lb. of hard soap, 1 gal. of soft water and 2 gals. of paraffin, and this stock material was then diluted with 8, 10, 12, and 15 times its bulk of water. The strongest solution was found most effective.

Notes are given on the habits and injurious action of *Abraxas grossulariata*. This insect is injurious to the gooseberry, currant, apricot, plum, bramble, and blackthorn. The complete life cycle occupies 1 year. As remedies against this insect, the author recommends pruning the infested twigs and burning the parts removed as well as leaves and other rubbish upon the ground which might afford shelter for the caterpillars. The caterpillars may be destroyed by hellebore and paraffin emulsion. A solution of soft soap and quassia chips is also recommended with the following composition: Soft soap, 6 lbs.; quassia chips, 7 lbs.; and water, 100 gal.

The turnip flea-beetle (*Phyllotreta nemorum*) is described, and notes are given on its injurious habits. In combating this insect, the author recommends that the plants be well fertilized and that the ground be thoroughly cultivated. Cruciferous weeds in the neighborhood of cultivated plants should be destroyed.

Some miscellaneous results of the work of the Division of Entomology (*U. S. Dept. Agr., Division of Entomology Bul. 22, n. ser., pp. 109, figs. 28*).—This bulletin contains the following articles:

The two most abundant Pulvinarias on maple, L. O. Howard (pp. 7–23).—*Pulvinaria innumerabilis* is native to the United States and is found in all parts of the country. Its food plants are the silver-leaf maple, sugar maple, box elder, red mulberry, etc. In the latitude of Washington, D. C., the lice hatch the latter part of May and the early part of July. From young larvæ, which hatch July first, the first adult males issued on August 18. The females take up their winter station upon the twigs early in October. Formation of the egg sac begins about the middle of April. There is one annual generation.

Among the natural enemies of this insect the author mentions the English sparrow, *Chilocorus biterminalis*, *Hyperaspis signata*, *Dakruma coccidivora*, *Coccophagus lecanii*, *C. flavoscutellum*, *Atropates collinsi*, *Eunotus lividus*, *Aphycus pulvinariae*, and *Comys fusca*. Severe pruning is recommended soon after the hatching of the larvæ, and also spraying with kerosene soap emulsion or whale-oil soap.

Pulvinaria acericola is a native of the United States and has been reported from Indiana, Iowa, Tennessee, New York, Alabama, New Jersey, and Washington, D. C. Its food plant is *Acer saccharinum*. The eggs hatch in June. The larvæ molt twice, and late in October crawl upon the twigs where they hibernate. Toward the end of May the females migrate to the leaves and extrude their egg sac.

The natural enemies of this insect are *Hyperaspis signata*, *Aphycus hederaceus*, *A. flavus*, *Coccophagus fraternus*, *Pachyneuron altiscuta*, *Chiloneurus albicornis*, and *Leucopis nigricornis*.

The insects to which the name "kissing bug" became applied during the summer of 1899, L. O. Howard (pp. 24–30).—This article is essentially the same as that previously noted (*E. S. R.*, 11, p. 561).

An investigation to determine whether Melanoplus spretus breeds permanently in the Turtle Mountains of North Dakota, W. D. Hunter (pp. 30–37).—This article contains the itinerary of a trip made to investigate this subject. The author states that there are no places upon Turtle Mountains suitable for breeding grounds of this insect. The Rocky Mountain locusts, which have troubled the surrounding country, probably originated in the territory lying northeast of Regina toward the Big Touchwood Mountains. The observed locusts included *Melanoplus spretus*, *M. bivittatus*, and *M. packardii*. At New Rockford, N. Dak., *M. spretus* hatched out in considerable numbers, but gang plows were operated with such effect as to destroy the greater portion of them. The native species which have caused more or less serious losses in this region are *M. atlantis*, *M. bivittatus*, *M. packardii*, and *Dissosteira longipennis*.

The bronze apple-tree weevil, F. H. Chittenden (pp. 37-44).—*Magdalis ænescens* is reported as having attacked apple trees in the State of Washington. The varieties most injured are the Baldwin and Ben Davis; King of Tompkins, Northern Spy, and Bellflower being nearly free from infestation. This insect was found by A. D. Hopkins at Corvallis, Oregon, and has been reported by Jas. Fletcher from British Columbia. Notes are given on the life history and habits of the insect by C. V. Piper, who believes that the attack of this insect is made subsequent to injury caused by the fungus disease known as canker.

Two new Cecidomyiids destructive to buds of roses, D. W. Coquillett (pp. 44-48).—These insects, which are described as new species under the names of *Diplosis rosivora* and *Neocerata rhodophaga*, have been reported from Washington, D. C., New York, and New Jersey. The life history of the species is not known to the author. Rose growers have had considerable success in combating these insects with Persian insect powder, buhach, and refuse tobacco stems.

A new violet pest, D. W. Coquillett (pp. 48-51).—This insect is reported as attacking the leaves of sweet violets in Washington, D. C. The species has also been received from New York and Virginia. It is described under the name *Diplosis violicola*. The remedies which have been tried against the insect are hand picking of infested leaves and fumigation with hydrocyanic-acid gas.

Insects and the weather; observations during the season of 1899, F. H. Chittenden (pp. 51-64).—The author made observations on the effect of the cold winter of 1898-99 upon insects. He believes that the unusual severity of the weather was favorable to Northern insects but unfavorable to insects of Southern range. Notes are given on the apparent influence of the weather upon a considerable number of species of insects. The author concludes that the mean winter temperature has more effect in determining the rarity or abundance of insect species than has the mean summer temperature.

Food plants and injury of North American species of Agrilus, F. H. Chittenden (pp. 64-68).—Five species of this genus have been reported as injurious to birch, poplar, chestnut, oak, Lombardy poplar, raspberry, blackberry, and pear trees. *Agrilus anxius* caused considerable damage in parts of Buffalo, and Mr. M. F. Adams reported that the attacks of this insect were made subsequent to injuries produced by *Dryobates pubescens*. The insect has also been reported from Ann Arbor, Mich. One parasite (*Phasgonophora sulcata*) has been reared from this species. *Agrilus otiosus* feeds upon dogwood, butternut, and redbud. *A. bilineatus* is reported as injuring wild chestnut trees in Georgia. A list of 32 species of this genus is given, together with brief notes on their distribution and food plants.

Experiments with hydrocyanic-acid gas as a means of exterminating mealy bugs and other insect pests in greenhouses. H. D. Hemenway (pp. 69-78).—The author conducted a number of experiments with this gas in a wooden box and also greenhouse rooms. The cacti of the greenhouse were infested with *Diaspis cacti*. The room contained cacti, begonias, passifloras, bananas in fruit, etc. The mealy bugs, scales, and aphides were destroyed as well as a large percentage of the sow-bugs and earthworms.

In a house which contained carnations, smilax, violets, chrysanthemums, etc., and was infested with *Dactylopius destructor* and *Orthezia insignis*, 1 oz. of potassium cyanid was used to every 285 cubic feet. The insects were killed, but some of the plants were badly injured. The so-called "dilute method" of fumigation was tried in a camellia room, 1 oz. of potassium cyanid being used to every 3,000 cubic feet. It was fumigated at 6 o'clock p. m. The room was infested with green fly, mealy bug, and Fuller's rose beetle, and the plants in the room included coleus, azaleas, heliotropes, ferns, orange trees, etc. The insects were uninjured except part of the green flies. No damage was done to the plants. A number of other experiments were conducted, and the results are stated in tabular form.

Scale insects on American fruit imported into Germany (pp. 79-83).—An abstract of a paper by L. Reh, previously abstracted (E. S. R., 11, p. 655).

Insect control in Riverside, Cal., F. G. Havens (pp. 83-88).—The orange-growing section of Riverside comprises 12,500 acres of citrus orchards, and this region is one of the 3 divisions of Riverside County. This division is subdivided into 6 districts, and a local inspector has charge of each district. Each orchard is examined tree by tree, and a permanent record is kept by means of cross-lined paper. Besides inspection, the work of the insect-pest control includes eradication and quarantine. Very efficient methods of eradication have been devised and put into practice at Riverside. In 1898, 1,609 trees on 345 acres were infested with red scale. In 1899 the same orchards contained only 433 infested trees. The quarantine work has been so efficient that no insect pests have been introduced and become established since the existence of the horticultural commission.

Notes on a brief trip to Porto Rico in January and February of 1899. A. Busck (pp. 88-93).—A brief account of a trip to Porto Rico for the purpose of investigating the insect conditions of that colony. Notes are given on insects injurious to sugar cane, coffee, and tobacco. *Gryllotalpa hexadactyla* is reported as being exceedingly injurious to young tobacco plants. Large colonies of bees were frequently met with in hollow trees, and a considerable honey product is obtained from them. The article contains a list of the Coccidæ collected by the author and identified by T. Pergande and T. D. A. Cockerell.

Under the caption "General Notes" are given observations of an economic character upon a considerable number of injurious and other insects, as well as many notes from the various correspondents of the Division in different parts of the country.

The choice of colors by insects, F. PLATEAU (*Mem. Soc. Zool. France*, 12 (1899), No. 4, pp. 336-370).—A critical review is given of the literature of the subject. In investigating the question whether insects are guided in their choice of flowers by colors, the author made observations upon a considerable variety of insects, including, among others, species of *Megachile*, *Bombus terrestris*, *B. muscorum*, the honeybee, *Eristalis tenax*, *Papilio machaon*, etc.

To this question he makes a negative reply. It is admitted that insects may recognize at a distance the presence of flowers, but it is uncertain whether this recognition is due to the contrast between an area of flowers and their surroundings or to the odor of the flowers, or both. As soon as insects arrive among a group of flowers they seem to exercise no choice in the matter of color, but visit indifferently blue, red, yellow, white, or green flowers. If in a given species of plants the different floral variations in color exist in equal quantities, insects pass from flowers of one color to those of another without any discrimination. Occasionally the insects seem to prefer plants of one color for a short time and then pay more visits to flowers of another color. If in a group of flowers of a given species the floral variations in color are represented in unequal quantities, the number of insect visits to flowers of the different colors will be proportional to the number of flowers of these various colors.

Spraying notes, L. H. BAILEY ET AL. (*New York Cornell Sta. Bul.* 177, pp. 235-253).—Experiments were conducted in fighting San José scale on apple, pear, plum, almond, and willow trees. A 20 per cent mechanical mixture of kerosene and water was sprayed upon one lot of trees on April 10 and 11. Another lot of trees was sprayed on June 6, and all the trees were sprayed a second time on June 24. 3 especially dense trees receiving a third application on June 29. The young scale insects were abundant on young unsprayed currants by June 23. On examining the sprayed trees on December 11, few live scales could be found. On the smooth-barked willows all the scales were killed.

The authors believe that while fumigation may be a more thorough method than spraying, the San José scale may be held in check by spraying with kerosene. Fumigation will perhaps be found more desirable in nursery rows, but for use on growing trees spraying is believed to be "cheaper, simpler, and perhaps equally effective."

Some experiments were conducted with Paris green, Paragrene, Green Arsenite, XX, Pink Arsenoid, Green Arsenoid, Green Arsenoid

No. 53, and arsenite of lime. These insecticides were used in four different strengths, $\frac{1}{4}$ lb., $\frac{1}{2}$ lb., 1 lb., and $1\frac{1}{2}$ lbs. per barrel of 48 gals. Orchard application of these substances was made on June 10, while potatoes were sprayed on July 10 and 17.

Tables are presented showing the comparative effects of the 4 different strengths of the different insecticides upon foliage. A test was made of the insecticide value of these materials on potatoes. Two strengths of the substances were used, $\frac{1}{4}$ lb. and $\frac{1}{2}$ lb. to a barrel of 48 gals. Both strengths of Paris green, Paragrene, XX, and Green Arsenoid killed all the potato beetles, and nearly all the beetles were killed by both strengths of Pink Arsenoid, Green Arsenoid No. 53, and Green Arsenite.

Brief notes are given on the composition of various arsenical poisons. The authors find that no damage is done to foliage in spraying with $\frac{1}{4}$ lb. of the ordinary arsenites to the barrel, provided less than $3\frac{1}{2}$ per cent of soluble arsenic is present in the insecticide.

Attention is called to the importance of the specific gravity of various arsenical poisons in spraying. Considering the specific gravity of Paris green to be 10, other insecticides compare in weight as follows: Green Arsenite 10, Pink Arsenoid 9, Paragrene 7, Green Arsenoid 7, XX 4, Green Arsenoid No. 53, 4. Equal amounts of these arsenites shaken in water follow nearly the same order in settling, Paris green being first, and Green Arsenoid No. 53 last. Paragrene, Green Arsenite, Green Arsenoid, and arsenite of lime are all recommended as arsenical sprays. The comparatively high percentage of soluble arsenic in Green Arsenoid No. 53 makes this substance objectionable.

Experiments were conducted to determine the effect of copper carbonate and potassium sulphid on the foliage of Japanese plums, copper carbonate being used at the usual strength and potassium sulphid at the rate of 1 oz. to a gallon of water. Both substances were rather more injurious to the foliage than Bordeaux mixture. Where these substances were used too freely, the shot-hole effect upon the foliage was very noticeable.

The general conclusions of the authors may be stated as follows: The mechanical mixture of kerosene and water will probably displace kerosene and soap emulsion. In spraying with kerosene and water, early spring or late fall seem to be the preferable seasons. Paragrene, Green Arsenite, Green Arsenoid, and arsenite of lime are equal if not superior to Paris green. Unless lime is added, the simple solution of copper sulphate, 4 oz. to the barrel, can not be used without injury to the foliage.

The nature and use of certain insecticides, J. L. PHILLIPS and H. L. PRICE (*Virginia Sta. Bul.* 97, pp. 7-26).—The authors describe and give brief notes on the common arsenical, contact, and tracheal insecticides and on the methods of their application. Experiments

were tried upon 25 plats of potatoes with various arsenical poisons in aqueous solution, for the purpose of determining the effectiveness of these insecticides in killing the potato beetle, and also their effect upon the foliage of the potato. The results of these tests may be tabulated as follows:

Effect of insecticides on potato beetle and foliage.

Insecticide.	Amount per 100 gal. of water.	Effect on beetles.	Effect on foliage.
London purple	1 lb	Killed nearly all the beetles ..	No damage.
Paris green	1 lb	do	Do.
Paragrene	2 lbs	do	Do.
Do	1 lb	do	Do.
Do	$\frac{1}{2}$ lb	Some beetles escaped	Do.
Special laurel green	6 lbs	Killed all the larvæ	Foliage badly damaged.
Do	4 lbs	do	No damage.
Do	1 lb	Some beetles escaped	Do.
Green Arsenoid	2 lbs	Killed all the beetles	Do.
Do	1 lb	Killed nearly all the beetles ..	Do.
Do	$\frac{1}{2}$ lb	A few beetles escaped	Do.
White Arsenoid	2 lbs	Killed nearly all the beetles ..	Slight damage.
Do	1 lb	Many beetles escaped	No damage.
Do	$\frac{1}{2}$ lb	A large proportion of the beetles escaped.	Do.
Pink Arsenoid	2 lbs	Killed all the larvæ	Slight damage.
Do	1 lb	do	No damage.
Do	$\frac{1}{2}$ lb	Several larvæ escaped	Do.
White Arsenate	2 lbs	Killed only a few beetles	Do.
Do	1 lb	do	Do.
Swift's Arsenate of Lead	8 lbs	Killed all the larvæ	Do.
Do	4 lbs	do	Do.
Do	2 lbs	Small proportion of beetles escaped.	Do.
Parine green	2 lbs	Killed all larvæ	Do.
Do	1 lb	do	Do.
Do	$\frac{1}{2}$ lb	Small proportion of larvæ escaped.	Do.

Experiments were tried in spraying fruit trees with pure kerosene and with the kerosene-water mixture. The results which were obtained indicate that "pure kerosene can be used on all our fruit trees in the dormant season and with proper precaution during the growing season also, except on peach. Water mixtures have with us proved as dangerous as pure kerosene. This substance should be used on trees only in cases of necessity."

The pea louse (*Nectarophora destructor*) is reported as having caused considerable damage in various parts of the State. A number of experiments were conducted with different insecticides in combating this insect. The insecticides which were used were Good's No. 6 tobacco-potash soap and a kerosene-water mixture. From these experiments it was found that soap solutions in the proportion of 1 lb. to 6 or 8 gal. of water, although very effective in killing the lice, caused injury to the foliage. Soap solutions at the rate of 1 lb. to 10 or 12 gal. of water were not so destructive to the lice but caused no injury to the plants. In their experiments the authors found that considerable damage was done to the foliage by the kerosene-water mixture, and this substance is, therefore, not recommended for spraying peas.

The queen bee, A. GALE (*Agr. Gaz. New South Wales*, 11 (1900), No. 3, pp. 204-206, figs. 6).—The author gives descriptions of the method of formation and appearance of queen cells, and illustrations are given of these cells as built under different conditions.

Sericulture in Austria during the last 50 years, G. BOLLE (*Atti e Mem. Ital. R. Soc. Agr. Gorizia*, 40 (1900), No. 1-2, pp. 29-39, figs. 7).

Beetles injurious to fruit-producing plants, O. LUGGER (*Minnesota Sta. Bul.* 66, pp. 83-332, figs. 249).—This bulletin contains a brief classification of the various families of beetles and a general account of a large number of species which are known to be injurious to fruit trees and small fruits. In most cases the approved remedies are suggested for treatment of these insects.

Insect damage to spruce timber in Maine and New Hampshire, A. CAREY (*Forester*, 6 (1900), No. 3, pp. 52-54).—In northern Vermont and New Hampshire outbreaks of forest insects occurred about 30 years ago, and also about 15 years ago. During investigations which were carried on to determine the cause of the unusual death of spruce timber at the present time, it was found that the damage was due to the attacks of *Dendroctonus polygraphus* var. *rufipennis*.

Wood-boring caterpillars, H. FAES (*Chron. Agr. Canton Vaud*, 13 (1900), No. 5, pp. 104-110, figs. 2).—Notes on the habits and life history of *Cossus ligniperda*, *Zeuzera xesculi*, and *Trochilium apiforme*.

Some insect notes, F. M. WEBSTER (*Ent. News*, 11 (1900), No. 4, pp. 436-439).—Notes on *Halticus uhleri*, *Crioceris 12-punctata*, *Oberea bimaculata*, and *Cecidomyia destructor*.

The forest tent caterpillar, E. P. FELT (*Country Gent.*, 65 (1900), No. 2459, p. 217).—Brief notes on the effect of the depredations of these insects upon the quality of maple sugar.

The occurrence of a plant louse on the roots of sugar beets, P. DOERSTLING (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 1, pp. 21, 22).—The author reports that a species of aphid appeared in large numbers on the roots of sugar beets during the autumn of 1899. The plant lice were also observed on the under side of the leaves. The damage to sugar beets is estimated at from 30 to 40 per cent in different fields. The species of plant lice was not identified.

Aspidiotus diffinis, C. L. MARLATT (*Ent. News*, 11 (1900), No. 4, pp. 425-427).—This scale insect was probably introduced from Europe. It has been reported as infesting basswood in Canada, and it appears that *A. jatrophae* is a synonym of this species. The insect is found in large numbers on basswoods in Ontario and may perhaps become a species of considerable economic importance. A brief bibliography is added to the article.

A new genus of Atropidæ, N. BANKS (*Ent. News*, 11 (1900), No. 4, pp. 431, 432).—*Psocinella slossonæ* is described as a new genus and species of this family. The species is reported as attacking butterflies in a collection and may prove to be a museum pest.

Cytodites nudus in the common fowl, E. V. WILCOX (*Contrib. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 5, pp. 147-153, fig. 9).—A brief discussion of the literature concerning this mite, together with notes on its occurrence in Montana.

The species of the orthopteran genus Derotmena, S. H. SCUDDER (*Proc. Amer. Acad. Arts and Sci.*, 35 (1900), No. 19, pp. 385-395).—A monographic account of this genus.

Metzneria lappella, T. W. FYLES (*Canad. Ent.*, 32 (1900), No. 1, pp. 15, 16).—This European species is reported as feeding on the heads of burdock.

Phylloxera and the diseases of the vine, V. THIEBAUT (*Prog. Agr. et Vit.*, 17 (1900), No. 12, pp. 365-367).

Phylloxera in Switzerland, B. H. RIDGELY (*U. S. Consular Rpts.*, 62 (1900), No. 234, pp. 298, 299).—Attention is called to the seriousness of the phylloxera problem

in the Canton of Vaud and a brief report is given of the action of the Canton Council of State at Lausanne in recommending the extensive use of American vines.

A new remedy for phylloxera, J. DUFOUR (*Chron. Agr. Canton Vaud*, 13 (1900), No. 2, pp. 29-34).—Soot has recently been proposed as a new remedy for this insect. The author calls attention to the fact that many previous experiments have been made with this substance without success.

Phytoptus vitis (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 2, p. 103).—It is recommended that in infested vineyards all dry leaves and rough bark be burned at the end of the season.

A peculiar organ which occurs in Poecilocerus socotranus, H. A. KRAUSS (*Zool. Anz.*, 23 (1900), No. 610, pp. 155-167, fig. 4).—The author has discovered an organ in the pronotum of this grasshopper which seems to have a phosphorescent function, or at least to be analogous to phosphorescent organs of other insects.

The gypsy moth (*Porthetria dispar*), S. LAMPA (*Ent. Tidskr.*, 21 (1900), No. 1, pp. 34-46, pl. 1).—Descriptions are given of the eggs, larvæ, pupæ, and adult males and females of this species, together with notes on its habits and life history. Brief reference is made to the work which was carried out in the southeastern part of Sweden in fighting the gypsy moth. The government appropriated \$2,800 for this purpose. A brief note is also given on the natural enemies of the gypsy moth.

On the molt of pupæ in *Pterophorus*, T. A. CHAPMAN (*Entomologist*, 33 (1900), No. 442, pp. 82-85).—The author made observations especially on the pupation of *P. galactodactylus*. The species pupates beneath a leaf. The molt took place in 3 observed examples about 1 o'clock p. m., after 2 days of quiescence. The larvæ holds on to the leaf by the anal prolegs only. Molting takes place rapidly and is accomplished in about 15 minutes.

Depredations of the cottony maple scale, C. E. BROWN (*Bul. Wisconsin Nat. Hist. Soc.*, n. ser., 1 (1900), No. 1, pp. 65-67).—*Pulvinaria innumerabilis* occurred in unusual numbers in Wisconsin notwithstanding the severity of the previous winter. In Milwaukee the trees were subsequently attacked by the tussock moth.

The pear and cherry tree slug, A. M. LEA (*Agr. Gaz. Tasmania*, 7 (1900), No. 8, p. 176).—Brief notes on the habits, life history, and means of combating *Scalandria cerasi*.

The deposition of the eggs of *Tortrix ambiguella*, J. PERRAUD (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 3, pp. 80-83).—The female lays about 4 or 5 eggs on each grape.

The action of environment on the development of *Tortrix ambiguella*, J. PERRAUD (*Prog. Agr. et Vit.*, 17 (1900), No. 13, pp. 391-393).—The author discusses the influence of climatic and other conditions upon the observed alternation of periods of relative abundance and scarcity of this insect. With the present knowledge of the problem, it seems to be impossible to indicate accurately the determining factors of the variation in numbers.

The spiny elm caterpillar, C. M. WEED (*New Hampshire Sta. Bul.* 67, pp. 123-141, figs. 13).—A popular account of the habits, life history, and natural enemies of *Vanessa antiopa*, with brief notes on remedies to be applied against this insect. The species is said to have been unusually abundant on elm trees during the past 3 years in New Hampshire. It is believed to be single-brooded in the State.

Spraying tall trees, P. MACMAHON (*Queensland Agr. Jour.*, 6 (1900), No. 2, pp. 118, 119, pl. 1).—The author gives brief notes on kerosene emulsion, resin wash, London purple, Bordeaux mixture, and Eau celeste. Experiments were made in spraying tall trees which were infested with *Ceroplastes rubra*. An upright post was securely fixed in the spray wagon, and to this post a long bamboo rod which supported the hose was so attached that it could be readily directed toward the desired part of the tree.

The application of Sanatol, E. KRÜGER (*Ztschr. Vet.*, 12 (1900), No. 3, pp. 124, 125).—Sanatol has been recommended for gross disinfection and as a deodorizer and repellant of flies. Experiments were conducted in which stalls were sprayed with a 1 per cent aqueous solution of Sanatol. This application had a striking effect in repelling the flies from the stable.

Carbon bisulphid, E. PERRONCITO (*Gior. R. Soc. Accad. Vet. Ital.*, 49 (1900), No. 4, pp. 75-79).—The author calls attention to the great value of this substance in fighting phylloxera and states that its antiseptic power is not very great. Spores of the anthrax bacillus survived an exposure to this substance of 49 days' duration.

Treatment with bisulphid of carbon, J. DEFOUR (*Chron. Agr. Canton Vaud*, 13 (1900), No. 5, pp. 89-101, figs. 2).—A general account of the nature and action of carbon bisulphid, together with detailed directions for its use in combating phylloxera.

The use of arsenical salts as insecticides, H. GROSJEAN (*Prog. Agr. et Vit.*, 17 (1900), No. 14, pp. 410-414).

Inspection of Paris green, W. C. STUBBS and W. T. JONES (*Louisiana Stas. Bul.* 58, pp. 265-276).—This includes the text of the State law providing for the inspection of Paris green, and a brief report on the operation of the law, with analyses of 38 samples of Paris green.

The entomologists' directory, H. SKINNER (*Philadelphia: American Entomological Society*, 1900, pp. 84).—This directory contains the names, addresses, and special departments of study of the entomologists in the United States and Canada, together with a geographical arrangement of the names, a list of entomological societies, their secretaries, and the official entomologists of the agricultural colleges and experiment stations.

FOODS—ANIMAL PRODUCTION.

Dietary studies of university boat crews, W. O. ATWATER and A. P. BRYANT (*U. S. Dept. Agr., Office of Experiment Stations Bul.* 75, pp. 72).—With a view to studying the effects of muscular work on food consumption, dietary studies were made with the Harvard University and Freshman boat crews when training at Cambridge and before the races at Gales Ferry; with the Yale University crew at New Haven and Gales Ferry, and with the captain of the Harvard Freshman crew at Gales Ferry. The results of the studies are summarized in the following table:

Summary of results of dietary studies of university boat crews.

[Nutrients in food actually eaten per man per day.]

	Protein.	Fat.	Carbo- hydrates.	Fuel value.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Calories.</i>
Harvard University crew at Cambridge	162	175	449	4,130
Harvard Freshman crew at Cambridge	153	223	468	4,620
Yale University crew at New Haven	145	170	375	3,705
Harvard University crew at Gales Ferry	160	170	448	4,075
Harvard Freshman crew at Gales Ferry	135	152	416	3,675
Yale University crew at Gales Ferry	171	171	434	4,070
Captain of Harvard Freshman crew	155	181	487	4,315
Average	155	177	440	4,085

The results are discussed and compared with the results of dietary studies with athletes, college clubs, mechanics, farmers, and professional men, and with the commonly accepted dietary standards.

Milk protein as a food, BACKHAUS and R. BRAUN (*Ber. Landw. Inst. Univ. Königsberg*, 5 (1898-99), pp. 34-60).—A number of feeding experiments with dogs and rabbits and digestion and metabolism experiments with rabbits on the value of the casein of skim milk are reported. Casein was precipitated in different ways. The authors' principal conclusions were in effect as follows: Protein is supplied more cheaply by milk than by almost any animal or vegetable food material. The feeding experiments reported show that milk protein is almost completely digested, and that it is capable of supplying the protein requirements of animals for long periods. The insoluble casein possessed the same nutritive value for this purpose as the soluble casein salts. Nevertheless, the preparation of such soluble salts is of importance, since they may be conveniently used for many purposes. Judging by the experiments carried on a simple method, which at the same time gives good results, consists in precipitating the milk protein with hydrochloric acid, having previously warmed the milk, carefully washing the precipitate, and drying it at a low temperature, and mixing the finely ground powder with salts, which render it soluble. For this latter purpose sodium citrate is especially valuable, since it has no taste, while sodium phosphate is valuable from a physiological standpoint on account of the phosphorus with which it supplies the body. Sodium borate is valuable on account of its antiseptic properties. A mixture of these salts is regarded as preferable to either alone.

Commercial feeding stuffs in New York, W. H. JORDAN and C. G. JENTER (*New York State Sta. Bul.* 166, pp. 233-273).—The New York law regarding the sale and analysis of commercial feeding stuffs is quoted, the value of such feeding stuffs discussed, a classification suggested, and a report made of a large number of analyses of samples collected in 1898 and 1899, including the following:

Cotton-seed meal, cotton-seed feed, linseed meal (old and new process), gluten meal ('M' and Chicago), gluten feeds (Buffalo, Climax, Davenport, Diamond, Joliet, 'R,' Peoria, Empire, Waukegan, Davenport corn feed, and 2 gluten feeds without special name), malt sprouts, brewers' grains from lager beer and from ale, distillery waste, buckwheat middlings, buckwheat feed, buckwheat ships, wheat bran, ship stuff, wheat feeds (Royal, Buckeye, King Winter Wheat, New England mixed, and middlings from different grades of flour and wheat), hominy feed, hominy meal, huds-nuts, H-O standard dairy food, H-O standard horse food, H-O feed, Quaker oats, Victor feed, Victor corn and oats, corn and oat feed, chop feed, H-O defi feed, X oat feed, Schumaker's stock food, corn, oat, and barley feed, wheat feed, pea meal, malt skimmings, rye feed, scorched wheat sugar-corn feed, starch feed (wet and air dry), gluten feed (wet and air dry), and Clover meal.

The carbohydrates of mixed feeds and other feeding stuffs are discussed, special attention being called to the superiority of the dry

matter of cereal grains over that of coarse fodders. The carbohydrates in a number of different feeding stuffs is reported:

Carbohydrates in dry matter of several feeding stuffs.

	Sugars and starch.	Total nitrogen-free extract.	Sugars and starch in nitrogen-free extract.	Digestibility of the nitrogen-free extract.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Cotton-seed meal.....	16	27.9	57.4	50
Linseed meal (old process)	13.2	39.2	33.7	78
Linseed meal (new process).....	20.8	40.8	51	84
Gluten meal	38.2	49.8	76.7	93
Buffalo gluten feed	27.3	58.3	46.8	84
Davenport gluten feed.....	29.8	60.9	48.9
Diamond gluten feed	31.6	61.6	51.3
Joliet gluten feed	34	66	51.5
Peoria gluten feed	28.9	59.8	48.3	90
Malt sprouts	23.1	49.6	46.6	69
Buckwheat middlings.....	27.3	48.3	56.5

H-O dairy feed.....	34.6	60.4	57.3
Oat feed	29.4	61.5	47.8	60
Victor feed.....	43	70.3	61.2
Chop feeds.....	47.5	73.5	64.6
X oat feed	16.1	57.9	27.8

"Many of the materials mentioned above when compared with the grains from which they are derived show a depletion of sugars and starch and a corresponding relative increase in the nitrogen-free extract of the less valuable compounds. This is especially true of the wheat offals, the gluten feeds, and the oat feed mixtures. In the case of the one sample of gluten meal examined the starch still constituted a large proportion of the nitrogen-free extract. The chop feeds and other similar combinations contain as a rule quite a proportion of corn, that furnishes nearly all the starch which is found in these mixtures. . . .

"These facts are in harmony with the outcome of digestion experiments, from which we learn that the nitrogen-free extract of the whole grains is much more digestible than that of most of the manufacturing wastes which come from them. . . .

"Some 'mixed feeds' apparently are compounded and advertised on the assumption that feeding stuffs are to be compared in value solely on the basis of their percentage of protein and fat. This is a false basis. The quality of the accompanying carbohydrates must always be considered. For instance, it would not be difficult to simulate the composition of corn meal or of wheat middlings by mixing oat hulls with some of the old-style linseed meal, adding a little crushed linseed to make up the deficiency of fat. But would the mixture equal corn meal in value? By no means. In one case the protein and fat would be associated with woody fiber in large proportion, and in the other case with little else than starch. The net value of the corn meal would be much above that of the mixture as measured by the extent and labor of digestion."

The various oat feeds, proprietary, and other mixed feeds are discussed at some length and appear, in the authors' opinion, to contain an undue proportion of crude fiber, the proportion of oat hulls being larger than the oat kernels present.

"Some of them must contain not less than 50 lbs. of oat hulls per 100 lbs. . . .

"In certain brands an amount of some highly nitrogenous feeding stuff like cotton-seed meal or gluten meal is found, the object of its use being to bring up the protein content to the standard of wheat bran. This certainly improves the feed, but at the

same time the presence of high-quality ingredients adds nothing to the value of the inferior constituents. Grinding corn with oat hulls, for instance, may not injure the corn, but it does not improve the hulls. They are still hulls and retain all their characteristics as a feeding stuff."

In order to study the effect of introducing oat feeds into grain rations, a digestion experiment was made with sheep, one of the commercial oat feeds sold in New York being used. The average coefficients of digestibility obtained were as follows: Dry matter 58, organic matter 59.5, protein 82.5, fat 92, nitrogen-free extract 60.5, and crude fiber 33 per cent.

This result was compared with the average coefficients of digestibility of whole oats and maize, the comparison showing in the authors' opinion that whole oats furnished about 12 per cent and maize 31 per cent more total nutritive material than the oat feed. Besides the material including the entire grain is of better quality, being made up more usually of protein and the easily digested carbohydrates.

The authors also report the analysis of a number of condimental feeding stuffs.

"In these mixtures were found, as the principal constituent, some common feeding stuff like bran or other wheat offals, corn offals, linseed meal, and so on. The special ingredients added ostensibly for medicinal effect, were found to include charcoal, fenugreek, gentian, sulphur, salt, saltpeter, sodium sulphate, iron compounds, and pepper.

"Particular attention is called to the prices at which these 'foods' are sold. The range is from \$100 to \$500 per ton, which is at least from \$70 to \$470 per ton more than the materials are worth for food purposes. It may be claimed, as some of the manufacturers urge, that these mixtures should be regarded as medicines. Even if this is true the farmer who wishes to administer any of these common substances to his animals can do so at a small fraction of their cost in condimental foods by purchasing them as drugs and then mixing them with the grain ration as he wishes. For the promoters of these mixtures to claim that they have any knowledge of compounds and compounding not common to veterinary medicine is charlatanism in its most offensive form."

On the influence which the kind and amount of food exercises upon the amount of metabolism and the power to perform work, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 77 (1899), No. 9-10, pp. 425-482).—The author reports a number of experiments with cats and dogs. In some cases the balance of income and outgo of nitrogen was determined, as well as the respiratory quotient. Experiments were made under different conditions of feeding and fasting.

The experiments are discussed in relation to the early work of Bidder and Schmidt,¹ and the theories of nutrition and the production of energy promulgated by Voit and his followers. The author's principal deductions follow:

The addition of protein to a maintenance ration caused an increase in metabolism and the productive power. Further, it caused an increase

¹ Abstracted in U. S. Dept. Agr., Office of Experiment Stations Bul. 45.

in the body weight due to an increase in cell substances. This increase of cell substance under favorable conditions can be induced until the body weight is doubled. Metabolism and productive power of the body increased in direct proportion to the increase in body weight induced by protein. The highest metabolism and the greatest productive power can therefore be induced only by the most abundant supply of nitrogen in the food. Each diminution of the daily supply of protein caused a decrease in the metabolism and productive power, even if the protein omitted was replaced by an amount of fat and carbohydrates calculated to supply the same amount of energy. An increase in the amount of fat or carbohydrates in the diet did not cause an increase in metabolism or in the power of the body considered as a machine. Protein added to the diet replaces in the metabolism of the body a quantity of fat possessing the same force value, provided, of course, that the diet to which the protein is added contains fat, etc., as well as protein. The laws of the metabolism of protein are the same in dogs and cats. No formation of fat from protein in the animal body, as insisted upon by Voit and Cramer, was observed. Man can not be nourished by protein alone, since it would be impossible to digest the amount which would be required. According to the investigations of the author and his pupils, a young man instinctively uses an amount of protein which is sufficient for about one-fifth of the total productive power of the body. Man can digest much more protein, but it seems necessary to assume that for omnivora the protein consumed should not exceed a certain limit. This is not proven, but man instinctively refrains from an exclusive meat diet.

Concerning direct and indirect calorimetric measurements with animals in a study of nitrogen equilibrium when fasting and fed after fasting, P. P. AVROROV (*Russ. Arch. Patol. Klin. i Bakt.*, 7 (1899), p. 430; *abs. in Physiologiste Russe*, 1 (1899), No. 15-20, pp. 304-306).—A number of experiments with dogs are reported. Some of the principal conclusions follow. The metabolism of matter and the production of heat takes place in animals with remarkable regularity and uniformity when the experimental conditions are as uniform as possible. The intensity of the metabolism of matter and the production of heat in dogs is inversely proportional to the size of the animal and directly proportional to the surface area. On an average during the period of fasting the cleavage of fat was greatly diminished, while the cleavage of proteids was reduced to a minimum. The heat produced was diminished 15 or 16 per cent and the production of carbon dioxid was diminished from 21 to 22 per cent. Gains in protein were made after fasting with little or no effect upon the production of heat. The albumin of the living tissues of the body did not differ as regards its potential energy from the albumin of the meat fed. The production of heat was found to be closely connected with the excretion

of carbon dioxid. As shown by comparison, the results obtained directly with the calorimeter and those obtained indirectly by calculation from the data of metabolism experiments agreed very closely. Other conclusions are drawn which have to do with feeding after fasting.

Steer feeding, R. H. McDOWELL (*Nevada Sta. Bul. 41, pp. 6, pls. 6*).—With a view to learning the amount of alfalfa hay required for a pound of gain, 4 steers were fed from December 11, 1897, to May 9, 1898. From the beginning of the test to March 2 they were given alfalfa hay only, and from that date until May 9 cracked corn was fed in addition to the hay. The steers had been on pasture without grain previous to the test. During the test they were fed in box stalls. The average results for the 2 periods follow:

Results of feeding steers alfalfa hay with and without grain.

	Weight at begin- ning of test.	Period No. 1.		Period No. 2.		
		Gain in weight.	Alfalfa hay eaten per pound of gain.	Alfalfa hay eaten.	Cracked corn eaten.	Gain in weight.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Steer No. 1.....	1,350	95.0	21.7	1,928.25	27.2	120.0
Steer No. 2.....	1,160	102.5	23.2	1,975.40	140.0	137.5
Steer No. 3.....	1,230	112.5	20.3	1,229.90	13.3	37.5
Steer No. 4.....	1,090	145.0	15.1	2,006.00	20.3	74.0

Two days after the close of the test steers Nos. 3 and 4 were slaughtered, the dressed weight being 56.6 and 56.49 per cent, respectively, of the live weight. Steer No. 1 was fed until December 2, gaining in this time 247.5 lbs. and consuming 6,262.25 lbs. of alfalfa hay, 174.5 lbs. of cracked corn, and 655.3 lbs. of bran. The dressed weight was then found to be 61.7 per cent of the live weight. The feeding was continued with steer No. 2 until May 7. In this time there was a gain of 50 lbs., 473.9 lbs. of hay and 104.5 lbs. of cracked corn being consumed. The dressed weight of this steer was found to be 55.9 per cent of the live weight.

Sheep-feeding experiments at Leswalt, A. P. AITKEN (*Trans. Highland and Agr. Soc. Scotland, 5. ser., 12 (1900), pp. 23-46*).—Continuing previous work, the author reports a test, conducted at Leswalt, of the value of turnips alone and supplemented by different concentrated feeds for sheep. The test, which was made with 6 lots of 20 sheep each, began November 19, 1898, and covered 19 weeks. It was divided into 2 periods of 9 and 10 weeks, respectively. All the lots were fed turnips. In addition, lot 2 was fed maize, lot 3 oats, lot 4 equal parts of oats, dried distillery grains, and linseed cake, lot 5 dried distillery grains, and lot 6 linseed cake. During the first half of the test half a pound per head daily of the concentrated feeding stuffs was fed. During the latter half of the test the oats and maize

were increased to about $\frac{3}{4}$ lb. and the other feeds in proportion to their cost. At the close of the test the sheep were slaughtered and judged by an expert. The average results for the whole test follow:

Turnips with and without concentrated feeds for sheep.

	Weight of lot at beginning of test.	Average gain per head per week.	Average weight of carcass.	Average weight of tallow.	Average weight of skins.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Lot 1 (fed turnips)	1,387	1.31	48.9	4.5	13.1
Lot 2 (fed turnips and maize)	1,397	1.80	58.3	5.6	14.7
Lot 3 (fed turnips and oats)	1,423	1.35	53.2	5.6	14.1
Lot 4 (fed turnips, oats, dried distillery grains, and linseed cake, 1:1:1)	1,405	2.01	58.4	5.3	15.0
Lot 5 (fed turnips and dried distillery grains)	1,438	2.33	62.8	6.7	16.6
Lot 6 (fed turnips and linseed cake)	1,377	1.78	58.4	5.0	15.0

According to the author, the most satisfactory gains were made by lots 5, 4, and 6, in the order named. Lot 3 ranked fifth, the results not being very different from those obtained with lot 1, which received no concentrated feeding stuff. In the opinion of the expert who judged the carcasses, lot 2 was the most satisfactory and lot 6 next.

Pig feeding, R. H. McDOWELL (*Nevada Sta. Bul. 40, pp. 16*).—The value of alfalfa hay when fed alone and when fed with turnips and with roots, corn, and peas was tested with 4 grade Poland-China pigs divided into 2 lots of 2 each.

From December 12 to January 2 both lots were fed alfalfa hay only, consuming a little over 99.1 lbs. per lot. Lot 1 weighed 262.5 lbs. at the beginning of the test and lot 2, 297.5 lbs. Lot 1 lost 32.25 lbs. and lot 2, 51 lbs.

From January 2 to January 23 both lots were fed turnips and alfalfa hay, consuming 266 lbs. of turnips per lot in addition to some 90 lbs. of alfalfa hay. During this time lot 1 gained 15.25 lbs. and lot 2, 13.75 lbs. From January 23 to March 6 lot 1 was given 121.1 lbs. of peas in addition to 86.4 lbs. of alfalfa hay and 863.5 lbs. of turnips and lot 2 121.1 lbs. of corn in addition to 90.9 lbs. of alfalfa hay and 866 lbs. of turnips. The gains of the 2 lots were 94.75 and 82.75 lbs., respectively.

From March 6 to March 16 lot 1 consumed 5.8 lbs. of hay, 19 lbs. of sugar beets, and 102 lbs. of peas and gained 19.75 lbs. From March 6 to March 22 lot 2 consumed 5.9 lbs. of alfalfa hay, 163 lbs. of sugar beets, and 187 lbs. of corn, gaining 62.5 lbs.

An appendix to the bulletin contains answers received from farmers to a number of questions regarding the feeding of alfalfa to pigs.

Experiments in feeding pigs for the production of pork, H. J. PATTERSON (*Maryland Sta. Bul. 63, pp. 41, pls. 10, dgm. 2*).—Statistics of the pig-raising industry in Maryland are given, and 12 tests with pigs are reported in which different feeding stuffs were compared.

Two lots of pigs about 8 weeks old were fed for 165 days to compare separator skim milk with a quantity of green clover furnishing approximately the same amount of protein. Both lots had a basal ration of corn and cowpea meal, linseed and gluten meal, 8:1:1. The average daily gain per pig in the lot fed skim milk was 1.26 lbs., and in the lot on clover, 0.6 lb., the cost of a pound of gain in the 2 cases being 4.09 and 3.7 cts., respectively. The pigs were slaughtered at the close of the test, the heaviest weighing over 200 lbs. dressed. On the basis of his results the author calculates that green clover is worth \$2 per ton, and separator skim milk 14 cts. per hundredweight.

Separator skim milk was compared with gluten and linseed meal for balancing a grain ration, using 2 lots of 6 pigs each. Both lots were fed a basal ration of hominy chop and ground-corn shives during the test which covered 121 days. The average daily gain of the pigs fed the ration containing skim milk was 1.54 lbs., and of the pigs fed the ration containing gluten and linseed meal, 1.12 lbs. The cost of a pound of gain in the 2 cases was estimated at 3.5 and 2.51 cts., respectively.

Four tests are reported with young pigs weighing from 36 to 61 lbs. each on the value of ground-corn shives, *i. e.* "new corn product." This material was fed as a partial substitute for hominy chop in the first test, as a substitute for part of the mixed-grain ration in the second test, as an addition to grain and skim milk in the third test, and in the fourth test as a partial substitute for hominy chop, with linseed meal and gluten meal during the last 3 months of a 5 months' trial. Skim milk formed part of the ration in every case. In the first of these tests the average daily gain per pig on the ration with corn shives was 1.37 lbs.; on the ration without corn shives, 1.43 lbs. The author calculates that the ground-corn shives were worth from \$3.40 to \$6.58 per ton, as shown by the returns in pork. The cost of this material is stated to be \$11 per ton. In the second test the average daily gain per pig on the ration containing corn shives was 1.3 lbs.; on the ration without corn shives, 1.63 lbs.; the cost of a pound of gain in the 2 cases being 2.96 and 2.57 cts. In the third test the average daily gain per pig of the lot fed the ration without corn shives was 0.81 lb.; the cost of a pound of gain, 3.21 cts. The average daily gain per pig in the lots fed corn shives varied from 0.87 to 0.94 lb. and the cost of a pound of gain from 3.26 to 3.36 cts., the largest gain but at the greatest cost being made on the ration containing the least amount of corn shives.

In the fourth trial the average daily gain per pig in the 2 lots fed a ration with linseed meal during the first period was 0.99 and 0.98 lb., respectively, the cost of a pound of gain being 2.7 cts. The average daily gain of the 2 lots fed during the same time a ration with gluten meal was 0.8 and 0.85 lb., respectively, the cost of a pound of gain

in each case being 2.13 cts. When corn shives was substituted for part of the hominy chop in the linseed-meal ration during the second period, the average daily gain was 0.73 lb. per pig, as compared with 0.53 lb. in the lot receiving no corn shives. The cost of a pound of gain in each case was 4.56 cts. When corn shives were substituted for part of the hominy chop in the gluten-meal ration in the second period, the average daily gain per pig was 0.78 lb. as compared with 0.85 lb. for the lot receiving no corn shives, the cost of a pound of gain being 2.91 cts. in both cases.

Though the method is not explained, the author makes the following calculation:

“With the linseed ration the fodder [ground-corn shives] showed an estimated value of \$28 per ton, and with the gluten ration an estimated value of \$20 per ton. If the fodder is not taken into consideration, the average cost for producing 100 lbs. of gain with the linseed ration was \$4.18, and with the gluten ration \$2.70.”

The value of cowpea pasture, artichoke pasture, and sweet potatoes in addition to a ration of grain and skim milk with and without corn shives was tested with 6 lots of 5 pigs each. Lot 1 was fed ground-corn shives, grain, and during the last 4 months of the test skim milk also; lot 2 was fed the same ration except that for the last 2 months of the trial sweet potatoes and sweet-potato strings were fed. Lots 3 and 4 were fed the same ration as lot 1 for part of the test, and were then pastured on cowpeas from 2 to 4 weeks, and finally were given the run of a plat of artichokes. Lots 5 and 6 were fed at first a ration of grain and skim milk; later lot 6 was turned into a cowpea pasture, and, during the last month of the test, was fed sweet potatoes in addition to gluten meal and skim milk. Lots 1 and 2 were fed 5 months, lots 3 and 4, 4 months, and lots 5 and 6, 3 months. The average gain of the pigs in lot 1 was 108.8 lbs., and the cost of a pound of gain, 3.32 cts. The pigs in lot 2 gained on an average 71.6 lbs., the cost of a pound of gain being 3.24 cts. when fed milk and grain. When fed sweet potatoes, over 100 lbs. were required per pound of gain, which would make the potatoes worth about \$1.60 per ton. In the author's opinion, sweet potatoes were not an economical feed, possibly because the pigs were too large. With the pigs in lot 6, which were somewhat younger than those in lot 2, they were found to have a value of \$2.40 per ton. On cowpeas, the pigs in lots 3, 4, and 6 gained on an average 6, 31, and 49 lbs. respectively. In the author's opinion, cowpeas are better adapted to young pigs than to older pigs. The composition of the artichokes fed is reported, but the results obtained are not spoken of at length.

The results of the individual tests are discussed in considerable detail. Some of the deductions follow:

“It would seem to be desirable to mix with hog rations some material as a substitute for grazing when feeding pigs in confinement, or if it is not possible to have a material

that will mix well with the grain ration, finely cut fodder or other vegetable material may serve equally well as a substitute. Finely cut or ground clover or pea-vine hay would possibly be a better coarse feed for pigs than the ground food [*i. e.* corn shives] used in these tests, as they contain more nitrogenous food matter and are also more easily digestible."

The dietetics of bread and butter, J. HEMMETER (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 4, pp. 207, 208).—An abstract of an article published in the Maryland Medical Journal. The digestibility of bread and butter in combination is discussed as well as other points.

Nutritious bread (*British Food Jour.*, 2 (1900), No. 15, pp. 68, 69).—A note on a special process of grinding grain and making bread which has been successfully employed in Paris.

The nutritive value of margarin as compared with that of butter, P. MOREAU (*Jour. Hyg.*, 25 (1900), No. 1218, p. 27).—A summary of the work of E. Bertarelli (*E. S. R.*, 11, p. 375).

What chemistry finds in feeds, F. H. HALL, W. H. JORDAN, and C. G. JENTER (*New York State Sta. Bul.* 166, popular ed., p. 6).—A popular bulletin on the composition and analysis of feeding stuffs (see p. 169).

How far can sugar be recommended as a feeding stuff, F. LEHMANN (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 1, pp. 17-22; 2, pp. 57-61; 3, pp. 88-90).—The author summarizes a number of feeding experiments which have been made with sugar.

Feeding animals on wheat, M. VACHER (*Rev. Sci. [Paris]*, 4, ser., 13 (1900), No. 3, pp. 93, 94).—A brief statement before the Société d'Agriculture on the value of wheat as food for animals, with discussion.

Advantages of compressing fodders, M. RINGELMANN (*Semaine Agr.*, 20 (1900), No. 974, pp. 14, 15).—The author discusses the advantages of pressing hay and straw, giving statistics regarding cost of transportation, etc.

A review of the methods of utilizing yeast as a nutritive material, L. MARCAS (*L'Ing. Agr. Gembloux*, 10 (1900), No. 6, pp. 429-438; *abs. in Belg. Hort. et Agr.*, 12 (1900), No. 4, p. 58).—The different methods proposed for utilizing waste yeast from breweries as a food for man and animals are reviewed.

Contribution to the study of the behavior of milk sugar in the body, especially in the intestines, E. WEINLAND (*Ztschr. Biol.*, 38 (1899), pp. 16-62).—Experiments are reported with young and old domestic animals and a newborn child. In some of the experiments the respiratory quotient is reported. From his investigations the author concludes that in the small intestine of newborn mammals, including man, lactase is present. The lactase was also found in the intestine of the adult dog, pig, and horse, but not in the small intestine of the adult steer, sheep, rabbit, or chicken. Other conclusions regarding the experiments are also drawn.

The value of milk protein for the formation of muscular tissue, W. CASPARI (*Ztschr. Diätet. u. Phys. Ther.*, 5 (1899), No. 5, pp. 393-412).—Experiments with dogs and man are reported, in which the balance of income and outgo of nitrogen was determined to learn the food value of plasmon, a prepared food made from casein.

Concerning plasmon (caseön) as a substitute for albumen, together with notes on the metabolism of protein, E. PLOCH (*Ztschr. Diätet. u. Phys. Ther.*, 3 (1899), No. 6, pp. 482-505).—The balance of income and outgo of nitrogen was determined in a number of cases.

Fat diet and stomach motility, H. STRAUS (*Ztschr. Diätet. u. Phys. Ther.*, 3 (1899), No. 3, pp. 198-210, fig. 1; 4, pp. 279-289, fig. 1).—Experiments in which the balance of income and outgo of nitrogen was determined. The conclusion was reached that giving large quantities of milk fat did not harm in any way the stomach motility.

The influence on metabolism and circulation of omitting water from the diet, W. STRAUB (*Ztschr. Biol.*, 38 (1899), No. 4, pp. 537-566).—Experiments with

dogs are reported, in which the balance of income and outgo of nitrogen was determined. In one case the carbon dioxide and water in the respired air were also determined. The principal conclusions follows: Omitting water from the diet increased the cleavage of protein in the body and had no effect on the cleavage of fat. When it does not produce pathological symptoms it is without effect on the blood pressure. The effect on protein of the withdrawal of water from the tissues is noticeable until the body regains its normal water content. Omitting water from the diet affects in a slight degree the amount of water excreted through the lungs and skin.

The physiological action of electric currents of high tension and great frequency, N. SPASSKI (*Physiologiste Russe*, 1 (1899), No. 15-20, pp. 235-241, pl. 1).—A form of apparatus for measuring and analyzing the respiratory products, devised in connection with the investigation, is described and experiments with guinea pigs reported.

The heat of combustion of meat of different animals, STUDENSKY (*Russ. Arch. Patol. Klin. i Bakt.*, 7 (1899), p. 305; *abs. in Physiologiste Russe*, 1 (1899), No. 15-20, pp. 303, 304).—Experiments showed that the heat of combustion of the flesh of horses, sheep, and foxes varied very little and was on an average 5,738 calories per gram ash-free flesh.

The determination of animal heat by direct calorimetric methods and by means of the metabolism of material, P. P. AVROROV (*Russk. Arch. Patol. Klin. i Bakt.*, 7 (1899), p. 207; *abs. in Physiologiste Russe*, 1 (1899), No. 15-20, pp. 301, 302).—A water calorimeter is described which measures directly the heat produced by an animal. Devices are also described for the measurement and analysis of the respiratory products.

Improvement of pasture as determined by the effects on the stock, W. SOMERVILLE (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 75-97).—A discussion of experiments abstracted from another source (*E. S. R.*, 12, p. 75).

Canadian experiments in animal growth and dairy products, W. BROWN (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 137-161, fig. 1).—A general discussion based on the experiments of the Canadian experiment stations in animal feeding and dairying.

Contributions to our knowledge of the physical properties of Swedish wool, G. SELLERGREN (*K. Landt. Akad. Handl. Tidskr.*, 38 (1899), Nos. 5-6, pp. 344-390, figs. 30).—The author gives a historical account of Swedish sheep raising, a description of the various breeds of sheep with reference to the quality of the wool, methods and apparatus used in wool examinations, and the results of the investigation. Sixty samples of wool were examined in all, according to crimp, fineness, length, elasticity, strength, color, and microscopic appearance. Among the breeds represented were Merinos, Cheviots, Southdowns, Dishleys, Oxfordshire Downs, and native sheep.

The value of succulent foods for swine, C. S. PLUMB (*Reprint from Breeders' Gaz.*, 1899, Dec. 20 and 27; 1900, Jan. 3, pp. 16).—The author summarizes briefly the results of a large number of experiments on the value of roots, etc., for swine.

The preparation of feed and the feeding of swine, J. KÄPPELI (*Jahresber. Landw. Schule Rütli*, 1898-99, pp. 61-67).—From a feeding and slaughter experiment with 2 lots of 3 pigs each, the conclusion was drawn that animals fed uncooked whole grain (barley and corn) in the first month of the test consumed less feed than those receiving meal ground from the same grains moistened with hot water. Pigs fed whole and raw grain increased much more rapidly until they were 9 months old than those fed soaked meal, while during the last six weeks of the test the increase was somewhat less.

Pig raising in Tunis, J. A. TOURNIÉROUX (*Bul. Dir. Agr. et Com.*, 5 (1900), No. 14, pp. 68-74, fig. 1).—Pigs and pig raising under local conditions in Tunis are discussed.

Zebra hybrids (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 385-388).—A brief summary of J. C. Ewart's experiments.

Poultry raising in connection with fruit culture, M. AAMOT (*Tidsskr. Norske Landbr.*, 7 (1900), No. 1, pp. 27-37).

Poultry at Geneva Experiment Station, S. F. HAXTON (*Reliable Poultry Jour.*, 7 (1900), No. 1, pp. 46-49, figs. 7).—A description of the station poultry house and of a number of experiments.

Oyster culture in France (*Sci. Amer. Sup.*, 49 (1900), No. 1258, p. 20169).—Quoted from the Journal of the Society of Arts.

Oyster culture in France, A. W. TOURGÉE (*U. S. Consular Rpts.*, 62 (1900), No. 233, pp. 182, 183).—Oyster raising and greening in France are described.

DAIRY FARMING—DAIRYING.

Effect of a number of oil cakes on the yield and composition of milk and the live weight of milch cows, C. MOSER and J. KÄPEL (*Jahresber. Landw. Schule Rütli*, 1898-99, pp. 48-60).—This experiment was made with 7 cows and covered 6 periods of about 15 days each. Two of the cows were regarded as checks and received a uniform ration throughout the experiment. The others received in different periods 2 kg. each of sesame cake, peanut cake, and linseed cake, and 1½ kg. of cotton-seed meal. The authors conclude that a beneficial effect was quite uniform with all of the oil cakes, the fluctuation in milk yield and live weight in different periods being greater than in the case of the control cows. While there was a small increase in live weight on sesame cake, linseed meal, and cotton-seed meal, there was an average loss of 5 kg. per cow on peanut cake. It is suggested that this may possibly have been due in part to a too narrow ration being fed during that period. With respect to the effect on the yield of milk the cotton-seed meal exceeded all others.

The authors believe that the experiment shows an undoubted superiority of cotton-seed meal over the other oil cakes in common use, and state that this conclusion is in accord with the experience of many extensive feeders in Germany.

Notes on sour milk, H. D. RICHMOND and J. B. P. HARRISON (*Analyst*, 25 (1900), May, pp. 116-124).—*Determination of the specific gravity of sour milk*.—The authors have employed a slight modification of Weibull's method (*E. S. R.*, 5, p. 644) of adding a known volume of ammonia and correcting the reading for the ammonia added. They tested the use of caustic soda in the place of ammonia, as suggested by De Koningh (*E. S. R.*, 11, p. 211). It was found in experiments with different acids that "although neutralization of an acid by soda always produces a loss of density, the figure varies not only with the acid, but also with the hydrogen atom neutralized by a polybasic acid. For this reason it is useless to apply any theoretical correction for milk. . . . With strong acids the change of density on neutralizing with ammonia is very much smaller than with soda, and in the opposite direction, and our results with milk indicate that it may practically be neglected."

The point at which milk may be considered sour and the rate of souring in the presence or absence of preservatives.—Stokes (E. S. R., 3, p. 195) states that milk which has not reached an acidity of 0.3 per cent of lactic acid (33.3°), or near it, will coagulate on boiling. The authors made a series of experiments, the results confirming almost absolutely the figures of Stokes. They found that milk tastes sour, on an average, when it has an acidity of 45° , although the variations are fairly wide. Fresh milk is stated to have an acidity of 20° ; when the acidity reaches 33° the milk curdles on boiling.

"It is quite certain that the 'acidity' of milk is not wholly due to lactic acid; indeed, the 'acidity' of fresh milk is due to the mono- and di-basic phosphates, and not to free acid at all. Seeing that 9.7 cc. $\frac{N}{10}$ lactic acid will curdle milk on boiling, while it requires a development of about 13° 'acidity,' it is highly probable that another acid very much weaker than lactic is produced, and we venture to think that carbonic acid is responsible for a portion of the acidity of sour milk; we know that carbonic acid is produced, and we have found that when milk is sufficiently sour to develop gas about half the acidity, as indicated by phenolphthalein, is shown to litmus (to which both milk and carbonic acid are approximately neutral).

"We have based a hypothesis on the facts that different acids do not give the same result, that salts of polybasic acids are present in milk, that both casein and albumin have acidic functions, and that the coagulation of milk at temperatures between 17 and 35° does not appreciably vary with the temperature; it appears to us that curdling of milk is due to an amount of acid being present to set up an equilibrium between the acids and bases present, such that certain acids, e. g., casein and albumin, are liberated. At a boiling temperature we are inclined to think that the curdling is determined by the coagulation of the albumin, the equilibrium being destroyed by the removal of one acid (albumin) from solution, and fresh amounts of albumin, and finally perhaps casein, are liberated.

"When milk tastes sour, it would appear that the equilibrium is such that a sour-tasting free acid exists in solution; while when milk curdles spontaneously the equilibrium is such that the insoluble acid casein is produced."

Experiments were made to determine the rate of souring of milk with and without the addition of preservatives (boric acid or formaldehyde).

"At high temperatures (say 80° hot summer weather) preservatives are comparatively useless unless added in relatively large quantities; the minimum quantities used by us, and also by Rideal, only increase the life of milk a few hours, and are equivalent only to a lowering of temperature of about 5° F. Unless milk can be made to keep at least 12 hours longer than without preservatives, we do not think much is gained by their use, and to do this in summer we think that the minimum amounts are 0.09 per cent boric preservative and 0.004 per cent formaldehyde.

"We would also draw attention to the increased rate of souring as time goes on, when preservatives are added. This indicates a possible danger in using preservatives in milk, as it seems far from improbable that succeeding generations of micro-organisms become in the presence of preservatives more active and more virulent, and if the use of preservatives were universal, there is a probability that they would cease to act. The work of Effront on yeast grown in the presence of sodium fluorid shows that this view is not a mere hypothesis."

Changes in the constants of butter fat as a result of feeding, A. RUFFIN (*Ann. Chim. Analyt. et Appl.*, 4 (1899), pp. 383-385; *abs. in Chem. Centbl.*, 1900, I, No. 1, p. 69).—The author discusses the investigation of Baumert and Falke (*E. S. R.*, 10, p. 685), in which he finds numerous analytical anomalies. He reports the following results from feeding experiments with different kinds of oil cakes:

Physical constants of butter on different feeding stuffs.

	Index of refraction.	Saponification number.	Volatile fatty acids.
Normal ration, hay, and alfalfa.....	30 -33	224 -232	27.6-34.9
Cotton-seed cake.....	28.5-30	222 -228	26.4-29
Cotton-seed cake and normal ration.....	29.5-30	221 -229	28.4-30
Peanut cake.....	30 -31	225 -228	26.9-29
Peanut cake and normal ration.....	28 -30	221.9-229	28 -32
Cocoanut cake.....	32 -33	231 -240	25.5-31

The author remarks that in practice the effects of the different feeding stuffs used largely neutralize each other, so that butter made from feeds which produce an abnormal product is rarely found on the market.

Butters from various countries compared, C. ESTCOURT (*Analyst*, 25 (1900), May, pp. 113-116).—The author has examined within the past year 250 samples of butter from different countries which were received direct from the importers. The water content was found as follows:

Water content of butter from different countries.

Origin of samples.	Number of samples.	Water content.		
		Average.	Highest.	Lowest.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Finnish.....	85	12.3	18.0	8.0
Danish.....	89	13.5	18.0	9.0
Irish.....	39	14.1	20.0	9.0
Swedish.....	14	13.75	17.8	11.8
Canadian.....	10	13.2	19.4	10.0
German.....	8	13.5	14.8	11.4

Only 9 of the Danish samples and 3 of the Finnish samples contained more than 15 per cent of water. Nearly all of the samples were examined for preservatives. None of the German or Swedish samples contained preservatives, and only one sample from Canada, one from Finland, and 3 from Denmark. The preservative in these cases was boric acid, which did not exceed 9 gr. per pound. All of the 37 samples of Irish butter examined contained boric acid in quantities varying from 5 to 46 gr. to the pound.

The volatile acids were determined by the Reichert process. Only 8 of the Finnish butters gave a Reichert figure of 16 or over, and 21 samples showed less than 13, 2 of these being 11.9. Only 4 of the Irish and Canadian butters were below 13. Of the Danish samples,

22 were above 16 and only 3 were below 13. The lowest samples of Swedish and German butter showed 13.7 and 13.5, respectively.

A study of the cause of mottled butter, C. F. DOANE (*Maryland Sta. Bul.* 64, pp. 43-54).—Experiments were conducted to test various theories as to the cause of mottled butter.

The butter from each of 5 churnings was divided into 2 lots, one of which was washed with water at 50° and the other with water at 35 to 40°. The washing occupied about 1 minute. A portion of each lot was worked 3 minutes and the remaining portion 4 minutes. Of the 5 lots washed with water at 50° and worked 3 minutes one was slightly mottled. Of the 5 lots washed with cold water and worked the same time 4 were mottled. The more frequent occurrence of mottled butter in the latter case is attributed to the less thorough working of the harder butter resulting from washing in ice water. None of the butter worked 4 minutes was mottled. In 4 additional experiments to determine the effect of using cold water the butter was allowed to remain in water at 40° for 15 minutes, after which one-half of each churning was worked 3 minutes and the other half 4 minutes. The butter worked 4 minutes was free from mottles in every case; that worked 3 minutes was slightly mottled in 2 of the tests. No material difference was observed between washing 1 minute and 15 minutes.

To determine the effect of the uneven distribution of salt the butter from each of 20 churnings was divided into 2 lots immediately after washing. One lot in each case was salted and the other left unsalted. Both lots were worked one minute and then set in the refrigerator. "Not one of the unsalted lots was at all mottled, while in every case the salted lots were very distinctly mottled." It was found by tasting that the light portions of the mottled butter contained very much less salt than the more deeply colored portions. The same difference was observed in a large number of samples of unevenly colored butter from commercial sources. The author therefore concludes that the uneven distribution of salt is the cause of mottles.

The effect of salt on the appearance of butter was further tested in 5 experiments, in each of which 2 lots of butter from the same churning were thoroughly worked and otherwise treated alike except that only 1 lot in each case was salted. The salted butter had a darker color than the unsalted butter, the difference being distinguishable immediately after working and very marked after 24 hours.

To determine if the more pronounced color of the salted butter was brought about by the action of salt in driving out more of the butter-milk, the content of casein in the samples of butter made in the experiments last noted was determined. In 3 churnings the salted butter had less casein than the unsalted butter, and in the other 2 comparisons the results were reversed. In each of 10 experiments 1 lot of butter was salted and worked without being washed and another lot

from the same churning was washed thoroughly to remove as much of the buttermilk as possible. In each case the butter was worked 1 minute. At the end of 24 hours all the lots were mottled alike. The results are considered as showing that a relative excess of casein is not the cause of the lighter color of unsalted butter as compared with salted butter, nor of the lighter portions of mottled butter.

Butter worked under different conditions sufficiently to secure an even distribution of the salt was scored by an expert as to grain. One churning was washed with water at 50° and another with water at 38 to 40°, both churnings being worked immediately after washing. Two other churnings were washed with water at 45°, one receiving 2 partial workings separated by an interval of 24 hours and the other being kept in a refrigerator 24 hours before being worked. The average score for grain in 3 repetitions of this experiment was highest for the butter washed with water at about 40° and worked immediately and lowest for the butter worked after 24 hours. Butter washed with water at 50° and worked immediately scored practically the same as that given 2 partial workings.

The effect of cold wash water on the solidity of the butter was also tested. The butter from each of 10 churnings was divided into 2 lots, 1 lot in each case being washed with water at 50 to 52°, and the other lot with water at 35 to 40°. Samples of the butter from both lots in each experiment were kept at 70° and also at 48° for 24 hours. All samples were then kept at 60° for 4 hours, when they were gradually heated to 80°. There was on the whole no practical difference in the 2 lots of samples as regards the time of becoming soft or the consistency of the butter at the end of the experiment.

Bacteria content of Finnish milk, O. v. HELLENS (*Nord. Mejeri Tidn.*, 14 (1899), Nos. 43-46, pp. 587-589, et seq.).—The milk supply of the city of Helsingfors was studied by the author from a bacteriological standpoint. Samples of market milk and that sold at retail stores were taken in the summer and in the winter. The samples taken during summer contained from 20,000 to 34,300,000 bacteria per cubic centimeter, the average being 4,745,000; while in the winter the bacteria content ranged from 70,000 to 18,630,000, and averaged 2,111,000. About 60 per cent of the summer samples contained over 1,000,000 bacteria per cubic centimeter against 35 per cent in the winter samples. The qualitative bacteriological examinations were restricted to pathogenic forms of bacteria, injections of new milk or cream and separator slime being made in guinea pigs. Of 34 samples, 24 were found to contain one or more forms of pathogenic bacteria. Seven different forms were identified, viz, *Bacillus tuberculosis*, *B. streptococcus pyogenes*, *B. staphylococcus pyogenes aureus*, *B. albus*, *B. citreus*, *B. bovis*, and *Bacterium coli commune*.

The examinations of the quantities of dirt in the milk showed that 35 samples out of a hundred contained less than 0.5 mg. per liter, and the average amount for 65 samples was 2.44 mg. The maximum content obtained was 10.6 mg. This favorable result is explained by the fact that on most Finnish dairy farms strict attention is paid to cleanliness in the stables and grooming the cows. The samples of milk examined were found to contain a very low percentage of fat; in the case of 100 samples only 68 came above 2.7 per cent. This is due to skimming or admixture of skim milk.—F. W. WOLL.

The invasion of the udder by bacteria, A. R. WARD (*New York Cornell Stu. Bul.* 178, pp. 260-280, pl. 1, figs. 2, dgm. 1).—The views of several investigators regarding the presence or absence of bacteria in the normal udder are noted, and investigations conducted by the author in continuation of earlier work (*E. S. R.*, 10, p. 1094) are reported.

Bacteriological examination was made of the udders of 19 cows, slaughtered on account of tuberculosis. None of the udders examined showed tubercular or other lesions. Plate cultures were made from the fore milk drawn just before the cows were killed and from glandular tissue of different portions of the udder, great care being taken to prevent contamination. Bacteria, for the most part micrococci, were found in nearly all cases, and summaries are given of the morphology, staining reactions, and cultural characteristics of the several kinds. The same kinds of bacteria were frequently found in the fore milk and in the glandular tissue. The germs isolated from the udders did not usually cause the souring of milk in cultures. Tables and diagrams show the sources of the different germs and their distribution in a number of the udders examined.

A study of the structure of the udder revealed no obstruction separating the milk cistern from that of the teat sufficient to prevent the invasion of bacteria.

"The free communication of the milk cistern with the more minute lactiferous ducts is at times interrupted by the sphincter muscles described by anatomists as present in those ducts. There is little ground, however, for considering them as serious barriers to the progress of micro-organisms $\frac{25}{1000}$ of an inch in diameter.

"That the milk ducts of the teat normally harbor bacteria is admitted by all. Some few, with whom the writer agrees, assert that the milk cistern normally harbors bacteria. Such being true, there is little reason to doubt that bacteria may find their way through the fine ramifications of the milk cistern (lactiferous ducts) to regions remote from the teat. Pathogenic organisms certainly do so when the udder is diseased, and to conceive that harmless ones do so in health is not difficult."

The author briefly discusses the practical bearing of the results of the investigation.

"Judged from the standpoint of the dairyman, who considers that souring is the one and only harmful change in milk, the contamination of milk from the interior of the udder, so far as has been shown in this work, might be disregarded as unimportant. Until more is known of the ordinary and of the occasional bacterial

inhabitants of the udder and of their ability to elaborate enzymes and toxic substances, the writer urges the recognition of that source of the contamination of milk."

Lessons from a milk record, R. SHANKS (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 99-112).—The author discusses the keeping of milk records, giving suggestions for weighing the milk, taking samples, and testing. The average yields of milk and fat of a herd of 25 to 30 cows for 5 years are given, together with notes on the system of feeding. Deductions are drawn from the record concerning the yield and quality of milk as affected by the age of the cows, abortion, character of food, and manner of milking. Young cows gave the richest milk and old cows the largest yield. Abortion lowered the yield of milk very decidedly and decreased the fat content over 0.2 per cent. Food is considered as having little or no permanent influence on the quality of the milk. The average results with 7 cows indicated that a good milker obtained a higher percentage of fat in the milk than a poor milker. Notes are given on the selection of a profitable cow.

Winter feeding for dairy cows, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 8* (1899), pp. 95, 96).—A brief note on the rations fed dairy cows at Newton Rigg Penrith.

The college herd, C. W. BURKETT (*New Hampshire Sta. Bul. 68*, p. 156).—A tabulated summary of the herd record from November 1, 1898, to October 31, 1899.

"The herd has been equivalent to 323 milch cows and 65 dry cows for one month, and has produced 166,728 lbs. of milk and 8,864.57 lbs. of butter, making an average monthly yield per head for 388 cows, 429 lbs. of milk and 22.8 lbs. of butter, or 5,148 lbs. of milk and 273.6 lbs. of butter for the year."

On the influence of the milking on the production of the cows and the quality of the butter, K. N. KRISTENSEN (*Norsk Landmandsblad*, 18 (1899), No. 44, pp. 536-539).

The milk supply of large cities, BOYSEN (*Milch Ztg.*, 29 (1900), No. 6, pp. 81-83).—A discussion of the milk supply of Copenhagen based on observations made by the author.

Experiments in the purification of milk, DUNBAR and I. KISTER (*Milch Ztg.*, 28 (1899), Nos. 48, pp. 753-756, figs. 3; 49, pp. 771-773; 50, pp. 787-789).—Comparative tests of a centrifuge and a Danish sand filter with especial reference to the removal of dirt and bacteria and changes in the character of the milk are reported in detail.

Preservation of milk samples for the purpose of investigation, H. SCHROTT (*Milch Ztg.*, 29 (1900), No. 12, p. 180).—The method of pasteurization practiced by the author in preserving a series of samples of milk for a composite test is described. The milk was kept at a temperature of 70 to 82° C. for 1 to 2 hours. Each day an equal portion was added to the first sample and the pasteurization repeated. Composite samples covering 14 days were secured without difficulty in this way.

Sampling milk and cream (*Vermont Sta. Spec. Bul.*, Oct., 1899, pp. 4).—Detailed directions are given for taking samples of milk to test individual cows and the entire dairy as a whole, to test cream and skim milk from the dairy, to test buttermilk or whey, and to check correctness of test at creamery or cheese factory.

A modification of the Babcock milk test, M. SIEGFELD (*Dairy World*, 20 (1900), No. 6, p. 15).—The milk and sulphuric acid are mixed as usual and 2 cc. of amyl

alcohol and a sufficient quantity of hot diluted sulphuric acid (temperature 90–100° C. and sp. gr. 1.5) to fill the test bottle to the upper part of the graduated neck are added. The samples are whirled 3 minutes and the reading taken. Only one whirling is required. Determinations made by this method agreed closely with those made by the Gerber test and the Adams gravimetric method.

The relation between specific gravity, fat, and solids-not-fat in milk, N. LEONARD (*Analyst*, 25 (1900), Mar., pp. 67–69).—The author worked out the average error in the calculation according to a formula, and found that the error varied with the season.

On the payment for milk according to the content of solids, H. SCHROTT (*Milch Ztg.*, 29 (1900), No. 5, pp. 68–71).—This subject is discussed at some length.

Bitter milk for infants, UHL and O. HENZOLD (*Milch Ztg.*, 29 (1900), No. 5, pp. 65, 66, fig. 1).—The cause of a bitter taste in samples of prepared milk from 2 factories was traced to a species of *Clostridium* present in the milk sugar which was added in the process of manufacture. The bacterium is illustrated and described. It was not found in a sample of milk sugar containing no albuminous substances.

VETERINARY SCIENCE AND PRACTICE.

Immunization against Texas fever by blood inoculation, W. H. DALRYMPLE, W. R. DODSON, and H. A. MORGAN (*Louisiana Stas. Bul.*, 57, 2. ser., pp. 143–185, figs. 6).—In experiments in blood inoculation, 9 susceptible heifers were divided into 3 groups and each group was inoculated with the blood of a different animal. The animals from which blood was taken for inoculation were an immunized steer from north of the quarantine line, a native animal, and a Jersey calf born on the college grounds. Five cubic centimeters of blood from these animals was inoculated into each of the 9 animals to be immunized. The blood from the Jersey calf produced fever in the 3 heifers into which it was inoculated and caused a decrease in the number of blood corpuscles. The 3 heifers were afterwards exposed to natural infestation with ticks without developing acute cases of Texas fever. The other 2 animals from which blood was taken for inoculation were believed to have recovered from more severe attacks of Texas fever and to possess, therefore, blood of greater immunizing power. The 3 heifers which were inoculated with blood from the native animal developed high temperatures and showed a decrease in the number of blood corpuscles, as usual under such conditions. During the inoculation fever, one of the animals was attacked by 2 healthy animals and died as a result. Similar results were obtained from the blood of the immune Northern steer. It was observed, however, that the blood of this steer was less virulent than that of the native steer, but that its immunizing properties were fully as satisfactory. Two Herefords

were each inoculated with $2\frac{1}{2}$ cc. of blood from a recently immunized animal, with entirely satisfactory results. Mr. J. T. Bryant successfully immunized 2 Hereford yearlings (imported from Iowa) by inoculation with 2 cc. of blood from a native yearling.

The authors give a description of the method to be used in securing the blood for inoculation and in making the inoculation in animals to be immunized. Experiments were conducted for the purpose of determining whether the blood in ticks could be used for inoculation purposes. Ticks were collected and carefully washed in a solution of corrosive sublimate and sterilized water. The blood from these ticks was then used in inoculating 4 animals. The first animal (a grade Shorthorn) was inoculated with blood obtained from 3 large cattle ticks which had been removed from native cattle. The temperature of this animal showed an elevation one week after the injection, then returned to the normal, and became high again 15 days after the injection. The highest recorded temperature was 104.6° and the blood corpuscles were diminished by about one-third. The animal was placed on a tick-infested pasture in the following spring without showing any evidence of fever. The second animal (a grade Shorthorn) was inoculated on August 29. Its temperature was quite high during the 2 following days, but returned to the normal on the fourth day. Since it seemed doubtful whether the animal had really become immune, a further inoculation was made with blood taken from ticks which had been maintained for 7 hours at a temperature of -12° C. After this second inoculation, the number of blood corpuscles diminished, but there was no temperature reaction except for one day. Later, a single tick was found on the animal, so that this case was considered too complicated for drawing definite conclusions. The third animal was a common 2-year-old steer which was inoculated with blood from ticks which had been kept for 7 hours at a temperature ranging from -10 to -12° C. The animal developed no symptoms of Texas fever for 18 days after the inoculation, and was then inoculated with blood from a native cow. One week later a good case of inoculation fever developed. It appears from this experiment that the organism of Texas fever may be destroyed or attenuated while in the body of the ticks, and this may be the explanation of the fact that tick infestation in late fall or early spring produces a milder form of the disease than that of midsummer. The fourth case was a heifer which was inoculated with the blood from ticks and developed a high fever on the nineteenth day after inoculation, the blood corpuscles being also reduced by about 50 per cent. Recovery then began to take place, but the animal became deeply mired during this time and died.

An experiment was tried in the preservation of blood for inoculation purposes. One-tenth per cent of potassium oxalate was added to blood and this blood was then sent to Ann Arbor and tried at home

after 4 days' preservation, with negative results in both cases. No bacterial growth had taken place in the blood, but the organism of Texas fever was destroyed. A cross Hereford and Shorthorn bull, 2 years of age, was imported from Missouri and inoculated in the ordinary way, but died on the third day after inoculation. It was supposed that in this case death resulted from septicæmia.

The general results of these experiments may be summarized as follows: Blood from recently immunized animals gave a milder and less protracted form of inoculation fever than a similar amount of blood from a native animal. If animals were allowed a sufficient time to recover completely from the inoculation fever, they did not suffer when exposed to tick infestation. The experiments indicate that it is possible to take engorged ticks from recently immunized animals and ship them to considerable distances, thus using them as receptacles for containing the virulent blood. It appears also that although the inoculation fever which results from the use of such blood is mild, the immunity produced is complete.

Studies on cattle plague, M. NENCKI ET AL. (*Arch. Sci. Biol.* [*St. Petersburg*], 7 (1899), No. 4, pp. 303-336).—The authors' researches upon cattle plague were begun in the province of Kouban in 1895. It was soon discovered that the blood of animals which had recovered from this disease contained a substance which confers immunity on other animals. Considerable progress has been made in perfecting means for the preparation of the antitoxin and in taking blood from experimental animals. The animals which are to be immunized receive a dose of 0.2 cc. of virulent blood. After about 2 days, when it appears that the disease has invaded the organism, the animal receives a dose of therapeutic serum. Immunization has been accomplished by the authors by 2 methods, which they have called rapid and slow, respectively.

The benefits derived from immunization are stated by the authors as follows: The danger of contagion from the excrement of the animals is avoided and abortion in pregnant cows prevented. The injection of immunizing serum has no influence upon the secretion of milk. Animals which are susceptible to cattle plague may be immunized in 3 ways, by the serum alone, by the serum and virulent blood, and by inoculating the animal with virulent blood and then giving an injection of serum after the disease has shown its first symptoms, which occurs usually in from 1 to 3 days.

In experiments which were conducted to determine the value of bile in the production of immunity, the authors came to the following conclusions: The green bile of animals killed by severing the jugular vein from 5 to 7 days after the beginning of the fever is most effective in producing immunity. The bile of animals which have died of cattle plague is yellowish in color and is not suitable for use in preventive

inoculation. Immunization by means of bile is a method which in general is too uncertain in its results to be recommended.

Results of recent investigations on foot-and-mouth disease and their practical application, C. EBERTZ (*Arch. Wiss. u. Prakt. Thierh.*, 26 (1900), No. 2-3, pp. 155-204).—The author presents an elaborate critical review of the literature of this subject. A commission which was appointed for investigating vaccination methods against this disease did not carefully determine the virulence of the lymph which was used for this purpose, its value, nor the varying susceptibility of the animals which were to be inoculated.

The author considers in a critical manner the results obtained from the application of Löfler's seraphthim method and Hecker's inoculation experiments against foot-and-mouth disease. The author believes that the reports which have hitherto been made on the value of various methods in controlling this disease are to some extent vitiated by the failure to make allowance for the large number of exceedingly mild cases which are nearly always to be observed in extensive outbreaks of the disease. The author states that numerous experiments carried out under government control according to Hecker's inoculation method show that in its present form it is not adapted to the production of such results as have been claimed for it.

Sheep scab, A. W. BITTING (*Indiana Sta. Bul.* 80, pp. 63-76, figs. 8).—The author gives a general account of the nature of this disease and a description of the parasitic mite which causes the disease. Brief notes are presented on the dips to be used for the destruction of the scab mite and on the methods of applying such dips, together with a description of dipping tanks. The State statistician secured reports from sheep owners which indicate that sheep scab existed in 320 localities in the State and that 9,338 sheep were affected. Further inquiry developed the fact that some other conditions which caused roughness in the fleece had been mistaken for scab.

The bulletin contains a copy of the live-stock law of Indiana affecting the spread of sheep scab and the regulations of this Department concerning the dipping of sheep which are affected with scab.

Scab in sheep—suggestions for its eradication, WALLACE (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 117-137).—The author gives statistics compiled from circulars of inquiry which show that the most serious outbreaks of sheep scab occur during the winter months. A brief outline of the life history of the scab mite is presented. On the subject of dipping, the author gives a general discussion of the peculiar local conditions which must be considered in this operation throughout Scotland and Wales. In the mountainous regions of Wales about 45,000 sheep belonging to 300 owners are grazed. These sheep are in herds of from 5 or 6 up to 2,000. These

regions are not isolated by division fences into separate areas, and it is therefore necessary that dipping should be regulated by some central authority.

Among the dipping materials considered by this author, the following may be mentioned: A white arsenic dip made by boiling 45 lbs. of arsenic and 45 lbs. of carbonate of soda crystals in $2\frac{1}{2}$ gal. of water. This to be dissolved in water at the rate of 2 lbs. to 100 gal. Sulphur in the insoluble form of flowers of sulphur is recommended as an effective dip. In order that sulphur may be more evenly distributed in the dip, it is recommended that an equal weight of soft soap be added. Tobacco is recommended in a dip made as follows: 100 lbs. of dry leaf-tobacco, 10 lbs. of blue vitriol, 15 lbs. of common salt, and 2 lbs. of oil of turpentine. Carbolic acid has also been found effective in killing living parasites, but it is dangerous if used in a strength sufficient to kill the eggs. Pitch oil is not recommended on account of the injurious effects which it has upon the wool.

The author makes the following recommendations regarding dipping: The dipping season should be from the first of June to the middle of November. Counties should be subdivided into areas in which all sheep may be dipped within a period of 15 days, a second dipping to take place between the fifth and fourteenth day after the first dipping. Inspectors should be appointed by the Board of Agriculture and no sheep should be removed from one area to another during the dipping season without being dipped immediately before removal. All railway trucks and pens in public markets should be thoroughly disinfected. Dipping tanks should be provided, the total cost being met by the sheep owners. Late autumn dipping is more generally practiced than spring dipping and is most effective. It is especially desirable also from the fact that *Melophagus ovinus* is killed along with the scab mite. Spring dipping is desirable where the fall dipping has not proved successful, and is usually more or less effective in destroying the grass ticks of the genus *Ixodes*, and thereby preventing louping-ill.

Swine plague, P. FISCHER and A. T. KINSLEY (*Kansas Sta. Bul.* 91, pp. 18).—The veterinary department of the station is conducting experiments in protective inoculation against swine plague. Attenuated cultures of *Bacillus suis* were used as prepared by H. J. Detmers.

A college herd of 434 pigs had been bought from different localities and was divided into 2 lots containing 114 and 320 respectively. Lot 1 was inoculated July 11, 1899. Lot 2 was inoculated August 11 of the same year. On July 24, or 13 days after the inoculation of lot 1, the pigs began to die of swine plague and continued to die until October 8, when only 7 pigs remained out of the 114. On August 19, or 8

days after the inoculation of lot 2, the pigs of this lot began to die, and at the end of 45 days only 56 were left of the 320.

In order to determine whether the inoculation with Detmers' virus was the cause of the outbreak of the disease, 10 average pigs were selected from lot 2 for special experiment. The temperatures of these pigs were taken and were found to range from 104.4 to 109° F. Only one of the pigs had a normal temperature. Each of these 10 pigs received 5 cc. (10 full doses) of a cheek culture of *Bacillus suis*. In some of them a slight rise in temperature was noticed on the second day, as a possible effect of the lymph. In others no effect whatever was noticed. The pig which had the normal temperature at the beginning of the experiment was the only one which survived. The authors believe that all those which died were infected with swine plague before the beginning of the experiment. The observation of temperature of pigs seems to be a valuable method of diagnosing swine plague before other symptoms are manifested.

The regular dose of the virus is from 0.1 to 1 cc., but the authors found by experiment that pigs could receive 25 times this amount without permanent bad effects. It was concluded, therefore, that protective inoculation when carefully performed can not cause an outbreak of swine plague. Notes are given on an outbreak of swine plague in a herd of a farmer, from which it is apparent that pigs may be infected with swine plague for a period of 33 days before deaths begin to occur.

Nine hundred and fifty-five pigs belonging to farmers in the State have been inoculated with the Detmers virus and not one of this number has died of swine plague, although many of them have been exposed. The authors believe that the method can be so perfected as to be of considerable practical value but do not recommend its general adoption until further experiments have been conducted.

New investigations on *Trichophyton minimum*, LE CALVÉ and H. MALHERBE (*Arch. Parasit.*, 2 (1899), No. 4, pp. 489-503, fig. 1).—The authors give a detailed description of the dermatomycosis produced by this organism. From a study of the circumstances under which outbreaks of the disease were observed it is concluded that the fungus lives during the winter in a vegetative condition in the soil or filth of stables.

The mycelium of this organism secretes about itself a sort of substance of a mucoid nature. Some experiments were conducted to determine the chemical nature of this substance. Boiling water, dilute mineral acids, dilute bases, and dilute organic acids had no effect at all upon the mucoid matter, except in the case of acetic and hydrochloric acids, which seemed to clarify the substance. Numerous other tests were made, with the result that the substance is believed to be of a

proteid nature. The organism not only produces a disease of the skin and hair in the horse, but may be transmitted to dogs and guinea pigs. It was not observed on man and no experiments were conducted to determine the possibility of transmitting it to man.

T. minimum has a delicate, branched mycelium, with very small spores. The vegetative portions are inclosed by an external secretion of a proteid substance, which constitutes a source of reserve nutriment for the fungus. The culture media which are best adapted for growing this organism are such as contain albuminoid substances. The organism is believed to live in 2 conditions—as a parasite in the skin of the horse and dog, and in a vegetative condition during cold weather in the soil or in filth.

Notes on the mortality of incubator chicks, G. W. FIELD ET AL. (*Rhode Island Sta. Bul.* 61, pp. 49-60).—One of the most serious sources of loss in poultry raising is the death of incubator chicks, and the experiment station undertook an investigation to determine the proportion of chicks that died and the causes of death.

In the summer of 1899, 826 dead chickens from incubators were examined. Fewer males died than females, the proportion being 387 to 439. *Post-mortem* examinations indicated that the diseases of incubator chickens may be classified under 4 heads: Diseases due to heredity or environment, to mechanical causes, to imperfect sanitation, and to improperly balanced ration.

Alternate periods of heat and cold during incubation bring about a considerable percentage of abnormalities, 33 per cent of the chickens examined indicating a trouble of this origin. Diseases due to heredity may be the result of congenital weakness resulting in special susceptibility to sickness or in malformations. Tuberculosis among chickens was in several cases contracted after hatching through the infected brooder. Another sort of constitutional weakness is a failure to absorb the yolk at the proper time. Poultry raisers frequently complain of "bowel trouble" as an important cause of death among incubator chickens, and this trouble was found to be caused by the nonabsorption of the yolk, which happened in a large proportion of the chicks which died before hatching, and in 13.3 per cent of the hatched chicks abnormalities of the yolk sac were noticed.

Many deaths occurred from overcrowding or trampling and suffocation in the brooders. The fatalities due to imperfect sanitation are more important. Tuberculosis, according to the observations of the authors, was found in 15.1 per cent of the dead chicks, tubercles being found in the lungs of 113 cases, on the walls of the heart in 5 cases, on the walls of the gizzard in 5 cases, and on the intestine in 1 case. It was found that removing the "hovers" and setting them out of doors in full sunlight reduced the presence of tuberculosis to a considerable extent. The lungs were found to be congested in 243 cases or 29.4 per cent. The greatest number of deaths resulted from improper feed-

ing, 75.6 per cent manifesting abnormality in the gall bladder. In such cases the green gall stains the adjacent organs, or even the abdominal wall, and a green area is to be seen on the outside of the abdomen, close to the posterior edge of the breast bone.

Experiments were conducted to determine the hygienic effects of different rations, 219 chicks being placed in 4 pens under similar conditions. All pens were fed as much as they would eat for 30 days. One pen was fed a diet of equal parts of egg, liver, and grain, boiled together and chopped fine, with an addition of sliced onion, oat sprouts, etc. The mortality was 3.9 per cent. The second pen was fed on grain and green stuff, all animal proteid being omitted. The mortality was 9.5 per cent. The third pen was fed on grain alone, with a resulting mortality of 32.7 per cent. The fourth pen was fed on egg, liver, and green stuff, all grain being omitted. The mortality was 63.7 per cent.

The general conclusions of the bulletin may be stated as follows: Careful examination of dead chicks will usually disclose the cause of death. Death from overcrowding can be easily corrected. In order to reduce the amount of tuberculosis, the brooder should be given as much sunlight and air as possible. Disorders of the liver and gall bladder may be recognized from the green stain. In order to prevent this, more animal food should be given. Diarrhea is frequently the result of feeding a too large proportion of animal food.

The dangers of water drinking, W. O. WILLIAMS (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 112-117).—The source of some of the principal dangers to live stock in contaminated water is pointed out and the importance of clean water insisted upon.

The micro-organisms in tumors, N. SJÖBRING (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 4, pp. 129-140, figs. 4).—The author made a study of 30 kinds of tumors, including carcinomata, sarcomata, and myomata. A number of experiments were conducted in transplanting these tumors from man to animals. The author concludes that the organisms which are concerned in the production of tumors have heretofore been improperly classified and belong to the Rhizopods.

On infections produced by coli bacilli, E. ZSCHOKKE (*Schweiz. Arch. Tierh.*, 42 (1900), No. 1, pp. 20-29).—The author reviews the literature upon this group of bacilli and relates the evidence which he collected from personal observations to indicate that polyarthritis of calves and croupous enteritis of cats is due to the pathogenic action of organisms belonging to this group.

Combating tuberculosis in domestic animals, B. BANG (*Mannedsskr. Dyrlæger*, 11 (1900), No. 10, pp. 355-388).—An elaborate discussion of the literature of the problem, with a critical account of the various methods which have been adopted in different countries.

Treatment of anthrax with creolin, YORDAL (*Berlin. Tierärztl. Wechschr.*, 1900, No. 6, pp. 63, 64).—The disease was not checked by doses of 25 gm. creolin.

Anthrax in the dog, H. MARTEL (*Ann. Inst. Pasteur*, 14 (1900), No. 1, pp. 13-25).—Phlorizine and pyrogallol diminished the natural resisting power of the dog to anthrax. The rabid dog is very susceptible to anthrax. Anthrax bacilli by frequent passing through dogs become more virulent and undergo morphological changes, becoming shorter and thicker.

Contribution to the study of Texas fever, T. CARRASQUILLA (*Bol. Soc. Agr. Mexicana*, 24 (1900), No. 5, pp. 89-94).—An account of the symptoms, pathological anatomy, treatment, and prophylaxis by serum inoculations.

Texas fever, M. FRANCIS and J. W. CONNAWAY (*Texas Sta. Bul.* 53, pp. 53-106, figs. 13).—This is a report upon the cooperative work of the Texas and Missouri experiment stations and the Missouri State Board of Agriculture, published also as Missouri Station Bulletin 48 (E. S. R., 11, p. 988).

Experimental inoculation against foot-and-mouth disease according to Hecker's method (*Deut. Thierärztl. Wchenschr.*, 8 (1900), No. 3, pp. 11-23).—Extensive experiments with this method indicate that it is ineffective in protecting animals against the disease and in influencing the course of the disease.

Combating foot-and-mouth disease, SCHUTZ (*Deut. Landw. Presse*, 27 (1900), No. 7, pp. 63, 64).—A general discussion of the symptoms of this disease, with recommendations of preventive measures.

Bacteriological conditions in mastitis of cows, C. O. JENSEN (*Maanedsskr. Dyrleger*, 11 (1900), No. 10, pp. 337-354).—The forms of mastitis are classified in 3 groups—lymphogenic, hæmatogenic, and galactogenic. The bacteria which are most often found in connection with mastitis are Streptococci, Staphylococci, and Coli bacilli.

Omphalo-phlebitis of calves, BITARD and P. LEBLANC (*Jour. Med. Vet. et Zootech.*, 5. ser., 4 (1900), pp. 10-12, fig. 1).—A discussion of the etiology and symptoms of this disease is given, together with various treatments which are recommended. The treatment should be preventive, and consists for the most part in a careful antiseptic treatment of the umbilical cord.

Dehorning (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 1, pp. 10-12).—A table is given showing the amount of milk and butter fat before and after dehorning. Only a slight decrease was noted.

Determining the age of slaughtered cattle, BUNGE (*Deut. Landw. Presse*, 26 (1899), No. 94, p. 1062).—Quoted from the *Deutsche Thierärztliche Wochenschrift*. The author bases his determinations of the age of cattle on changes in the spinal process.

Protective inoculation against hog cholera, H. JOST (*Berlin. Tierärztl. Wchenschr.* (1900), No. 4, pp. 37-39).—A discussion of the methods to be adopted in making the inoculation.

Manifestations of disease in horses which are kept in badly ventilated stalls, SEEGER (*Ztschr. Veterinärk.*, 12 (1900), No. 2, pp. 65-68).—In badly ventilated stalls horses manifest not only a generally unsatisfactory condition, but show a special tendency toward congestion of the brain and catarrh of the respiratory organs.

The horse's foot and how to shoe it, DEWAR (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 239-294, figs. 32).—This article contains detailed directions for the preparation of the hoof and the shaping of the shoe, with reference to special purposes or the correction of defects in the foot or gait.

Rabies and its prevention, LOIR (*Bul. Dir. Agr. et Com.*, 5 (1900), No. 14, pp. 74-78).—A general discussion.

Caponizing cockerels (*Queensland Agr. Jour.*, 6 (1900), No. 1, pp. 25-27, figs. 4).—A description of the operation and of the necessary instruments.

Bacillol, Protargol, and Tannoform, C. AUGERSTEIN (*Berlin. Tierärztl. Wchenschr.*, 1900, No. 6, pp. 61, 62).—This article reports results which were obtained in antiseptic treatment. Bacillol in a 2 per cent solution gave excellent results. Protargol is expensive, but is so effective even in weak solutions that its cost is no great disadvantage. The author believes that tannoform is a better remedy than iodoform in cases where the latter would be used.

TECHNOLOGY.

Chloroform in wine making, L. E. MOLINE (*Reprint from L'Agriculture Moderne in Bol. Soc. Agr. Mexicana*, 25 (1900), No. 12, pp. 236, 237).—This article gives the method of controlling fermentation in wine making by the use of chloroform. For this purpose the chloroform is incorporated with 5 times its volume of alcohol and added to the must in the proportion of 4 or 5 cc. per liter. After some days, when the must is sufficiently colored, the wine is decanted and the pomace pressed as usual. The wine may then be pasteurized at 80° C., when the excess of alcohol and chloroform will pass off. It is claimed that this method is uniform in its action and leaves no undesirable odor or product behind, as in the use of sulphuric acid. Even if the chloroform should remain, it would produce no undesirable results. This method was found especially valuable in the treatment of champagne, as the product was of better quality and the time of maturing shortened at least one year.

On a new process for extracting sugar from low products, P. LECOMTE (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 20, pp. 1336, 1337).

Ozone for the purification of sugar-beet juices (*Sugar*, 11 (1899), No. 12, pp. 182, 183).—Notes on the use of electrically prepared ozone in improved methods of beet-sugar manufacture.

Verley's method of treating sirup with ozone (*Ind. Electrochim.*, 3 (1899), pp. 25-29; *abs. in Sci. Abs.*, 2 (1899), No. 21, p. 630).

Practical data for the use of sulphurous acid in beet-sugar extraction (*Sugar Beet*, 21 (1900), No. 1, pp. 2-4).

Russian electrical methods for beet juice and sirup epuration (*Sugar Beet*, 21 (1900), No. 1, p. 9).

Abnormally high polarization of some mill juices, H. C. PRINSEN-GEERLIGS (*Meded. Proefstat. Suikerriet West Java*, No. 39, pp. 19).

Annual report of the enological station of Haro, Spain, VICTOR C. MANO DE ZÚÑIGA (*Memoria Anual Estación Enológica de Haro*, July, 1899, pp. 35, map 1).—This gives an account of the work at this station during 1899 in the following lines: Correspondence, field, and laboratory investigations on grape growing and wine making, and meteorological observations.

The manufacture of white wine from red grapes, A. BOUFFARD and L. SÉMICHOX (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 155-170, fig. 1).

New process of wine making (*Sci. Amer.*, 82 (1900), No. 6, p. 92).—Methods tested in France and Tunis by which the grapes are subjected to heat and pressure instead of using them cold and allowing the juice to exude naturally. The result is claimed to be more juice, better color and "body."

Investigations on wine ferments and the use of pure cultures in wine making, V. PÉGLION (*Staz. Sper. Agr. Ital.*, 31 (1898), No. 12, pp. 81-110, pls. 2).

The use of selected yeasts in wine making, E. KAYSER (*Ann. Sci. Agron.*, 1899, II, No. 1, pp. 130-158).

Yeasts in viticulture, M. E. POZZI-ESCOT (*Jour. Agr. Prat.*, 1900, I, No. 6, pp. 212-217).

The sterilization of grape juice the solution of wine making in hot climates, C. MAYER (*Agr. Jour. Cape Good Hope*, 15 (1899), No. 10, pp. 651-653).

Wine making in Oran, G. LOEVI (*La vinification en Oranie*. Paris: G. Masson, 1899, pp. 300, ill.).—This work treats of the methods employed in making wine in the Province of Oran, Algeria.

Wine making in Russia: IV, Northern Caucasus, M. BALLAS (*St. Petersburg: Department of Agriculture, 1898, pp. XII + 256; rev. in Selsk. Khoz. i Lysov., 192 (1899), March, pp. 701, 702*).—The total area of vineyards in the whole Caucasus is 291,000 acres, from which there are annually obtained 7,610,000 bucketfuls of wine and more than 230,000,000 lbs. of grapes. The annual export of Caucasian wine amounts to about 20,000,000 lbs.—P. FIREMAN.

Wine making in warm countries—Algeria and Tunis, J. DUGAST (*Vinification dans les pays chauds—Algérie et Tunisie*. Paris: G. Carré & C. Naud, 1900, pp. 281+48, figs. 58).

Report on the salted wines of Tunis, A. GIRARD and M. FLEURENT (*Bul. Min. Agr. [France], 18 (1899), No. 6, pp. 1157-1161*).—A number of analyses of samples of wine, including proximate and ash constituents, are reported.

Cider, X. ROCQUES (*Le cidre*. Paris: Masson et Cie, 1899, pp. 171, figs. 22).—This is a volume of *Encyclopédie scientifique des aide-mémoire*.

Cider making in Devonshire, E. A. S. (*Agr. Students' Gaz., n. ser., 9 (1900), No. 6, pp. 168-173*).—This is a brief description of the machinery and methods employed.

Cider making, O. CUISSET (*Jour. Agr. et Hort., 3 (1899), No. 8, pp. 153-155*).

Investigations into the manufacture of cider, F. J. LLOYD (*Bd. Agr. [London], Rpt. Agr. Ed. and Research, Great Britain, 1898-99, pp. 158-161*).—These investigations have extended over a number of years. The present article deals with composition of the fresh juice, manipulation of cider, fermentation, filtering, and preservatives for checking fermentation.

The manufacture and consumption of cider in Paris during 24 years (*Rev. Sci. [Paris], 4. ser., 12 (1899), No. 15, p. 479*).

Tests of the freezing of cider, DESCOURS-DESACRES (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 1, pp. 51, 52*).

Norwegian barley for malting purposes, F. H. WERENSKIOLD (*Tidsskr. Norske Landbr., 7 (1900), No. 1, pp. 20-26*).

The preparation of casein for use in the industries, C. BESANA (*Staz. Sper. Agr. Ital., 32 (1899), No. 6, pp. 628-633*).

Apparatus for steaming and drying the cocoons of silkworms, E. VERNON (*Ann. R. Staz. Bacol. Padova, 27 (1899), pp. 97-104*).

AGRICULTURAL ENGINEERING.

Broad and narrow tires, C. M. CONNER (*South Carolina Sta. Bul. 48, pp. 16*).—An account is given of two tests (August 17 and October 3, 1899) on wet and dry sandy roads of the draft, as measured with the dynamometer, of wagons with metal wheels of standard height having tires 6 in. and 1½ in. wide. The load in each case was 2,000 lbs., the length of run 200 ft. The results were as follows:

"In all conditions of sand roads the draft of the broad tire was from 7.49 to 28.6 per cent less than that of the narrow tire.

"There was little difference in the draft of the broad tire on wet or dry sand. The narrow tire pulls a little more than 5 per cent lighter in wet sand.

"The condition of the road was not improved by the use of the broad tire except for broad tires.

"The draft of the narrow tire was 5.73 per cent less in loose sand than in a well-formed rut of the broad tire."

The results of tests of a similar character at other stations are briefly summarized.

Report of the engineer, O. V. P. STOUT (*Rpt. Nebraska State Bd. Agr. 1898*, pp. 211-231).—A record of the rates of discharge of the principal streams of Nebraska. A previous report is noted in E. S. R., 9, p. 798.

Note on the prospects of the Nile summer water supply in 1900, W. E. GARSTIN (*Millers' Gaz.*, 23 (1900), No. 44, p. 544).—The discharge of the river in years of low supply (1878 and 1889) is compared with its present condition, and means of meeting the prospective low supply are suggested.

Irrigation in the Belgian Campine, M. BEAU (*Jour. Agr. Prat.*, 1899, II, No. 42, pp. 558-561).

A gaging apparatus for testing pumps, P. FERROUILLAT (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 1-4, fig. 1).

Trial of oil engines, R. STANFIELD ET AL. (*Trans. Highland and Agr. Soc. Scotland*, 5. ser., 12 (1900), pp. 388-408, figs. 14).—Descriptions and tests of ten machines are reported.

The future of the petroleum motor, J. GOBIET (*L'Ing. Agr.*, 10 (1900), No. 8, pp. 515-527).

Compend of mechanical refrigeration, J. E. SIEBEL (*Chicago: H. S. Rich & Co.*, 1899, 3. ed., pp. XI+420).—This is stated to be "a comprehensive digest of applied energetics and thermodynamics for the practical use of ice manufacturers, cold-storage men, contractors, engineers, brewers, packers, and others interested in the application of refrigeration." The book discusses in detail the principles of refrigeration and their practical application in ice making and storing; cold storage; refrigeration of packing houses, breweries, etc. An appendix gives the literature of the subject.

STATISTICS—MISCELLANEOUS.

Twelfth Annual Report of Kansas Station, 1899 (*Kansas Sta. Rpt. 1899*, pp. XX).—This includes the organization list of the station, reports of the treasurer and secretary on the receipts and expenditures of the station for the fiscal year ended June 30, 1899; summaries of Bulletins 81-89 of the station, with an index to the bulletins; subject lists of regular and press bulletins issued by the station, and a general review of work in the different departments.

Twelfth Annual Report of Michigan Station, 1899 (*Michigan Sta. Rpt. 1899*, pp. 4, 5, 53-73, 79-367).—Contains the organization list of the station, a report of the secretary and treasurer for the fiscal year ended June 30, 1899, a report of the director, and departmental reports reviewing the different lines of station work during the year, a meteorological summary noted elsewhere, and reprints of Bulletins 161-174 of the station on the following subjects: Fertilizer analyses (E. S. R., 10, p. 734); relation of meteorology to forestry in Michigan, sketch of the original distribution of white pine in the lower peninsula, the present condition of Michigan forest and stump lands, forestry legislation, and methods of reforesting pine stump lands (E. S. R., 10, pp. 1020, 1045, 1046); strawberry culture (E. S. R., 10, p. 1043); methods and results of tillage (E. S. R., 11, p. 40); draft of farm implements (E. S. R., 11, p. 96); a grade dairy herd (E. S. R., 11, p. 188); a discussion of farm dairy methods (E. S. R., 11, p. 186); Michigan fruit list (E. S. R., 11, p. 153); notes from the South Haven Substation (E. S. R., 11, p. 252); vegetable tests for 1898 (E. S. R., 11, p. 250); bush

fruits for 1898 (E. S. R., 11, p. 252); combating disease-producing germs (E. S. R., 11, p. 390); killing the tubercle bacillus in milk (E. S. R., 11, p. 386); fertilizer analyses (E. S. R., 11, p. 528).

Eleventh Annual Report of New Hampshire Station, 1899 (*New Hampshire Sta. Bul.* 68, pp. 143-194, figs. 2).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1899, reports of the vice-director and chemist, horticulturist, agriculturist, entomologist, bacteriologist, and meteorologist, parts of which are noted elsewhere, and a list of station publications available for distribution. The report of the vice-director and chemist gives the results of analyses of several samples of city stable manure, spring water, and wood ashes.

Director's report for 1899, W. H. JORDAN (*New York State Sta. Bul.* 168, pp. 307-330).—The different lines of station work with the results obtained are reviewed at some length, and notes are given on the station staff, student assistants, needed changes and additions, inspection of fertilizers and feeding stuffs, and the publications of the station. Lists of bulletins published in 1899, and periodicals received by the station library are appended.

Eighteenth Annual Report of Ohio Station, 1899 (*Ohio Sta. Rpt.* 1899, pp. XVI+387-395, map 1).—The report contains an announcement relative to the character of the work undertaken at the station, the organization list of the station, a report of the treasurer for the fiscal year ended June 30, 1899, and a report of the director reviewing the different lines of station work and giving a list of acknowledgments. An index to the publications issued during the year and a subject list of station publications are appended.

Annual Report of Virginia Station, 1899 (*Virginia Sta. Rpt.* 1899, pp. 14).—This includes the organization list of the station, summaries of Bulletins 77-88 issued by the station during the year; a financial statement for the fiscal year ended June 30, 1899, and brief outlines of work in horticulture, entomology, mycology, biology, chemistry, veterinary science, and agriculture by the heads of departments.

Report of the agricultural experiment station at Kiel, 1899, A. EMMERLING (*Jahres-Bericht der agrikulturchemischen Versuchsstation in Kiel für 1899. Kiel: Vollbehr & Riepen, 1900, pp. 33*).—This is a summary account of investigations carried out at this institution during 1899, including fertilizer and feeding stuff inspections, miscellaneous analyses, and accounts of cooperative field experiments.

Proceedings of the thirteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations, A. C. TRUE, W. H. BEAL, and H. H. GOODELL (*U. S. Dept. Agr., Office of Experiment Stations Bul.* 76, pp. 112).—This is a detailed account of the proceedings of the convention. For a summary see E. S. R., 11, p. 405.

Organization lists of the agricultural colleges and experiment stations in the United States, with a list of agricultural experiment stations in foreign countries (*U. S. Dept. Agr., Office of Experiment Stations Bul.* 74, pp. 121).—The bulletin contains in addition to the organization lists a subject list of the publications of the experiment stations received by this Office during 1899, Federal legislation affecting agricultural colleges and experiment stations, and the rulings of the Post-Office, Treasury, and Agricultural Departments as to the construction of the act of Congress of March 2, 1887, establishing the stations.

Agricultural education in Austria (*Jour. Bd. Agr. [London],* 7 (1900), No. 1, pp. 84-87).—Outline of the agricultural educational system in Austria.

Cotton-trade schools in the South, J. A. STEWART (*Sci. Amer.*, 82 (1900), No. 22, p. 344, figs. 7).—A description of the schools established at Atlanta, Ga., and Clemson College, S. C., for the practical teaching of cotton manufacturing.

Observations and experiments to illustrate the principles of agriculture in elementary schools, W. FAWCETT (*West Indian Bul.*, 1 (1900), No. 3, pp. 240-259).

Elementary agricultural education, R. HARPER (*Agr. Gaz. New South Wales*, 11 (1900), No. 4, pp. 295-300, figs. 2).—An account is given of the author's experience in teaching agriculture and horticulture in a public school.

Norway; the agriculture of Norway in relation to the general development of the country, N. A. KRYUKOV (*Norregiya, selskoe khozyaistvo v Norvegi, v svyazi s obshchim razvitiem stranui. St. Petersburg: Russian Ministry of Agriculture and Crown Lands*, 1899, pp. 246).

Agriculture in Bosnia and Herzegovina (*Die Landwirthschaft in Bosnien und der Herzegovina. Sarajero: 1899, pp. 12+397, maps 21, pls. 20, dgms. 14*).—The topographical features of these provinces, their resources, population, crop production, animal production, etc., are discussed. The system of agricultural education adopted and the experiment stations and model farm are described at considerable length.

Australian agriculture (*Mitt. Deut. Landw. Gesell.*, 15 (1900), Sup. to No. 3, pp. 22, 33).

Colonial experiment stations, J. DYBOWSKI (*Les jardins d'essai coloniaux. Paris: Hachette & Co., pp. 40, figs. 13*).—Outline of the work of the French tropical colonial agricultural experiment stations, with illustrations and descriptions of some of the more agriculturally important plants of these regions.

Australian experimental farms (*Nature*, 61 (1900), No. 1587, p. 538).—A list of the experimental farms in New South Wales and their principal lines of work.

Explanation of some scientific terms met with in agricultural literature, E. H. GURNEY (*Agr. Gaz. New South Wales*, 10 (1899), Nos. 1, pp. 54-63; 2, pp. 171-185; 5, pp. 427-439).

Manual of a bibliographical repertory of the sciences related to agriculture arranged according to a decimal classification, V. VERMOREL (*Manuel du répertoire bibliographique des sciences agricoles établi d'après la classification décimale. Montpellier: Coulet & Sons; Paris: Ch. Béranger; Paris, Bruxelles, and Zurich: Institut International de Bibliographie*, 1900, pp. 239, figs. 2).

The modern farmer in his business relations, E. F. ADAMS (*San Francisco: N. J. Stone & Co., 1899, pp. 662*).—This is "a study of some of the principles underlying the art of profitable farming and marketing and of the interests of farmers as affected by modern social and economic conditions and forces." The different sections treat of the education of the farmer; the farmer as a business man and as a cooperator; the relations of the farmer to questions of tariff, export bounty, single-tax system, currency, labor questions, referendum, and socialism; and the character, object, and organization of the cooperative fruit-marketing societies of California.

The appendix contains considerable information in small compass concerning the Morrill and Hatch acts, agricultural courses and agricultural extension, books of interest to farmers, statistics relating to banks and to currency, Interstate Commerce Commission rulings, cooperation among farmers and others, etc.

NOTES.

COLORADO COLLEGE AND STATION.—W. Paddock, of the New York State Station, has been elected to the position of botanist and horticulturist, made vacant by the death of Mr. J. H. Cowen.

MARYLAND COLLEGE AND STATION.—Guy L. Stewart has resigned as assistant in plant pathology to accept a position as assistant industrial agent in charge of the agricultural interests of a prominent railroad line.

NEW YORK STATE STATION.—Andrew J. Patten began his duties as assistant chemist of the station August 1, and P. J. Parrot as assistant entomologist August 15.

OKLAHOMA STATION.—A. G. Ford has resigned as assistant chemist of the station in order to pursue graduate work in chemistry at the Pennsylvania State College.

WASHINGTON COLLEGE AND STATION.—S. W. Fletcher, assistant in horticulture at the New York Cornell Station, has been elected horticulturist.

WYOMING STATION.—Luther Foster, of the Utah Station, has been elected professor of agriculture and horticulture.

PERSONAL MENTION.—M. G. Kains, special crop culturist of the division of botany of this Department, has resigned to accept the position of horticulturist in the School of Practical Agriculture and Horticulture at Briarcliff Manor, N. Y.

NECROLOGY.—J. Kjeldahl, director of the Carlsberg laboratory, born August 16, 1849, died at Baden July 18, 1900. His best-known contribution to science is the method of determining nitrogen which bears his name.

EXPERIMENT STATION RECORD.

EDITOR: E. W. ALLEN, PH. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.¹
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH and V. A. CLARK.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.	
Report of the chemists, W. R. Perkins and E. B. Ferris	213
Determination of phosphoric acid available as plant food in soils and fertilizers, J. Plot.....	211
Determination of cane sugar in condensed milk, L. Grünhut and S. H. Riiber.....	211
The adulteration of cane-sugar sirup with glucose, H. D. Richmond	212
On the determination of the acidity of milk, M. Siegfeld	212
On testing food products for boric acid and borates with turmeric paper, E. H. Jenkins and A. W. Ogden.....	213
Analyses of borax, A. W. Ogden	214
Analyses of formaldehyde or formalin, A. W. Ogden.....	214
Miscellaneous analyses, E. F. Ladd.....	214
A new indicator, J. Formánek	213

¹ Absent on leave.

BOTANY.

	Page.
The North American species of <i>Chaetochloa</i> , F. Lamson-Scribner and E. D. Merrill	219
Studies of the time and rate of development of the potato tuber, L. R. Jones and W. A. Orton	214
Development of the buds of the wild plum, L. R. Waldron	215
The effect of centrifugal force upon the cell, D. M. Mottier	215
The destruction of chlorophyll by oxidizing enzymes, A. F. Woods	216
On the formation of proteids during the germination of wheat in darkness, J. Goldberg	216
Concerning the physiological functions of solanin, G. Albo	217
The inhibiting action of oxidases upon diastase, A. F. Woods	217
The inoculation of soil, G. W. Herriek	218
Annual report of the consulting botanist for 1899, W. Carruthers	218

METEOROLOGY.

Report of the meteorologist, J. E. Ostrander	220
Appendix to report of meteorologist, R. E. Trimble	220
Meteorological summary, J. S. Moore	220
Summary of temperature, rainfall, and sunshine, E. F. Ladd	220

WATER - SOILS.

Nature, value, and utilization of alkali lands, E. W. Hilgard	221
The geology of Louisiana, G. D. Harris and A. C. Veatch	221
Analyses of artesian well waters, W. R. Perkins and E. B. Ferris	222
Drinking water, C. H. Jones and B. O. White	222
Distilled water for drinking purposes, H. L. Bolley	222
Analyses of soils, W. R. Perkins and E. B. Ferris	222
Chemical methods for ascertaining the lime requirements of soils, H. J. Wheeler, B. L. Hartwell, and C. L. Sargent	222
Soil temperatures, R. E. Trimble	222

FERTILIZERS.

On the importance of different green-manuring plants in the economy of soil nitrogen during the fall months, H. C. Larsen	223
Further notes on organic nitrogen availability, C. H. Jones and B. O. White	224
Contribution to the knowledge of the injurious effect of nitrate of soda on vegetation, J. Stoklasa	225
Fertilizers, E. Fulmer and W. H. Heileman	225
Analyses of commercial fertilizers and manurial substances, C. A. Goessmann	225
Report of the chemist, C. A. Goessmann et al	226
Fertilizers, F. W. Morse	226
Report of analyses of commercial fertilizers for the fall of 1899, L. L. Van Slyke	226
Analyses of commercial fertilizers, J. L. Hills, C. H. Jones, and B. O. White	226
Fertilizers and fertilizing materials, C. H. Jones and B. O. White	226
Commercial fertilizers, J. H. Stewart and B. H. Hite	226
Analyses of licensed commercial fertilizers, 1900, F. W. Woll and A. Vivian	226

FIELD CROPS.

Report of the agriculturist, W. P. Brooks and H. M. Thomson	226
Report of the agricultural department, J. H. Shepperd	233
Report on experiments conducted by the Ontario Agricultural and Experimental Union, 1899	228

	Page.
Report of the Arkansas Valley Substation, H. H. Griffin.....	229
Field experiments, E. R. Lloyd.....	229
Field crops, 1899, F. C. Burtis et al.....	230
Progress of experiments in forage crops and range improvement at Abilene, Tex., H. L. Bentley.....	230

EXPERIMENT STATION RECORD.

VOL. XII.

No. 3.

The life of the late Sir John Bennet Lawes furnishes a remarkable example of individual zeal and munificence, directed to the promotion of agriculture and the advancement of agricultural science. Born to wealth and luxury, and inheriting an estate upon the management of which he entered with the keenest interest and business sagacity, the squire of Rothamsted early developed a spirit of inquiry which dominated his whole life. A keen observer and an untiring experimenter, he saw in every weed an unsolved problem, in every clod of soil a subject for study. For over 60 years he devoted a large share of time and thought from a busy commercial life to the solution of these problems of agriculture, converting a portion of his estate into an experiment station and providing the means for its maintenance. His thorough knowledge of the details of farming, coupled with his practical sagacity, enabled him to grasp at once the real bearing and importance of each new fact. His services to agriculture are known and recognized throughout the civilized world, but perhaps nowhere have they been more appreciated or had a greater influence than in this country. His name in connection with the famous Rothamsted experiments has for many years been a familiar one in the class room of the agricultural college, at the farmers' institute, and to readers of the agricultural press. The full measure of success which he achieved makes his life one of inspiration and unusual interest. The universal appreciation of his services and the close relations which he has borne to the American stations will cause the deepest regret at his death and a profound sense of loss to the cause of agricultural investigation. He died August 31, 1900, in his eighty-sixth year, "full of days and full of honors, and venerated by all who knew him."

Although Sir John's earlier education, obtained at Eton and Oxford, was mainly classical, he developed a fondness for chemistry which led him to spend some time in London in its study. Some of his earlier work was directed to the isolation of the alkaloids of medicinal plants. He entered upon the management of the paternal estate of Rothamsted at the age of twenty, and some three years later, in 1837, he commenced his experiments with soil in pots. This was before Liebig had

announced his theory of plant nutrition, and when knowledge regarding the requirements of plants and the way in which they secure their nourishment was in very crude state.

His earlier experiments led to the discovery of the value of transforming bone into superphosphate by the use of sulphuric acid. The importance and scope of this discovery was confirmed in more extensive experiments, following which he took out a patent on the process in 1842, and the next year established a fertilizer factory near London. He continued in the management of this business for nearly thirty years, during which time it remained one of the foremost industries of its kind in England. It was sold in 1872 for nearly one and a half million dollars. In 1867 a large factory was acquired for the manufacture of tartaric and citric acids, which his wise business management and ability likewise placed at the head of this branch of chemical manufacture. He continued to operate this factory up to the time of his death.

But the commercial life upon which he entered did not prevent the continuation of the work of investigation which had been undertaken with so much interest, and in 1843 the services of Dr. (now Sir) J. H. Gilbert were engaged to superintend the laboratory investigations. This scientific partnership continued to the close of Sir John's life. His love for the work never waned, and he maintained a close supervision of it. No one knew the experimental fields better than he did.

The development of the station with the flight of years and the extent and character of its investigations are too familiar to need description. With the aid of Dr. Gilbert the field experiments were enlarged and systematized until they occupied nearly 40 acres, the whole of the present series of plats being in operation by 1856. These field experiments have been models of excellence, and in their extent and the systematic regularity with which they have been conducted they are unique. Experiments with animals were taken up in 1847, and since then several hundred oxen, sheep, and pigs have been used in the study of a variety of problems relating to animal nutrition. The work on the composition of animals has become almost classic.

The first paper of Lawes and Gilbert was, as Sir Henry Gilbert once said, "subjected to merciless excision by the editor of the journal to which it was sent," and they secured its publication with difficulty. The collected reports now occupy nine volumes, and have been widely distributed.

The wide recognition of the Rothamsted work which came with time brought its founder many honors. "The Queen created him a baronet in 1882; universities gave him their degrees; societies bestowed upon him their medals. Prosperity could not spoil him. Quite free from personal ambition, he was always ready to give the credit of success to his fellow-workers." This spirit of modesty and generosity

endeared him to all who knew him. It manifested itself in his response at the Rothamsted Jubilee in 1893, which was largely a tribute to his life-long coadjutor. "Had it not been for the constant labors of Dr. Gilbert," he declared, "the affairs of Rothamsted would have been in a different state to that in which they now are."

In 1889 Sir John transferred the laboratories and experimental fields of Rothamsted to a board of trustees with an endowment of nearly a half million dollars, thus making liberal provision for continuing the investigations permanently.

The influence of the Rothamsted station upon agricultural investigation in this country has been very potent and far-reaching. Long before the experiment station movement in the United States its work was widely known and did much to prepare the way for agricultural investigation here. Many a professor of agriculture gained his first inspiration for experimental work from a visit to Rothamsted or from published accounts of the work conducted there.

Three things have contributed to make the influence of the Rothamsted station especially strong in this country. First, it was quite well known, especially among certain classes of readers of agricultural literature, and was regarded by many of them as a model. Being an English station, its literature was more accessible to many and intercourse with the station was quite frequent. Second, much of its work was of a more immediately practical trend and on a basis which appealed to the thoughtful farmer because he could understand its bearing. It enabled farmers to see in what way experiment stations might contribute to the promotion of their interests. It helped to popularize the movement. Finally, the conditions were more nearly similar to our own, our methods of agriculture more nearly approaching those of England, and the experiments had been carried on so long and with such thoroughness as to inspire unusual confidence in them.

Since the establishment of the stations the literature of the Rothamsted work has been at their command. The work and results have been explained in three series of lectures given in this country, and a considerable number of station workers have visited Rothamsted and been privileged to discuss agricultural problems and methods of investigation with its founder. Its influence on the field work of our stations has been very noticeable. The field experiments at Rothamsted are far famed for their excellence and for the systematic way in which they have been conducted. The methods of plat experimentation have there been worked out in all the nicety of detail, and this has saved our stations years of preliminary work on methods.

The Rothamsted field experiments derive their greatest value from the comprehensive plan on which they were laid out, which has enabled their scope to be extended from time to time so as to include new

phases of the questions under investigation as they develop; from the systematic and painstaking manner in which they have been continued through long periods, strengthening the confidence in the results; and from the full notes which have been taken at each stage and placed in permanent form. In some of these respects there is still opportunity for the American experiment stations to profit by the methods at Rothamsted, if field experiments are to continue to form so prominent a feature of their work.

There have been many evidences of Sir John Lawes's deep interest in the American stations. He was in correspondence with some of the leading advocates of the stations before their establishment, and has frequently expressed his admiration of the work which they are doing. Soon after the establishment of the stations Sir John sent twenty-six handsomely bound sets of the Rothamsted publications, prepared at large cost, to be distributed among the stations as far as they would go, and in 1897 he supplemented this gift by a second installment of twenty-six sets, so that practically every station has been provided with a set of these valuable papers. He also distributed about 800 copies of the outline "memoranda" of the Rothamsted investigations among our station workers. His friendly spirit was still further shown by his provision in the Lawes Agricultural Trust for a biennial course of lectures in the United States on the work at Rothamsted. He did this, as he said, in order that Americans should feel that they had a share in any of the benefits which might arise from the Rothamsted endowment.

This fraternity of interest has been helpful to the American stations and a source of much gratification. Rothamsted will continue to be to them an inspiration, and under the generous provision of its founder will undoubtedly maintain the same high position in which he placed it.

INTERNATIONAL CONGRESSES OF HORTICULTURE, VITICULTURE, AND AGRICULTURE AT PARIS.

WALTER H. EVANS, Ph. D.,
Office of Experiment Stations.

Among the congresses held at Paris the past summer in connection with the international exposition, those of horticulture, viticulture, and agriculture are likely to prove of special interest to readers of the Record. The following brief account is prepared from notes taken by the writer and from some of the published proceedings. The doings of the congresses of experiment stations and of agricultural instruction were noted in the preceding number of this journal (pp. 101, 102).

CONGRESS OF HORTICULTURE.

The International Congress of Horticulture was opened by M. Dupuy, minister of agriculture, in the Salle des Congrès, Paris, May 25, and continued three days. Permanent organization was effected with M. Viger president and M. Bergman general secretary, the vice-presidents being selected from the various foreign delegates and distinguished French horticulturists present.

The papers presented covered quite a range of horticultural topics and were discussed at length. The first was a report on progress made in the heating of greenhouses. Steam, it was said, has been employed since 1825, having been used at that time in England. Hot-water heating was advocated as easier of control, and by its use lower constant temperatures are possible than by the use of steam. Public gardens for different regions and the question of the ornamentation of public squares and promenades were discussed. The general principles of ornamentation and requirements for parks, squares, and streets were stated, and the kind of plants adapted to the different conditions indicated. The fourth paper treated of the causes of the clematis disease and its prevention, and led to considerable discussion. Different opinions were expressed as to its cause, some holding it to be due to nematodes, others that it was a question of nutrition. For destroying the nematodes, which are said to be species of Heterodera, the immersion of pots in water for 24 hours was recommended. For open-air culture no means of prevention were proposed. The art of the floral decorator, its development and utility as related to horticulture, was the subject of two contributions. In one the development of the

art was traced from very early times, while the other gave an account of the progress during the nineteenth century. It was shown that at the present time floral decorators in the vicinity of Paris require about \$2,000,000 of horticultural products annually.

A report was given on the practical prevention of some diseases of truck crops. One of the largest growers of Roman lettuce near Paris stated that by the use of eau celeste he had entirely overcome the very common loss accompanying the forcing of that crop. Prof. Maxim Cornu recommended the prevention of all similar diseases by spraying the ground at the time of seeding with copper solutions and mulching about the plants with material which had been previously soaked in copper sulphate. Hot-water heating for forcing vegetables was the subject of a paper in which the writer gave results with this system of heating in forcing melons, beans, strawberries, and tomatoes, all of which were profitably grown for the spring market. Carrots, salads, radishes, and cauliflowers did not prove profitable. Considerable difference of opinion was expressed regarding the method of application and composition of fertilizers for truck crops. The advocates of chemical fertilizers and of manures were insistent upon their views. The subject was referred to a subsequent meeting. The rôle of artificial fecundation in horticulture, as shown by some experiments with *Pelargonium zonale*, was the subject of a paper that occasioned considerable discussion. A brief paper was presented on the rôle of electricity in plant growth, in which the author expressed the belief that electricity increased the general vigor of plants. The application of seed selection to the production and fixation of new horticultural varieties was exemplified by two specimens of palms grown from seed from different parts of the parent cluster. Others taking part in the discussion asserted that in improvement of varieties the individual should be the unit of selection, and that repeated experiments tended to throw doubt upon the constancy of differences sometimes noted for seed from different parts of a plant.

Other papers were on the programme but were carried over to the next meeting of the National Horticultural Society of France.

After the adjournment of the congress the delegates and others visited the School of Horticulture and the nurseries and houses of a number of commercial horticulturists at Versailles, the trial farm of Vilmorin, Andrieux & Co., and mushroom caves near Paris.

CONGRESS OF VITICULTURE.

The International Congress of Viticulture was held June 12-16 under the presidency of M. Tisserand, honorary director of agriculture of France. The first session was taken up with reports and discussion on the subject of phylloxera. As means for combating this pest, submersion, the use of carbon bisulphid and potassium sulphocarbonate, and

resistant vines were all discussed, each method having its advocates. The second session was devoted to the consideration of resistant vines; the merits of various varieties and races of American vines as resistant not only to phylloxera but also to drought were pointed out. At the third session the general subject of grape diseases was considered under the guidance of P. Viala, of the Institute National Agronomique. Protection from frost and hail, and problems of vinification were discussed in the fourth session, while the fifth and last session was largely given up to commercial features of the wine industry, the relation of wine and hygiene, and the use of French geographical names of wine regions as trade names by wine producers in foreign countries. This latter practice was severely condemned.

CONGRESS OF AGRICULTURE.

The Sixth International Congress of Agriculture was held July 1-7 under the presidency of M. J. Meline, with M. E. Tisserand vice-president and M. Henry Sagnier general secretary, delegates being present from nearly all the leading nations of the world. The first of this series of congresses was held in Paris in 1889. Subsequent meetings have been held at The Hague, Brussels, Budapest, and Lausanne.

The congress was formally opened by M. Dupuy, minister of agriculture. After a few remarks he introduced the permanent president, who addressed the delegates on the general agricultural situation, contrasting the present conditions with those existing at the time of the first congress. At the conclusion of the address, permanent organization was effected and the congress divided into seven sections with presiding officers as follows: Rural economy, M. Ribot; agricultural education, M. Gomot; agronomy, M. Marquis de Vogüé; zootechny, M. Louis Passy; rural engineering, M. Séblin; tropical and sub-tropical agriculture, M. Develle; and vegetable pathology, M. E. Prillieux.

In the sections papers were presented and discussed, and in many instances referred back to the general session for further consideration.

In section 1, the causes of the low price of wheat, the rôle of agricultural syndicates in their relation to producer and consumer, and the measures to be adopted to prevent speculators from fixing prices were discussed at length.

Section 2 considered papers on agricultural education in universities, and M. Grosjean, inspector-general of agriculture of France, submitted a report on training schools, professional schools, and special schools of agriculture, horticulture, and viticulture. The discussion on these papers took a wide range, at the conclusion of which a statement was presented embodying the ideas of the section upon the necessities of agricultural education. Where such instruction is not

already given, it is suggested that elementary agriculture be taught in primary schools, or through the establishment of special winter schools or courses. As a means for elementary training these were especially commended. For the higher schools of agriculture, suggestions for their location, equipment, curricula, etc., were made, and it was suggested that the universities direct their courses more toward the application of the various sciences to agriculture.

Papers on the relation between geological formation and agricultural value of soils, the degree to which soil fertility may be determined by chemical analysis, and the utilization of water in agriculture were presented in section 3.

In section 4 the subject of bovine tuberculosis was the principal topic of consideration. Papers were read on its spread, prophylaxis, etc. The sanitary regulations of different countries were reviewed and the necessity of such measures pointed out to those nations not having such laws or regulations.

Section 5 considered papers on the improvement of the sugar beet by selection and cultivation, the use of alcohol in the industries, and the use of molasses and unrefined sugar as feeding stuffs. A number of delegates gave their experiences with sugar and molasses as feeding stuffs, the use of which seems to have been followed with remarkable results.

The sessions of section 6 were in the main given up to the discussion of colonial agriculture, particular attention being given to the conditions for the culture of sugar cane and cotton. It was believed by a number of those taking part in the discussion that the proper conditions for cotton culture would be found in many of the colonies of European countries.

Section 7 received papers on the rust of cereals, diseases of cane, diseases of coffee, the protection of useful birds and animals, etc. At the instance of this section the general session adopted a series of resolutions looking toward the establishment of an international conference committee on plant diseases and their control, the object being to study simultaneously the diseases of various economic plants. A provisional committee was appointed from those in attendance and was directed to organize the international commission and to outline the scope of its work. Those designated for this purpose are: Delacroix, Eriksson, Fischer-Waldheim, Laurent, Prillieux, Sorauer, and Went. To this list there were added by the section: Frank, Marshall-Ward, Wiesner, Rostrup, Galloway, Linhart, Targioni-Tozzetti, Cuboni, Jaczewski, Fischer, and Chodat. It was also determined to publish a periodical bulletin giving the practical results of the studies of the commission.

Among the subjects suggested for investigation by this commission is cereal rusts. It was recommended that the various nations where

cereal rusts abound authorize and encourage the study of these diseases and means for their prevention for at least five years, this study to include the investigation and breeding of resistant varieties to take the place of those now cultivated. On account of the danger of the spread of diseases of coffee, cacao, and sugar cane to countries not now affected, it was suggested that the importation of all living stocks be under strict governmental control and such exchanges be isolated for a year or more until all danger of infection is past. Attention was called to the necessity of recognizing the relation between low vitality of plants and their liability to disease, and of taking steps toward studying the proper hygiene of the plant.

On July 3 the subjects of agricultural education and the protection of useful birds and animals were considered in general session, having been referred to the general congress from their respective sessions. Consideration was also given the reports on the improvement of sugar beets, and from section 7 on plant diseases. In the afternoon the delegates visited the sewage works at Achères, where the sewage of Paris is disposed of. The filtration works have a superficial area of over 9,000 acres.

The general sessions of the congress on July 4 were taken up with reports on the improvement of races of stock, and on the question of wheat supply and demand, both topics being discussed at considerable length.

July 5 was given up to excursions to Verrières, the trial grounds of Vilmorin, Andrieux & Co., and to the farm of M. Henry Petit. This latter has been maintained as a model farm in this family since 1740.

At the general session of July 6 the subject of import and octroi duties as bearing on the price of agricultural produce was discussed, and reports received from the different sections. The afternoon session was given up to reports on agricultural insurance, cooperative bakers, use of alcohol in various industries, molasses for distilleries, agricultural syndicates, and agricultural cooperative associations.

At the morning session of July 7 in section 3 a report was made on the reclamation and bringing under cultivation of certain tracts of land near the sea. More liberal concessions on the part of the Government are required to make such enterprises successful in France at least. A paper on irrigation in France was read and discussed. It was stated that of between 6 and 7 million hectares of land capable of irrigation but 250,000 hectares have been improved in this way. The subject of mountain pastures and pasturage as bearing upon the question of reclamation of such regions was introduced and considered at some length. On account of the importance of the topic it was formally referred to the next meeting of the congress, two years hence, at which time reports are to be expected from all the nations taking part in the congress.

In section 4 the relation of the Government to horse breeding was discussed. The improvement of horses in France is largely effected through sires owned by the Government. The effect of mechanical means of locomotion as relating to horse raising was considered. The advent of automobiles is said to threaten the demand for medium and low grade horses, but for the higher-priced animals no fear was expressed.

Other section reports were presented, among them the suggestions for agricultural education in primary schools, and agricultural schools for women. In primary schools giving agricultural instruction, it was agreed that they should confine their efforts to a knowledge of the common rocks and soils of the region and elementary knowledge concerning the minerals contained, also the use of fertilizers, recognition of plants, seeds, insects, etc. The instruction in these lines should be supplemented with visits to some of the better farms in the neighborhood of the school, where various agricultural operations could be observed. The necessity and desire for dairy schools and schools of domestic economy for women were pointed out, and those countries possessing such institutions were commended. Traveling dairies and similar institutions received the sanction of the congress as beneficial. The control of fertilizers, foods, etc., in the interest of agriculture and for the repression of fraud was discussed and the desirability for a unification of methods of analysis and repressive measures was pointed out. The rôle of fields of demonstration and experiment as factors in advancing agriculture was shown and the more frequent establishment of such fields advocated. Reports were submitted on experiment stations, seed-testing stations, practical schools of agriculture, schools for the study of colonial agriculture, combating fungus and insect pests, mulberry culture, etc.

On July 7 the President of France gave a reception to the officers and delegates of the congress. After the reception a banquet was given at the Hotel Continental, which was largely attended by the members. Rome was selected as the place of the next meeting, which will be held in 1902.

At the close of the congress excursions were taken to the experiment station and national agricultural school at Grignon, School of Horticulture at Versailles, to the north of France, Douai, Lille, etc., where numerous model farms, distilleries, dairy and stock farms, vineyards, etc., were visited.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Determination of phosphoric acid available as plant food in soils and fertilizers, J. PLOT (*Oesterr. Chem. Ztg.*, 3 (1900), pp. 127-131; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 453, II, p. 510; *Jour. Soc. Chem. Ind.*, 19 (1900), No. 7, p. 675).—The solvent used by the author is claimed to resemble closely beet juice in respect to salts, and is prepared as follows: Dissolve 0.4004 gm. of ferrous sulphate, 1.4616 gm. of potassium sulphate, 3.7098 gm. of calcium nitrate, and 2.890 gm. of magnesium chlorid in 1 liter of water. Fuse 7.0566 gm. of crystallized sodium carbonate, 6.744 gm. of potassium carbonate, and 0.2 gm. of silicic acid in a platinum crucible, dissolve the fused mass in water and mix with 2.75 gm. of oxalic acid, 1.9840 gm. of malic acid, 2.2994 gm. of citric acid, 1.9396 gm. of tartaric acid, and then dilute to 1 liter. For use, these two solutions are mixed in equal parts: 25 gm. of air-dried soil, or 5 gm. of a fertilizer, are shaken for half an hour in a half liter flask with 500 cc. of the liquid. Phosphoric acid is determined in 200 cc. of the filtered extract thus obtained.

Determination of cane sugar in condensed milk, L. GRÜNHUT and S. H. RIIBER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 1, pp. 19-36).—The authors report a critical examination of the various methods employed in the estimation of cane sugar in the presence of milk sugar. In the analysis of condensed milk they consider inversion by hydrochloric acid of the highest importance when methods of reduction with Fehling solution, before and after inversion, are used. If the quantity of cane sugar in a sample is to be drawn from the reducing power after inversion, the reduction before and after inversion must be made under exactly the same conditions, as concentration of solution and length of heating materially influence the quantity of cuprous oxid deposited. The gravimetric methods of Ost and Kjeldahl are the only two known to the authors that fulfill this condition, and the Ost method has been proven both by Ost himself and by Schmöger to be practically valueless for determining milk sugar, leaving only the Kjeldahl method.

G. Bruhns has shown that a considerable error results from a slight decomposition of cane sugar by boiling 20 minutes with a very strong

Fehling solution, as directed in the Kjeldahl method. This error is due to the reducing power of decomposition products. Again, in the analysis of condensed milk by the reduction methods, the percentages of milk sugar will be entirely too high in consequence of the excessive deposition of cuprous oxid. These errors render necessary an empirical table of corrections for each absolute and relative amount of both sugars present. Moreover, it is incorrect, the authors claim, to calculate the amount of cane sugar from the difference of copper reduced by milk sugar before inversion and that reduced by milk and invert sugars after inversion, as the products of reduction of the two sugars cause simultaneous reduction that can not be added directly. They conclude, therefore, that it is impossible to determine accurately cane sugar in condensed milk by the reduction methods.

To obtain correct results by using the methods based on polarization before and after inversion and applying the formula of Clerget in the estimation of cane sugar, the authors had to adopt many safeguards.

It is claimed that the complex rotatory influence of milk sugar is rectified by treatment of condensed milk with boiling water and then cooling. The authors did not find that the specific rotatory power of cane-sugar solutions was materially changed by heating to 100° C., as did Richmond and Boseley.

In correcting for volume of casein and fat precipitated, the double dilution method was employed.

The authors' results were calculated by Clerget's formula as modified by Herzfeld. In correcting volume they object to using the official factor 0.962, as it is asserted to be applicable only to substances of a particular chemical composition. C. B. WILLIAMS.

The adulteration of cane-sugar sirup with glucose, H. D. RICHMOND (*British Food Jour.*, 2 (1900), No. 19, p. 178).—Glucose is used extensively in the sophistication of saccharine foods, especially golden sirup, to prevent, as the manufacturers claim, granulation caused by the crystallization of a portion of the cane sugar. The real reason, the author states, is to make more salable unpalatable sirup of good color which is obtained as a by-product in the refining of sugar. The saline taste of the crude refinery sirup is obscured by the addition of large quantities of cheap and comparatively tasteless glucose. This sirup, lacking sweetness, is consumed in much greater amounts than golden sirup, and its high content of potassium salts is thought to be liable to injure the consumer. If prevention of granulation were the sole object for the addition of glucose to golden sirup, then 5 per cent would be sufficient; but as much as 70 or 80 per cent has often been found incorporated. C. B. WILLIAMS.

On the determination of the acidity of milk, M. SIEGFELD (*Molk. Ztg.*, 14 (1900), No. 13, pp. 205-208). The results of experiments were rather unfavorable to the use of solutions of calcium hydrate pre-

pared from commercial line for the volumetric determination of the acidity of milk in ordinary dairy practice. Comparative tests were made of decinormal solutions of sodium hydrate, potassium hydrate, and barium hydrate for determining the acidity of milk. The results showed that from 1.4 to 2.6 cc. more of the decinormal barium hydrate was required to neutralize 50 cc. of milk than was required of either of the other standard solutions. Phenolphthalein in varying quantities was used as an indicator. Fourth, tenth, and twentieth normal solutions of sodium hydrate were compared. The weaker solutions gave a lower average percentage of acid. Milk was diluted with different quantities of water and alcohol, and the acid content determined. The percentage of acid was apparently lessened by the addition of water and increased by the addition of alcohol. Determinations showed no material difference in the acidity of milk at temperatures varying from 5 to 60° C. The acid content was slightly lower at higher temperatures. The reaction of the reagents used with the phosphates in the milk is discussed as explaining some of the varying results obtained. The author concludes that the dilution of milk in the determination of acidity is to be avoided and that sodium hydrate and potassium hydrate are preferable to barium hydrate, and may be used as well in tenth as fourth normal solutions.

A new indicator, J. FORMÁNEK (*Ztschr. Analyt. Chem.*, 39 (1900), No. 2, pp. 99-103).—An alcoholic solution of alizarin green B gives a carmine-red color with acids and green with alkalis. It is sensitive to carbonic acid. The color changes are very sharp, and the indicator can be used in artificial light as satisfactorily as in daylight.—C. B. WILLIAMS.

Report of the chemists, W. R. PERKINS and E. B. FERRIS (*Mississippi Sta. Rpt. 1899*, pp. 31-41).—This report gives analyses of soils from different parts of the State (see p. 222); of manure from animals fed cotton seed and cotton-seed meal, sorghum, and forage plants (E. S. R., 11, p. 1022); and artesian well waters (see p. 222); and describes briefly pot and field experiments on soils in progress at the station.

Reports of the chemical stations in Sweden for 1898 (*Meddel. K. Landthbr. Styr.*, 1900, No. 63, pp. 367-400).—The 8 regular chemical stations maintained in part by the Swedish Government examined during the year 54,067 different samples of agricultural products, of which number 44,599 samples were milk and other dairy products, 1,031 fertilizers, 793 soil samples, etc. The average results of the examinations, with brief discussions of the same, are given in the report.—F. W. WOLL.

On testing food products for boric acid and borates with turmeric paper, E. H. JENKINS and A. W. OGDEN (*Connecticut State Sta. Rpt. 1899*, pt. 2, pp. 153-155).—The authors found testing with turmeric paper much more satisfactory than the flame test. A study was made of the method of making the test. The following precautions are given:

“Free boric acid can not readily be identified by the turmeric-paper test if borates are present.

“The material to be tested must in all cases be acidified with hydrochloric acid in order to ensure a satisfactory reaction with turmeric paper.

"A considerable excess of hydrochloric acid must be added to the solution to be tested—one-thirtieth by volume of concentrated HCl is not too much.

"Perfectly decisive reactions need not be expected where less than one part of boric acid is present in 10,000 of water."

Detection of boric acid or borates, H. BORNRÄGER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 2, p. 92).

The separation and determination of formic, acetic, propionic, and butyric acids by Haberland's method, J. SCHUTZ (*Ztschr. Analyt. Chem.*, 39 (1900), No. 1, pp. 17, 18).

Boemer's method of detecting cotton-seed oil in lard, M. WEIBULL (*Meddel. K. Landtbr. Stry.*, 1899, No. 59, pp. 33-42).

On the chemical determination of the nutritive value of fodder beets, L. HELWEG (*Tidsskr. Landtbr. Plantearb.*, 5 (1899), pp. 178-189).—Discusses errors of sampling and analysis of beets.

On the presence of dextrose and levulose in the leaves of beets, L. LINDET (*Ann. Agron.*, 26 (1900), No. 2, pp. 103-113).

On the presence of mannocellulose in the ligneous tissue of gymnosperms, G. BERTRAND (*Compt. Rend. Acad. Sci. Paris*, 129 (1899), No. 24, pp. 1025-1029).

The furfuroids of plant tissues, C. F. CROSS, E. J. BEVAN, and J. S. REMINGTON (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 4, pp. 307-310).

Systematic analysis of glucose, S. STEIN (*Internat. Sugar Jour.*, 2 (1900), No. 20, pp. 405-412).

Some chemical notes on the composition of the cocoanut, J. E. KIRKWOOD and W. J. GIES (*Science*, n. ser., 11 (1900), No. 285, p. 951).

Analyses of borax, A. W. OGDEN (*Connecticut Sta. Rpt.* 1899, pt. 2, pp. 150-153).—The analysis of a number of samples of borax is reported.

Analyses of formaldehyde or formalin, A. W. OGDEN (*Connecticut Sta. Rpt.* 1899, pt. 2, p. 156).—Tabulated analyses are given of 4 samples of formalin. The percentage of formaldehyde ranged from 36.02 to 42.30.

Examination of foods, condiments, and commercial products, G. RUPP (*Die Untersuchung von Nahrungsmitteln, Genussmitteln und Gebrauchsgegenständen*. Heidelberg: Carl Winter's Universitäts-Buchhandlung, 1900; 2 ed., ill.)

Examination of the most important foods and condiments, C. BEIER (*Die Untersuchung unserer wichtigsten Nahrungs- und Genussmittel*. Leipzig: C. G. Naumann, pp. VIII+147; abs. in *Ztschr. Untersuch. Nahr. u. Genussmitl.*, 3 (1900), No. 4, p. 298). This work forms Nos. 116 to 118 of the series entitled "Medicinisches Bibliothek für praktische Aerzte."

Miscellaneous analyses, E. F. LADD (*North Dakota Sta. Rpt.* 1899, pp. 13, 14).—Analyses are reported of coal from western North Dakota, ashes from lignite, and clays (9 samples) from different parts of the State.

BOTANY.

Studies of the time and rate of development of the potato tuber, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt.* 1899, pp. 155, 156). Previous investigations on this subject (*E. S. R.*, 5, p. 988) have been repeated, using 75 rows of potatoes. All were planted at the same time on rather heavy clay soil, were sprayed with Paris green in the early part of the summer, and received 3 applications of the Bordeaux mixture in the latter part, so that the vines were in a fairly healthy condition quite late in the season. Beginning August

4, every ninth row was dug at intervals of 10 days. The total yield of tubers and yield of marketable size is given, showing that a considerable portion of the yield of marketable tubers was formed after September 1. The unsprayed vines in this experiment were nearly all dead before August 20. The results of this experiment lead the authors to repeat the former statement that "the potato crop of Vermont suffers far more each year than is generally realized from the premature death of the vines."

Development of the buds of the wild plum, L. R. WALDRON (*North Dakota Sta. Rpt. 1899, pp. 31-39, figs. 6*).—Investigations have been made on the time and manner of differentiation of leaf and flower buds, and the influence affecting the formation of flower buds; also a study of the reserve materials of the plant.

The present report is in the nature of a preliminary one, some phases of the work being still under investigation. Among some of the more important deductions drawn from the investigations, the author states that the stamens, pistils, and bud scales must be considered as modified portions of the tissues of the shoot axis and not as modified foliage leaves. In the plant investigated the number of flowers starting in a bud is 4, which may often be lessened by some being killed. Lignin is formed early in the life of the bud, and by September the lignified portion is sharply differentiated from the cellulose portion. The organic parts of the flower are formed before winter, the ovule in the spring. The most important time of differentiation of leaf and flower buds appears to be from the middle of July to the middle of August, although there is some evidence to show that it may take place later.

The effect of centrifugal force upon the cell, D. M. MOTTIER (*Ann. Bot., 13 (1899), No. 51, pp. 325-361, pl. 1*).—The author has undertaken to determine what parts of the living substance and its inclusions could be displaced within the cell by means of centrifugal force several hundred times greater than that of gravity, acting for a definite but usually short period of time, and to see what effect such displacement might have upon the individual cell.

Various algæ, leaves of mosses, trichomes of a number of plants, staminal hairs from *Tradescantia*, leaves of a number of plants, and seedlings of maize, beans, castor beans, and horse beans were used in the experiments. The centrifugal force was generated by the use of an ordinary milk separator driven by a gas motor. After subjecting the plants to this force for a number of hours it was found in the case of the algæ and mosses that the chlorophyll in the cells was all forced toward the distal end. This was also true of the contents of the cells of most of the other plants experimented with. After standing a time the normal condition of the distribution of the cell contents was resumed, at first rapidly but later very slowly.

The experiments with the seedlings of the plants mentioned were

largely conducted to determine the effect of centrifugal force on the nucleus. The results obtained bear directly upon the specific gravity of the various cell constituents, and especially those of the nucleus. It is stated that there can be no doubt that the nucleolus is relatively a very heavy body and that its specific weight is greater in the nuclei of cells destined to great constructive activity.

The destruction of chlorophyll by oxidizing enzymes, A. F. WOODS (*Centbl. Bakt. u. Par.*, 2. Abt., 5 (1899), No. 22, pp. 745-754).—The author reports on a series of studies made on the relation which exists between oxidizing enzymes and decoloration of leaves. Oxidizing enzymes, both oxidase and peroxidase, were found plentiful, and some of their characteristics are described, together with notes on their presence and effect on variegated maple, horse-chestnut, and a number of other plants. A careful comparative investigation showed that the intensity of the power of oxidase was inversely proportional to the amount of chlorophyll present, as judged by color. The peroxidase follows the same rule.

The principal portion of the investigation was conducted with tobacco, in which the so-called blanching or mosaic disease was examined with particular care. Peroxidase was always found in greater quantity and twice as strong in the light-colored areas as in the green ones, and where the chlorophyll had nearly disappeared, leaving albino spots, the oxidase was twice as abundant as in the green of the same leaf or the green of healthy leaves. The author claims that there is no good reason for separating this disease of tobacco from true variegation or albinism. He has been able to produce it at will, and as yet no organism has been isolated that proved to be the cause of variegation.

The conclusions of the author are that chlorophyll is rapidly destroyed by the oxidizing enzymes, oxidase, and peroxidase. These enzymes are normally present in small quantity in many of the higher plants, and under certain conditions either become more active or are produced in greater quantity, resulting in variegations and other forms of disease. The active agents in producing the mosaic disease of tobacco appear to be enzymes rather than the "living fluid contagion" suggested by Beijerinck (*E. S. R.*, 11, p. 167). The mosaic disease may be produced at will, and the enzymes can remain in the soil uninjured for several months. In aqueous solutions the oxidases are destroyed by 5 minutes' exposure to temperatures of 65 to 70° C., and the peroxidases by 5 minutes' exposure to temperatures of 80 to 85° C.

On the formation of proteids during the germination of wheat in darkness, J. GOLDBERG (*Rev. Gén. Bot.*, 11 (1899), No. 129, pp. 337-340, fig. 1).—A considerable number of grains of wheat were germinated in the dark, at temperatures ranging from 20 to 22.5°. At intervals of 3, 8, and 14 days the author removed 60 of the plantlets

of equal development, separated the embryo from the endosperm, and determined the protein and nitrogen according to the methods of Stutzer and Vigelandt. The results of the analyses are shown, from which the author claims that proteids are formed in considerable quantity by the embryos of wheat during the process of germination. It is further claimed that this increase could not have come from the endosperms by osmosis, but was formed in the embryo.

Concerning the physiological functions of solanin, G. ALBO (*Contrib. Biol. Vég.*, 2 (1899), No. 3; *abs. in Ann. Agron.*, 25 (1899), No. 12, pp. 621, 622).—Solanin has been previously regarded by different authors as a means of defense and as a transfer form of albumin similar to asparagin. The author studied the question by examining micro-chemically a number of species of *Solanum* grown under normal conditions, in shade and in an atmosphere lacking in carbon dioxide.

Solanin was found in the stems, leaves, tubers, and seeds of most species of *Solanum* grown under normal conditions. During and following germination it diminishes, but reappears with the development of the plant and is abundant in the adult plant. When grown in darkness, solanin gradually disappears, and negative reactions were obtained for a considerable time before the death of the plant. If the seeds of *Solanum sodomaeum* are germinated in the dark, there is a complete disappearance of the alkaloid. When the seedlings were brought into the light, the solanin reappeared soon after the chlorophyll functions were established. The same is true of the seeds of the eggplant, tomato, potato, and numerous species of *Capsicum*.

From the results of these experiments the author believes that solanin can not be considered a transfer form of the albuminoids, but is a true nitrogenous reserve material used by the plant during its first stages of development. On this account it is claimed that solanin can not be considered simply as a means of defense on the part of the plant against animals.

The inhibiting action of oxidases upon diastase, A. F. WOODS (*Science*, n. ser., 11 (1900), No. 262, pp. 17-19).—While engaged in a study of the mosaic disease of tobacco leaf, the author found that the lighter-colored areas contained more starch in the form of granules than the green areas of the same leaf. He has pointed out elsewhere (see p. 216) that these light-colored cells exhibit much more oxidizing activity than the green cells of the same leaf. In all examples there was a greater amount of oxidizing enzymes, oxidases as well as peroxidases, in the light-colored tissues. Mainly upon this evidence the author considered the light-colored tissues as the diseased portions of the leaves.

Recent histological studies of diseased leaves reveal important differences, which make it very clear that the light-colored areas are not normal. In badly diseased leaves the palisade parenchyma is not

developed at all in the light-colored areas. In leaves severely attacked by the disease, by simply looking across the leaf depressions may be observed where the light areas occur. The cells of the diseased areas translocate their starch with great difficulty and often become completely gorged.

The conclusion seems warranted that the tardiness in translocation of starch in the diseased area is due to the abnormal activity of the oxidizing enzymes in these cells, by reducing or weakening the activity of diastases.

The inoculation of soil, G. W. HERRICK (*Mississippi Sta. Rpt. 1899, pp. 42, 43*).—In the autumn of 1898, 3 plats of vetch were sown to note the effect of inoculation of the soil on this crop. The first plat was inoculated by soaking the seeds in water in which had been stirred soil from a field in which vetches had been previously cultivated. After being thoroughly wetted, the seeds were sown in drills and covered. Plat 2 was retained as a check plat, while plat 3 was inoculated by scattering dry dirt from the vetch field in the drills as the seed were sown.

The following May the plats were cut and carefully weighed, and it was found that plat 1 yielded 64.5 lbs.; plat 2, 48 lbs.; and plat 3, 79 lbs. of green forage. Pot experiments with vetch were attempted, but the results obtained were contradictory. Plats of crimson clover and alfalfa were sown and treated in the same manner as described for the vetches, but negative results were obtained on account of the non-germination and poor stand of the plants.

Annual report of the consulting botanist for 1899, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 678-688, figs. 13*).—Among the items reported upon by the consulting botanist are investigations on the germination of seeds, weeds, and diseases of plants. During the year the seeds examined were remarkably free from impurities and the germinations high, although in some cases there was considerable fluctuation.

On account of injury to stock, investigations were made with a number of plants which are either poisonous or represented to be, and a list of those mentioned include *Ranunculus acris*, *R. parviflorus*, *R. ficaria*, Celadine, *Arum maculatum*, laurels, *Nicotiana affinis*, *Heraclium sphondylium*, *Prunella vulgaris*, and *Nepeta glechoma*. A number of other plants are mentioned which were suspected of being injurious to stock, but which the author doubts having any noxious qualities.

Among the diseases reported upon were 2 diseases of wheat, one due to *Cladosporium herbarum*, the other to the mildew, *Erysiphe graminis*. A field of peas badly infested with *Pythium debaryanum* is reported upon, and *Ascochyta pisi* has proved troublesome on bean crops in a number of places. Attacks of *Plasmodiophora brassicæ* are

noted from two localities. Leaves of pear trees were identified by the author as affected by species of *Sphaeria*, the trees in this instance having nearly every leaf attacked.

A report is given on impurities found in a number of feeding stuffs, and a brief account of an investigation in which the effect of lightning on a number of trees is shown.

Saltbushes (*Queensland Agr. Jour.*, 6 (1900), No. 4, pp. 254-257, pls. 3).—Notes are given on a number of species of *Atriplex*, their habits of growth and possible value being described. Extensive quotations are given from California Station Bulletin 125 (E. S. R., 11, p. 636).

Botanical notes on wheat and spelt, A. S. HITCHCOCK (*Amer. Gard.*, 21 (1900), No. 295, pp. 556, 557).—Notes the classification of the different kinds of wheat according to the recognized species. *Triticum monococcum*, *T. polonicum*, and *T. sativum*. The latter is divided into *T. spelta*, *T. dicoccum*, *T. turgidum*, *T. durum*, *T. compactum*, and *T. vulgare*.

The North American species of *Chaetochloa*, F. LAMSON-Scribner and E. D. MERRILL (*U. S. Dept. Agr., Division of Agrostology Bul.* 21, pp. 44, figs. 24).—This bulletin contains a revision and enumeration of the North American species of *Chaetochloa*, commonly known as *Setaria*. According to the authors, 28 species are found in the region covered by the bulletin, 23 of which are native of North America, the others having been introduced from Europe. Six of the species are here published for the first time.

Botanical origin of caoutchouc and gutta-percha, P. GRÉLOT (*Origine botanique des caoutchouc et gutta-percha. Paris: Berger-Lerrault & Co., 1899, pp. 276, figs. 2*).—Descriptions are given of the plants producing caoutchouc and gutta-percha, with historical notes, chapters on methods of culture and handling, commercial movement, properties, composition, etc.

Poisonous plants, F. M. BAILEY (*Queensland Agr. Jour.*, 6 (1900), No. 5, pp. 382, 383, pl. 1).—Descriptive notes are given of the physic nut (*Jatropha curcas*).

The nutation of *Helianthus*, J. H. SCHAFFNER (*Bot. Gaz.*, 29 (1900), No. 3, pp. 197-200, figs. 10).—The nutation of wild and cultivated sunflowers is figured and described.

Can strontium and barium replace calcium in phenogams? U. SUZUKI (*Bul. Col. Agr. Imp. Univ. Tokyo*, 4 (1900), No. 1, pp. 69-79, pl. 1).—The author has investigated the possibility of substituting strontium and barium for calcium in the growth of plants, experiments being made in sand and water cultures. The results obtained indicate that these substances not only can not replace calcium but they are strongly poisonous to the plants. This poisonous action may to a certain degree be lessened by the addition of lime salts.

The nutrition of humus plants, R. Y. LEAVITT (*Amer. Gard.*, 21 (1900), No. 295, pp. 552, 553, figs. 3).—The nutrition of the Cupuliferæ, Betulaceæ, Ericaceæ, and Coniferæ by means of mycorrhiza is explained.

Some wood-destroying fungi, G. F. ATKINSON (*Geol. Surrey Louisiana, 1899, pp. 331-338, pls. 7*).—Notes are given on *Polyporus borealis*, *Hydnum septentrionale*, *Fomes fomentarius*, *Trametes pini*, and *Dædalea ambigua*.

The haustoria of the Erysipheæ, G. SMITH (*Bot. Gaz.*, 29 (1900), No. 3, pp. 153-184, pls. 2).—The structure and behavior of the haustoria of the powdery mildews, as shown by the author's investigations of a dozen species representing different genera, are described. Hitherto the minute structure and development of these organs seems to have been almost wholly unknown.

Nitrogen and Nitragin, L. C. NEWELL (*Pop. Sci. Mo.*, 34 (1900), No. 9, p. 164).—Popular notes.

Inoculation experiments with Nitragin, J. KÄPPELI (*Jahresber. Landw. Schule Rütli, 1898-99*, pp. 68-70).—A brief account is given of inoculation experiments with Nitragin on peas, vetches, and lupines in which average gains are reported of 4.3, 6.8, and 10.5 per cent, respectively.

Our botanic gardens, P. MACMAHON (*Queensland Agr. Jour.*, 6 (1900), No. 4, pp. 288-292, pl. 1).—Brief notes are given on 149 species of plants, mostly timber trees, the seeds of which are offered in exchange.

Report of the Natal Botanic Gardens, J. M. WOOD (*Durban, 1899*, pp. 14).—In addition to the routine report of the gardens and herbarium, economic notes are given upon a number of plants that are thought to be of value for that region.

METEOROLOGY.

Report of the meteorologist, J. E. OSTRANDER (*Massachusetts Hatch Sta. Rpt. 1899*, pp. 74-95).—A brief statement of the work of the year in this department of the station and monthly summaries of observations at Amherst, Mass., on pressure (maximum, minimum, mean, and range), temperature (maximum, minimum, and mean), dewpoint, relative humidity, cloudiness, sunshine, precipitation, wind movement, velocity, and pressure, snow, frost, etc., for 10 years (1889-1898), with normals and a general summary for the period. The following data are taken from the general summary:

Pressure (inches).—Maximum, 30.65, February 26, 1889; minimum, 28.24, February 8, 1895; mean, 30.029. *Air temperature* (degrees F.).—Maximum, 98, July 20, 1894; minimum, —19, February 3, 1898; mean, 47.1; mean annual range, 107; mean daily range, 22.1. *Humidity*.—Mean dewpoint, 40.2; mean relative humidity, 73.5. *Precipitation*.—Greatest annual, 1897, 57.05 in.; least annual, 1894, 32.64 in.; mean annual, 46 in. *Wind*.—Mean annual movement, 51,566 miles; maximum pressure per square foot, 43 lbs., September 11, 1895. *Weather*.—Mean cloudiness observed, 52.4 per cent; total cloudiness recorded by the sun thermometer, 22,400 hours, or 50.3 per cent; number of cloudy days, 1,444. *Bright sunshine*.—Number of hours recorded, 22,120, or 49.7 per cent.

Appendix to report of meteorologist, R. E. TRIMBLE (*Colorado Sta. Rpt. 1899*, pp. 96-104, 110-112, charts 2).—Tables give monthly and annual summaries of observations during 1898 and 1899 on temperature, humidity, precipitation, snowfall, dewpoint, days of frost or dew, cloudy and stormy days, and direction of the wind at Fort Collins, Rockyford, and Cheyenne Wells, and on temperature, precipitation, snowfall, and stormy days at Estes Park (at base of Longs Peak, elevation 9,000 ft.), Pinkhampton (elevation 8,400 ft.), and Gleneyre (elevation 8,000 ft.). The monthly and annual rainfall at Fort Collins (1872-1899) and at 7 additional places in the watershed of the Cache la Poudre River is also reported. Observations during 13 years (1887-1899) on the evaporation from a water surface are tabulated.

Meteorological summary, J. S. MOORE (*Mississippi Sta. Rpt. 1899*, pp. 45-47).—Tables are given which show the daily and monthly precipitation with departures from normal, monthly temperatures with departures from normal, cloudiness, and direction of the wind for the year ended June 30, 1899. The most remarkable feature of the weather during this period was the extreme low temperatures of February 11-14, 1899, during which the temperature fell to -8° F., and the continued cold and wet weather of March and April.

Summary of temperature, rainfall, and sunshine, E. F. LADD (*North Dakota Sta. Rpt. 1899*, p. 14).—Tables give the maxima, minima, and mean temperatures for each month of 1899; also the total rainfall, monthly and yearly, for 1899 and 7 preceding years, and the hours of sunshine. The rainfall during 1899 was 21.21 in.; the mean annual rainfall for 8 years (1892-1899) was 19.87 in.

Sunshine records at Aas Agricultural College, J. SEBELIEN (*Norsk Landmands-blad*, 19 (1900), No. 10, pp. 109, 110).—The author has made daily records of the amount of sunshine at the State Agricultural College of Norway (latitude about 59.5 deg. N.) during the past three years by the photographic method. The total amount of sunshine for the year 1897 was 1,700 hours, or 38.9 per cent of the number of hours during which the sun was above the horizon; in 1898 the amount was 1,632 hours 29 minutes (36.5 per cent of theoretical maximum), and in 1899, 2,197 hours 18 minutes (49.2 per cent of theoretical maximum). In midsummer the sun sets at about 10 p. m. at Aas, but owing to the small amounts of photographically active rays in the sunshine when the sun is near the horizon it was only possible to register sunlight a few times after 9 p. m. during 1898, and in 1899 no records were made after this time, the records as a general rule closing at about 8.15 p. m.—F. W. WOLL.

WATER—SOILS.

Nature, value, and utilization of alkali lands, E. W. HILGARD (*California Sta. Bul.* 128, pp. 46, figs. 16).—This is a general summary of the results of investigations at the California Station on this subject during the past 20 years, the details of which have been published in reports and bulletins of the station. The topics treated include occurrence and characteristics of alkali soils, how plants are injured by alkali, effects of irrigation, distribution of alkali salts in the soil, composition of alkali salts, utilization and reclamation of alkali lands, removing the salts from the soil, crops suitable for alkali lands, amount of salts compatible with ordinary crops, limits of saline content of waters used for irrigation, and reclaimable and irreclaimable alkali lands as distinguished by their natural vegetation.

The geology of Louisiana, G. D. HARRIS and A. C. VEATCH (*Louisiana Stas. Spec. Rpt. Geol. and Agr.*, pt. 5, pp. 354, pls. 53, figs. 3, maps 12).—This report summarizes previous work on the geological and agricultural survey of Louisiana (E. S. R., 10, p. 330) and gives an account of additional investigations on the same subject. The report is divided into three parts. The first is a historical review of investigations from the earliest times up to and including those of the Louisiana Experiment Stations. The second part deals with the general geology of the State, including stratigraphic geology and economic geology. Under the latter head are reported the results of observations on the occurrence, extent, and quality of the deposits of salt, sulphur, clay, sandstone, limestone, and gravel, which are classed as important products, and of the following unimportant products: Iron ores, lignite, lead and zinc ores, marl, gypsum, petroleum, and gas. The third part contains reports of investigations in special lines, including (1) the Natchitoches area, (2) the Shreveport area, (3) the Five Islands, (4) a report on Louisiana clay samples (by H. Ries), (5) a report on a collection of fossil plants from northwestern Louisiana (by A. Hollick), (6) the cretaceous and lower eocene faunas of Louisiana, (7) establishment of meridian lines, (8) a few notes on roadmaking, and (9) some wood-destroying fungi (by G. F. Atkinson, see p. 219). The

first of these reports deals with the topography, stratigraphy, soils, and springs of the area studied; the second with topography and drainage, the great raft in the Red River and its effects, the geology and soils of the bottoms, the geology of the hill lands, and aboriginal works on Caddo bottoms, etc. The notes on soils relate rather to "their general aspect and location than to their agricultural value." Discussion of the latter is deferred until analyses of the soils have been completed. The typical soil areas are mapped. The third report gives a history of the study of the Five Islands and the geographical position and a general topographical description of the islands, special attention being given to the occurrence, origin, and extent of the salt deposits and the history of their exploitation.

Analyses of artesian well waters, W. R. PERKINS and E. B. FERRIS (*Mississippi Sta. Rpt. 1899*, p. 41).—The mineral constituents of 6 samples of artesian well water are reported.

Drinking water, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1899*, pp. 145, 146).—Examinations with reference to sanitary condition of 4 samples of spring water, 12 of well water, and 2 of brook water are reported.

Distilled water for drinking purposes, H. L. BOLLEY (*North Dakota Sta. Rpt. 1899*, pp. 29-31, figs. 2).—Two cheap forms of apparatus suited to use on the kitchen stove are described.

Analyses of soils, W. R. PERKINS and E. B. FERRIS (*Mississippi Sta. Rpt. 1899*, pp. 31-35).—Chemical and mechanical analyses of 71 samples of soils from different parts of the State are reported.

Chemical composition of soil, J. A. MURRAY (*An. Rpt. on Field Expts. Agr. Dept. Univ. Col. Wales, 1899*, pp. 75-78).—A chemical analysis of a soil which had been in grass for several years and was rather badly drained.

Chemical methods for ascertaining the lime requirements of soils, H. J. WHEELER, B. L. HARTWELL, and C. L. SARGENT (*Rhode Island Sta. Bul. 62*, pp. 65-88).—For abstract of this article as published elsewhere, see E. S. R., 11, p. 1003.

The influence of lime on vegetation and the value of the calcimetric analysis of soils, A. GASSER and R. MAIRE (*Bul. Soc. Sci. Nancy, 2. ser., 16 (1899), No. 34*, pp. 32-41).—A study of the distribution of plants as determined by the lime content of the soil and of the value of the determination of lime in soils as a means of ascertaining the kinds of plants to which they are adapted. A bibliography of the subject is appended.

Moor culture at Tranekjær, Denmark, L. JÖRGENSEN (*Tidsskr. Landökon, 1900*, No. 6, pp. 301-323).

Soil temperatures, R. E. TRIMBLE (*Colorado Sta. Rpt. 1899*, pp. 105-109).—Tables give the weekly means of temperature at depths of 3 in. to 6 ft. in irrigated and unirrigated plats of soil on the college grounds during 1898 and 1899, and dates of extreme temperature in the irrigated plat during 1889-1899.

On the distribution of nitric-acid bacteria in some Danish soils, H. JENSEN (*Tidsskr. Landbr. Planteavl, 5 (1899), pp. 173-177*).—The investigations conducted by the author indicate that nitric-acid bacteria are not found in wild heather and moor soils, and that they appear very slowly in such soils under ordinary methods of culture. Their absence is most likely a result of the acid reaction of the soil, which is only neutralized by heavy liming or by formation of soil ammonia after several years (through aid of schizomycetes). It seems, furthermore, that the nitric-acid bacteria which appear when these new soils are cultivated are much less active than the bacteria in old cultivated soils.—F. W. WOLL.

FERTILIZERS.

On the importance of different green-manuring plants in the economy of soil nitrogen during the fall months, H. C. LARSEN (*Tidsskr. Landbr. Plantearb.*, 5 (1899), pp. 101-112).—Pot experiments were made with the following green-manuring plants: Buckwheat, yellow mustard, field pea, common vetch, hairy vetch, Roman vetch (*Vicia sativa narbonnensis*), yellow lupine, blue lupine, and white lupine, *Medicago lupulina*, common kidney vetch, serradella, *Melilotus alba*, and red clover. Five pots were used for each plant. The pots were filled with soil of a very light character, poor in humus and other fertilizing constituents, having been taken from a field on which crops of rye, barley, three years' pasture, and oats had been grown since the last manuring. An application of sulphate of potash and superphosphate corresponding to the contents of potash and phosphoric acid in a good crop of clover was added to all pots. The pots were 21 cm. deep and 20.2 cm. in diameter. The seeding and harrowing-under of the green-manure crops were done at such a time and in such a manner as would obtain in field work. Careful records were kept of the gross yields and those of dry matter obtained in each case, and nitrogen determinations were made in the soil in the pots at the beginning of the experiments, and after the crops had been harrowed into the soil. The average results of the experiments referring to the nitrogen balance are shown in the following table:

Nitrogen contents of pots before and after manuring.

Crop.	Nitrogen in soil per pot before experiment.	Nitrogen per pot after experi- ment.			Gain (+) or loss (—) in nitrogen.	
		In soil.	In crop.	Total.	Per pot.	Per acre (calculated).
	Grams.	Grams.	Gram.	Grams.	Gram.	Pounds.
Buckwheat	7.05	6.39	0.15	6.54	—0.51	—126
Mustard	7.04	6.71	.13	6.84	— .20	— 49
Field pea	7.11	6.97	.67	7.64	+ .53	+131
Common vetch	7.12	6.59	.77	7.36	+ .24	+ 60
Hairy vetch	7.05	6.91	.33	7.24	+ .19	+ 47
Roman vetch	7.12	7.16	.50	7.66	+ .54	+134
Yellow lupine	7.14	7.03	.20	7.23	+ .09	+ 22
White lupine	7.14	7.16	.17	7.33	+ .19	+ 47
Trefoil	7.05	7.09	.16	7.25	+ .20	+ 49
Serradella	7.05	7.03	.16	7.19	+ .14	+ 35
Melilotus	7.05	7.03	.38	7.41	+ .36	+ 88

While buckwheat and mustard caused an appreciable loss of nitrogen as compared with the content in the bare soil, the legumes supplied 4 to 5 times as much nitrogen as these crops, and made the soil considerably richer in nitrogen at the end of the experiments than before, the increase corresponding to about 15 loads of barnyard manure per acre.

The pots were placed under cover over winter, and in the spring

sown to six-rowed barley. The results obtained at harvest time were rendered valueless through an accident, but the appearance of the barley throughout the vegetative period clearly showed the superiority of the legumes as green manures, and the small crops in the buckwheat and mustard pots were ripe while the barley plants in many of the legume pots, notably the field pea and the common vetch pots, were large and still green.—F. W. WOLL.

Further notes on organic nitrogen availability, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1899, pp. 137-139*).—An account is given of further tests of the alkaline permanganate method for determining the availability of organic nitrogen in fertilizers (E. S. R., 11, p. 328). The results are given of trials of the method on the following nitrogenous materials: Acidulated fish (nitrogen, 6.72 per cent); tankage (6.43 per cent); high grade tankage (8.33 per cent); concentrated tankage (12.99 per cent); dissolved tankage (4.51 per cent); hair tankage, wool, horn, meat, etc. (9.10 per cent); garbage tankage, New York (3.15 per cent); garbage tankage, St. Louis (4.76 per cent); garbage tankage, St. Louis (2.11 per cent); dissolved horn and hoof (11.13 per cent); hog bristles (11.20 per cent); hair (9.82 per cent); fertilizer containing cotton-seed meal as its sole source of nitrogen (2.15 per cent); cotton-seed meal fertilizer (1.72 per cent); cream gluten meal (5.87 per cent); "gluton" (1.75 per cent); Atlantic gluten meal (12.43 per cent); cocoanut fiber feed (3.63 per cent). As in previous tests, equal quantities of material and quantities of material furnishing equal amounts of nitrogen were used.

"The misleading results obtained with equal quantities of material but unequal weights of nitrogen are as evident in this as in last year's work. When, however, equal amounts of nitrogen are taken (modified method) useful results are attained.

Animal ammoniates.—Not one of the better forms shows less than 56 per cent availability by the modified method, while the garbage and Philadelphia tankages, wool waste, leather and leather refuse, all of which are of well-known inferiority as fertilizers, show from 41 to 18 per cent availability. Hair tankage and hog bristles range unexpectedly high.

Vegetable ammoniates.—The modified method was found in last year's experience less satisfactory with vegetable than with animal ammoniates. It seemed probable that the low availability found with cotton seed, flax, and gluten meals, materials well known to be effective in actual field use, was due to the relatively large content of nonnitrogenous organic matter. This conjecture was borne out by the lowered results on high-grade animal ammoniates when filter paper, starch, etc., were digested with them, as well as by the higher figures obtained with a vegetable ammoniate after it has been acidulated for many months. In order to throw more light upon this question a highly proteinous vegetable by-product, Atlantic gluten meal, was secured. This material carried 7.04 per cent moisture, 0.42 per cent crude ash, 77.69 per cent crude protein, 0.24 per cent crude fiber, 13.59 per cent nitrogen-free extract, and 1.02 per cent ether extract. Although belonging to the same class of material as the other glutens, it showed 70.2 per cent nitrogen availability instead of 46 and 30 per cents. It seems safe to ascribe this result to the low percentage (14.85) of nonnitrogenous organic matter.

"It was pointed out in the last report that the more tedious pepsin-digestion process, which should be used as an adjunct to the modified permanganate method and in all cases of doubt, does justice to vegetable ammoniates."

Contribution to the knowledge of the injurious effect of nitrate of soda on vegetation, J. STOKLASA (*Ztschr. Landw. Versuchsw. Oesterr.*, 3 (1900), p. 35; *abs. in Chem. Ztg.*, 24 (1900), No. 20, *Reper.*, p. 65).—It was demonstrated by means of water cultures that rye is much more sensitive to perchlorate than barley or wheat, and particularly sugar beets, the latter being 10 times more resistant than the rye. In fact, it was found that copper and zinc sulphates and arsenic were more poisonous to beets than potassium perchlorate. Five hundred kilograms per hectare of nitrate of soda containing 2 per cent perchlorate may be applied to sugar beets without appreciable injury. For rye the limit is 100 kg. per hectare of 1 per cent perchlorate, while for oats the nitrate may contain 1.5 per cent perchlorate, and for wheat and barley 2 per cent.

Fertilizers, E. FULMER and W. H. HEILEMAN (*Washington Sta. Bul.* 40, pp. 32).—A general discussion of the principles underlying the use of fertilizers and of the sources and composition of fertilizers, with the text of the fertilizer law passed by the legislature of Washington and approved March 8, 1899. This law puts the inspection of fertilizers in charge of the chemist of the Washington Station, who is created State chemist *ex officio*. The chemist is authorized to collect samples, in person or by deputy, in the open market. An analysis fee of \$6 for each fertilizing ingredient contained or claimed to exist in the fertilizer offered for sale is required, the fees being paid into the treasury of the station. There is a provision against the use of pulverized leather, raw, steamed, roasted, or in any form, without an explicit statement of the fact. Violations of the law are punishable by a fine of \$50 for the first offense and \$100 for each subsequent offense. Fertilizers selling for less than \$10 per ton are exempt.

Sea algæ as fertilizers, C. SÖRENSEN (*Landmandsblad*, 33 (1900), No. 8, pp. 109-112).

Experiments with urine and liquid manure, N. A. HANSEN (*Landmandsblad*, 33 (1900), No. 7-8, pp. 77-79, 98-101).

Local fertilizer experiments in Denmark and Germany, M. WEIBULL (*Meddel. K. Landtbr. Styr.*, 1899, No. 11, pp. 1-26).

On the application of artificial fertilizers, F. H. WERENSKIOLD (*Norsk Landmandsblad*, 19 (1900), No. 20, pp. 224-228).

Analyses of commercial fertilizers and manurial substances, C. A. GOESSMANN (*Massachusetts Hatch Sta. Bul.* 65, pp. 14).—This bulletin gives instructions regarding the sampling of fertilizers, discusses the trade values of fertilizing materials, and reports analyses of 62 samples of fertilizing materials, including wood ashes, cotton-hull ashes, cotton-seed meal, tankage, sewage sludge, cork dust, kiln dust from breweries, cotton waste, tobacco refuse, muck, soils, bone, and compound fertilizers.

Report of the chemist, C. A. GOESSMANN ET AL. (*Massachusetts Hatch Sta. Rpt. 1899, pp. 108-122*).—This is a brief general account of the fertilizer inspection and of general work in the chemical laboratory of the station. It includes tables showing the average composition and agreement with guarantees of the fertilizers examined in 1898 and 1899; trade values of fertilizing materials; the quality of wood ashes analyzed in 1898 and 1899; analyses of 2 samples of hen manure; a list of licensed fertilizer dealers in Massachusetts, and miscellaneous notes on fertilizers.

Fertilizers, F. W. MORSE (*New Hampshire Sta. Bul. 69, pp. 14*).—This bulletin includes a schedule of trade values of fertilizing materials in 1899, brief statements regarding the fertilizer inspection, and tabulated analyses of 97 samples of fertilizers examined for the State Board of Agriculture during 1899.

Report of analyses of commercial fertilizers for the fall of 1899, L. L. VAN SLYKE (*New York State Sta. Bul. 173, pp. 531-552*).—The results of analyses of 130 different brands of fertilizers are reported. Of these 101 were complete fertilizers in which the nitrogen varied from 0.59 to 4.91 per cent, averaging 1.65 per cent. The available phosphoric acid varied from 3.44 to 13.08 per cent, averaging 9.04 per cent. The potash varied from 0.48 to 10.75 per cent, averaging 4.3 per cent. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed averages by 0.13, 0.74, and 0.22 per cent, respectively.

Analyses of commercial fertilizers, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul. 77, pp. 141-162*).—This bulletin discusses the valuation of fertilizers and reports analyses and valuations of 39 samples of fertilizers licensed for sale in the State up to April, 1900, with tables showing the average composition of all fertilizers examined by the station during the past 5 years.

Fertilizers and fertilizing materials, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1899, pp. 148-150*).—Analyses of 15 samples of home-mixed fertilizers, 28 samples of wood ashes, 7 samples of muck, 1 of cotton waste, and 2 of miscellaneous materials are reported.

“Twenty-six samples [of ashes], said to be unleached, varied from 3.24 to 9.76 per cent soluble potash, 3.66 to 10.05 per cent total potash, 1.06 to 3.41 per cent total phosphoric acid, 19.92 to 55.80 per cent lime, and averaged 5.27, 6.05, 1.68, 34.82 per cent, respectively, in the same ingredients.”

Commercial fertilizers, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul. 63, pp. 115-152*).—This gives the text of the State fertilizer law, statistics of the value and consumption of fertilizers in West Virginia during the last 5 years, and analyses and valuations of 204 brands of fertilizers registered for sale in the State during 1899. It is estimated that the consumption of commercial fertilizers of all classes in the State increased from 21,559 tons in 1895 to 39,106 tons in 1899, or 81 per cent. The greatest increase was in case of acid phosphate with potash—368 per cent.

Analyses of licensed commercial fertilizers, 1900, F. W. WOLL and A. VIVIAN (*Wisconsin Sta. Bul. 81, pp. 10*).—This bulletin gives the text of the State fertilizer law and reports 7 analyses of fertilizers with explanatory notes

FIELD CROPS.

Report of the agriculturist, W. P. BROOKS and H. M. THOMSON (*Massachusetts Hatch Sta. Rpt. 1899, pp. 9-49*).—This report covers fertilizer, soil, and variety tests with a number of field and garden crops, and is in continuation of similar work previously noted (*E. S. R.*, 10. p. 626). Pot experiments have been made with potatoes, onions, soy beans, corn, and millet.

Corn was grown on plats used continuously for 11 years in soil tests with different fertilizers, alone and combined. The experiments of 1898 with corn on the same plats had shown a decrease in yield on the plat which had received annual applications of muriate of potash at the rate of 160 lbs. per acre. It was thought that the continued use of the muriate form of potash had resulted in depleting the soil of lime, and hence lime at the rate of 1 ton per acre was added to the plats in 1899. The results were very beneficial on the muriate plat, the yield of shelled corn being at the rate of 49.75 bu. per acre. Other experiments, not recorded in detail, show "that the benefit from the lime was not due to the fact that it corrected soil acidity." The yield of shelled corn on the plat which received barnyard manure at the rate of 5 cords per acre for each of the 11 years of the test was at the rate of 75.88 bu. per acre, while the yield on the plat receiving complete commercial fertilizers was at the rate of 72.88 bu. per acre. Five cords of barnyard manure would cost if purchased about \$25, while the complete fertilizers cost about \$10. The financial profits for the whole 11 years with the different crops grown are in favor of the complete commercial fertilizers.

A soil test similar in character to the above was made on another series of plats which have been 10 years under trial. Onions were grown in 1899 and one-half of each plat limed at the rate of 1 ton per acre. The yields on the limed and unlimed portions of each plat are tabulated and the results obtained in the years 1898 and 1899 discussed. Beneficial effects of the lime on the muriate of potash plats were again shown, and it is concluded from the experiment that the muriate of potash is an undesirable form of potash for onions.

In a comparison of the relative value of 8,825 lbs. of barnyard manure alone vs. 5,880 lbs. of barnyard manure and 40 lbs. of high-grade sulphate of potash for corn, the best and cheapest yields were made by the combination of the lesser amount of barnyard manure with the potash. The results of a comparison for 9 years of a special corn fertilizer with a fertilizer containing a larger amount of potash for corn were slightly in favor of the special corn fertilizer, but it is believed "by the frequent introduction of clover the fertilizer richer in potash will prove superior to the other."

Tests have been under way for a number of years with muriate vs. sulphate of potash for a number of crops. In 1899 the largest yield of sugar beets was obtained on the muriate plats, but the sugar content and the degree of purity of the juice were higher in beets grown on the plats fertilized with sulphate of potash. The results obtained with the 2 fertilizers as regards yield and composition of both sweet and field corn were practically identical. With cabbage the greater number of hard heads and the greater total yield was afforded by the plats fertilized with the sulphate of potash.

A test with 7 different forms of potash for soy beans was begun in 1898 and continued with potatoes in 1899. All the different forms used increased the yields, but the yields from the same potash salt on the duplicate plats did not always occupy the same relative rank. The best average yield for potatoes was obtained on the high-grade sulphate plat. Plats receiving carbonate of potash-magnesia ranked second, and the low-grade sulphate plats third. Kainit ranked lowest in yield of all the salts employed.

Experiments with leguminous crops as nitrogen gatherers seemed to show no benefit to the succeeding crops from growing soy beans. Clover gave nearly as good average results on plats which had received no nitrogenous fertilizers for 11 years as on the plats which had been well fertilized with different forms of nitrogen during that time. Tests of different forms of nitrogen for farm crops showed them to rank on the average in the following order: Nitrate of soda, barnyard manure, dried blood, and sulphate of ammonia.

Experiments have been under way since 1891 to test the relative value for garden crops of (1) sulphate of ammonia, nitrate of soda, and dried blood as sources of nitrogen, and (2) muriate and sulphate as sources of potash. Partially rotted stable manure was applied to all the plats in 1898 and 1899. Barnyard manure alone has given the best results with celery, spinach, onions, table beets, and squashes. Sulphate of ammonia, when used with barnyard manure, was the most satisfactory form of nitrogen for strawberries and cabbages, and nitrate of soda the most satisfactory form for celery, lettuce, spinach, and onions. Of the 2 forms of potash, the sulphate gave the best results with strawberries, celery, lettuce, spinach, onions, and cabbages.

Data for tests of 94 varieties of potatoes are tabulated. Some 36 varieties produced yields averaging over 333 bu. per acre. In the author's opinion good Northern-grown seed is of more importance than name. The following varieties have made good yields for 3 years or more: Beauty of Hebron, Dutton Seedling, Early Rose, Enormous, Fillbasket, Prolific Rose, Restaurant, State of Maine, Thorburn, Vanguard, and White Elephant.

The experiment in using wood ashes, ground bone and muriate of potash, and barnyard manure in rotation upon grass lands has been continued. The average yields of hay and rowen obtained from the plats fertilized with the different manures since 1893 have been as follows: Barnyard-manure plats, 7,027 lbs.; bone and potash, 6,568 lbs., and wood ashes, 6,294 lbs. per acre.

Report on experiments conducted by the Ontario Agricultural and Experimental Union, 1899 (*Ontario Agr. and Expt. Union Rpt. 1899, pp. 22-41*). The summarized results obtained by the union in experiments with certain field crops and fruits are reported. The experiments involved tests of commercial fertilizers for corn and

mangel-wurzels; variety tests with millet, grasses, clovers, buckwheat, spring wheat, spring rye, barley, oats, field peas, field beans, Japanese beans, carrots, mangel-wurzels, sugar beets, and Swedish and fall turnips; tests in growing grass, peas, and 2 varieties of vetches for green fodder, 3 mixtures of grain for green fodder, 6 varieties of corn for grain fodder or silage; sowing peas at different dates to determine the amount of injury done by the pea weevil; planting potatoes the same day and 5 days after being cut; and planting corn in rows and in squares.

In the experiment in planting peas at different dates it was found that the percentage of weevily peas as well as the total yield decreased as the date of seeding advanced, the yield of peas sown on June 6 being only about one-third as great as from peas sown on April 30. Planting seed potatoes immediately after they were cut yielded on the average 12 bu. more per acre than was obtained from seed planted 5 days after being cut. Corn grown in squares gave a larger yield than when planted in drills, the experimenters deciding in the proportion of 14.1 in favor of planting by this method.

Report of the Arkansas Valley Substation, H. H. GRIFFIN (*Colorado Sta. Rpt. 1899, pp. 55-70, fig. 1*).—A report on the culture and yield of wheat, corn, alfalfa, plants for green manuring, pasture and forage, cantaloupes, potatoes, celery, sugar beets, beans, and certain orchard and small fruits. In some cases results of irrigation experiments are included. The results of a feeding test are noted elsewhere in this issue (p. 275).

Three irrigations proved as effective as 7 for cantaloupes. The yields in both cases were larger than where only one irrigation was given, but the quality of the cantaloupes was more satisfactory with the one irrigation. Cantaloupes grown on alfalfa sod gave better yields and fruit of better quality than when grown on other soils and fertilized with barnyard manure or bone dust. Transplanting vines started in the greenhouse gave a larger proportion of early fruits than was obtained when the seeds were grown in hills in the open field.

Paris green was used effectively as a remedy against the black flea-beetle, and Bordeaux mixture against the leaf blight of cantaloupes. The percentage of sugar in the juice of the sugar beets grown varied from 13.8 to 16.9, and the purity from 80 to 86.8. Some data are given on the cost of growing sugar beets, but they are not reduced to any common unit of comparison.

Field experiments, E. R. LLOYD (*Mississippi Sta. Rpt. 1899, pp. 9-13*).—Variety tests with cotton and wheat, fertilizer tests with cotton, and culture experiments with hairy vetch (*Vicia villosa*) are briefly reported.

The heaviest yields of the 20 varieties of cotton grown were afforded by Hawkins Jumbo and Texas Bur, each producing over 700 lbs. of

seed cotton per acre. In a fertilizer test with cotton, the use of 2,000 lbs. of compost applied in the drill resulted in heavier yields than cotton-seed meal, lime, acid phosphate, or kainit, alone or combined.

The heaviest yields of wheat were afforded by Eclipse, Beardless Fulcaster, Fulcaster, and Red May, the yields varying from 18.9 bu. in the first instance to 11.45 bu. in the last.

Sowing hairy vetch broadcast at the rate of 53 lbs. per acre resulted in a heavier yield of seed than sowing either 83 or 37 lbs. in drills 2½ ft. apart. Heavy freezing did not injure early sowings of vetch.

Field crops, 1899, F. C. BURTIS ET AL. (*Oklahoma Sta. Bul. 44, pp. 12*).—Variety tests with oats and culture experiments as regards time of seeding, thickness of planting, and methods of plowing and cultivation are recorded with Kafir corn, Indian corn, castor beans, and cotton. The data of the different experiments are tabulated. The authors summarize the results obtained as follows:

“(1) With oats, early seeding of an early-maturing variety has given best results.

“(2) With Kafir corn, planting about the middle of May in rows 3 ft. apart with one stalk each 3 to 5 in. has generally given the highest yields.

“(3) With corn, no definite differences in yield were produced by variations in thickness of planting or in methods of plowing and cultivation.

“(4) With castor beans, no difference in yield was obtained from planting weekly from March 21 to April 26. Planting May 16 gave the lowest yield. Manuring more than doubled the yield.

“(5) With cotton, tests of time and thickness of planting gave no conclusive results. Planting from April 15 to May 15 in rows 3 to 3½ ft. apart, and chopping to 1 stalk to each 18 in. is the general practice of cotton growers in eastern central Oklahoma.”

Brief notes are added to the bulletin on the experience of farmers of the Territory in cotton culture and on the growth of cowpeas at the station.

Progress of experiments in forage crops and range improvement at Abilene, Tex., H. L. BENTLEY (*U. S. Dept. Agr., Division of Agrostology Circ. 23, pp. 20, fig. 1*).—The general plan of these experiments, begun in 1898, has been previously outlined (*E. S. R.*, 10, p. 1005). This report covers the second year of the test. As a result of the cultivation and rest given, the grazing capacity of the range under observation has doubled after a little more than one year's treatment. The author concludes “(1) that it will pay farmers and stockmen of Texas, especially in the semiarid districts of the State, to cultivate their pastures by use of disk and iron-tooth harrows; (2) that it will pay them to rest their pastures periodically during the seasons when the grass seeds are maturing and falling to the ground.”

A further experiment has been added to those already under way in plowing furrows about 12 ft. apart in the pastures and running crosswise to the generally prevailing winds. The purpose of the furrows is to catch the grass seeds of the pasture which ripen and may

otherwise be blown away. They further serve to catch and hold surplus rain water. Pasture lands thus treated have given good results, many grass seeds being caught in the furrows, and the grass on each side has remained green for a much longer period than elsewhere. Transplanting grass roots on patches made bare of vegetation by overgrazing has been successfully accomplished.

A large number of grasses, legumes, and other forage plants have been tested on experimental plats. These are reported upon in detail. The weather conditions of the season were very unfavorable, but in spite of this drawback the experiments have yielded results of considerable value.

"They have demonstrated the availability of alfalfa (especially oasis alfalfa), sulla, sainfoin, smooth brome, Canada rye grass, Terrell grass, and others for use in permanent pastures and meadows; of the vetches, cowpeas, velvet bean, soy bean, teosinte, and a larger number of varieties of the sorghums and millets for annual or temporary pastures, and as sources of coarse forage, either fresh or cured; of salt-bush for alkali soils; of the gramas, Canada rye grass, grapevine mesquite, curly mesquite, galleta, and needle grass for reseeding the worn-out ranges. They have shown the feasibility of range improvement by resting and scarifying the land and by sowing hardy native and introduced grasses."

An experiment was made in baling legumes and sorghums. Several varieties of beans and peas were planted and when the fruits were nearly grown, but before they began to turn yellow, the vines were cut and cured as hay, after which they were baled. "Recent examination showed that the hay was as sweet as when first baled." A similar experiment was successfully carried out with sorghum. The stalks were cut when they were from 3 to 5 ft. tall and when the seeds were in the dough stage. The sorghum kept well and the bales were easily handled. Since these crops can be grown in all parts of Texas nearly every year, it is thought that the industry may become of considerable commercial importance in supplying forage to sections of country farther west.

Egyptian cotton in the United States, L. H. DEWEY (*U. S. Dept. Agr., Division of Botany Circ. 26, pp. 9*).—This circular reviews the results obtained in the earlier and in the more recent experiments with Egyptian cotton in this country, giving descriptions of 3 varieties of Egyptian cotton and instituting a comparison of the soil and climatic conditions of the 2 countries relative to cotton-growing areas. Egyptian cotton, apparently fully equal to the imported product, has been successfully grown in southern Texas from selected acclimated seed, and a successful hybrid has been obtained by crossing Mitafifi Egyptian with Myers Big Boll. The hybrid is said to produce a fiber very similar to the Egyptian product and in some respects superior to the Egyptian. In the opinion of the author the area which can be devoted to the culture of Egyptian cotton on a commercial scale in this country must necessarily be confined to the Gulf coast region, where the season

is long, and to the irrigated lands of the Southwest, the climatic and soil conditions of these regions being more similar to the Egyptian conditions than elsewhere in the United States.

Cowpeas and corn for silage and fodder, W. GETTYS (*U. S. Dept. Agr., Division of Agrastology Circ. 24, pp. 10, figs. 2*).—The desirability and practical possibility of growing corn and cowpeas together for silage and forage purposes are set forth by the author, his own experience in growing, handling, and feeding these crops being made the basis of the discussion.

Details as regards the author's methods of planting, cultivating, and harvesting the crops together are given. Whip-poor-will cowpea is considered the best variety for growing with corn. No noticeably injurious effect on the quality of the butter has been observed from feeding corn-and-cowpea silage to milch cows. Sowing cowpeas as a catch crop after wheat proved profitable in the author's experience. The pea vines were used for forage and the peas saved separately.

Influence of the time of harvesting on the yield and quality of hops, W. BEHREND (*Bl. Gersten, Hopfen, und Kartoffelbau 1 (1899), No. 12, pp. 465-483*).—Hops were gathered at regular intervals of 5 days each from August 25, when they were of a pure green color, to September 14, when they were of a yellowish color, flecked with reddish specks. The yields of fresh and air-dried hops, amount of resin and coloring material in the hops at different dates of gathering, and the character of the beer made with them were determined.

The late harvested hops gave the more satisfactory results in nearly every respect. In yield of air-dry substance and resin content, and in the taste and character of the beer made from the hops, each later harvest surpassed the one preceding. Relative to the fermentation period, acid content of the beer, and the color of the beer, no differences traceable to differences in the harvesting period could be detected. The content of coloring material in the hops decreased with the lateness of the harvesting.

The results of the investigation lead to the conclusion that the best time for harvesting hops is shortly after the appearance of the characteristic yellow color and reddish-colored flecks.

Influence of size of seed tubers on the yield of potatoes, CLAUSEN (*Landw. Wechubl. Schleswig-Holstein, 50 (1900), No. 4, pp. 62-64*). Experiments were made in planting Danish, English, and Blue Six Weeks seed potatoes of different sizes under like conditions on good soil. In every instance the greatest yields were obtained from the largest-sized seed, and the largest proportional gains were made by the early Blue Six Weeks potatoes. The author draws the following conclusions from the results obtained in the experiments: Large seed tubers insure, through the greater amount of nourishment which they furnish to the young plants, a stronger growth and a bet-

ter yield than small tubers. This result is especially noticeable in dry seasons. Early maturing varieties are more benefited by planting large seed tubers than varieties having a longer period of vegetation. Large seed tubers are especially desirable in light soils.

Culture of wheat and oats on the experimental fields at Grignon, P. P. DEHÉRAIN (*Ann. Agron.*, 26 (1900), No. 1, pp. 20-33).—The relative values of large and small grains for seed wheat, and the proper place for oats in a system of field rotation were investigated. Both crops were sown in fields on which crops of beets, potatoes, or clover had been cultivated the preceding season. The yields of wheat obtained from the plats seeded with large grains were slightly better than those where small seed had been used. The best results with both wheat and oats were obtained on the plats which had grown a crop of beets the preceding season, and the poorest results from the field which had been in clover.

Report of the agricultural department, J. H. SHEPPERD (*North Dakota Sta. Rpt.* 1899, pp. 41-45).—A short outline review of the work of the department during the year, with a reprint of the conclusions in bulletins 38 to 40 of the station.

Report of barley experiments in Denmark during 1898, C. SONNE (*Tidsskr. Landbr. Plantearb.*, 5 (1899), pp. 148-172).

Report of culture experiments with malt barley during 1897, C. SONNE (*Tidsskr. Landbr. Plantearb.*, 5 (1899), pp. 39-62).

Malt barley and its culture in Norway, A. KROGVIG (*Tidsskr. Norske Landbr.*, 7 (1900), No. 4, pp. 145-155).

Studies of plant variation and improvement, with special reference to Goldthorpe barley, W. JOHANNSEN (*Tidsskr. Landbr. Plantearb.*, 5 (1899), pp. 63-90).—The author gives data and discussions bearing on the relation of grain weight to the Nitrogen content of Goldthorpe barley, and the effect of different factors on this relation, like growing place, time of sowing, thickness of sowing, influence of season, etc.—F. W. WOLL.

Investigation of the quality of upper Bavarian barley grown in 1899, R. ULRICH (*Vrtljschr. Bayer. Landw. Rathes.*, 5 (1900), No. 2, pp. 125-137).—Comparative data as to the physical characteristics, germinative power, color, odor, specific gravity, etc., of barley grown in 20 different districts of Bavaria.

The harvest and sale of barley (*Deut. Landw. Presse*, 27 (1900), No. 55, p. 699).—An abstract is here made of an article on this subject by Remy. From the figures given it is shown that the yellow ripe stage is the earliest condition in which barley should be cut. For brewing purposes, however, it increases in value up to the dead ripe stage.

Some analyses of Norwegian barley, F. H. WERENSKIOLD (*Tidsskr. Norske Landbr.*, 7 (1900), No. 2, pp. 68-74).—Complete analyses of 10 samples of 6-rowed barley and 7 of 2-rowed barley are given, with discussion of their malting qualities and other characteristics. All but 4 of the samples were grown in Norway. In No. 3, pp. 109-114, of the same periodical, the author gives additional analyses of Norwegian barley.—F. W. WOLL.

Tests of commercial fertilizers on maize, A. CARRÉ (*Semaine Agr.*, 20 (1900), No. 999, pp. 218, 219).—In Haute-Garonne nitrate of soda was especially valuable for corn in dry years. In rainy years the nitrate caused an excessive growth of stalk as compared with the grain yield. In such years superphosphate and potash increased the grain yield. A formula containing from 400 to 600 kg. of superphosphate and 200 kg. of nitrate of soda, applied in drills, is recommended for the soils of the district.

Forage crops, J. S. MOORE (*Mississippi Sta. Rpt. 1899, pp. 29, 30*).—Data on the yield of sorghum, velvet beans, and Dwarf Essex rape grown at the station. Sorghum planted in rows 3 ft. apart yielded at the rate of 8.95 tons of field-cured hay per acre; planted broadcast with peas, 5.86 tons per acre; and planted broadcast alone, 4.24 tons per acre. When planted September 15 in rows 3 ft. apart sorghum yielded at the rate of 5.65 tons of hay, containing 10 per cent moisture, 2 months from date of planting.

Analyses of sorghum and forage plants, W. R. PERKINS and E. B. FERRIS (*Mississippi Sta. Rpt. 1899, pp. 39, 40*).—Analyses with reference to the sugar content of 23 samples of sorghum and food analyses of carpet grass; kidney bean; sorghum hay; rape, sun dried; corn and cob, glazed stage; corn fodder; corn tops; prepared feed; velvet-bean hay; Johnson grass hay; peavine hay; cotton seed; cotton-seed meal; wheat shorts; wheat bran; corn-and-cob meal; corn silage; rape, winter grown; and sorghum silage.

Sundry forage crops, J. L. HILLS (*Vermont Sta. Rpt. 1899, p. 308*).—The relative productiveness and composition of 6 nonsaccharine sorghums, soy beans, and 2 vetches grown from seed imported from Russia by this Department are shown in a table. The sorghums tested were not thought adapted to Vermont. The soy bean was considered a promising forage crop. The vetches from imported seed did no better than crops grown from domestic seed.

Forage plants in Washington, W. J. SPILLMAN (*Washington Sta. Bul. 41, pp. 60, map 1, figs. 10*).—Part 1 of this bulletin discusses the climatic divisions of the State, giving notes on the wheat-growing, grazing, and alfalfa sections; and part 2, the leguminous grasses and other forage plants which may be grown in the State, with cultural notes and the results that have been thus far obtained with some of different species at the experiment station. Part 3 classifies Washington farm crops with especial reference to the different sections of the State, and part 4 gives suggestions with regard to the seeding and management of pastures and meadows. A rainfall map of the State concludes the bulletin.

Conversion of arable land to pasture, W. J. MALDEN (*London: Kegan Paul, Trench, Trübner & Co., 1898, pp. 190*).

Lupines and vetches for winter growth (*California Fruit Grower, 25 (1900), No. 638, p. 5*).—Notes on the different varieties of lupines and vetches which have been grown at the State agricultural experiment station and substations, with recommendations as to seeding and directions for obtaining seed.

Varieties of oats compared (*Queensland Agr. Jour., 7 (1900), No. 1, p. 12*).—An account of some experiments with oats conducted by R. P. Wright at the West of Scotland Agricultural College is given. Tam Finlay was the best all-round variety grown, so far as yield of straw was concerned. It tillered best and was the latest variety grown. Tartar King was the earliest variety grown, while Pioneer gave the largest yield of grain.

The selection of potatoes for seed purposes, H. L. BOLLEY (*North Dakota Sta. Rpt. 1899, p. 28*).—The work of testing the value of large and small potatoes from the same vine for seed purposes was continued for the sixth season (E. S. R., 9, p. 942), using 5 varieties of potatoes. The seed tubers used were selected from the preceding year's pedigreed crop.

"The results again affirm those of previous years. A mature bud from one vine thus proved to be as good as any other from the same vine when furnished with the same weight of tuber piece. During six seasons of continuous selection of a small potato from the same vine or strain the work has not tended to 'run out' the crop. The products from this sort of selection seem to have been each year neither better nor worse than those from the line of selection in which the biggest and best tuber was always taken. Soil and cultivation seem to be the main elements in causing a variation in the standard of a potato strain."

Tests of varieties of potatoes in 1898, A. FLÜCKIGER (*Jahresber. Landw. Schule Rütli, 1898-99*, pp. 76-80).—In addition to data as to the yields of 28 varieties, suggestions regarding the handling of seed potatoes are given. It is considered good practice in early spring to place the potatoes in dry sand. This induces a shrinking up of the tubers and prevents sprouting until they are planted. Potatoes thus treated have given from 22 to 30 per cent higher yields.

Wheat straw for potatoes, A. M. HOWELL (*Agr. Gaz. New South Wales, 11 (1900), No. 1, pp. 45-47*).—Discussion of the use and value of straw as a mulch for potatoes.

Fertilizer experiments with potatoes, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 16, pp. 484-487*).—Oil meal was compared with a mixture of oil meal, chlorid of potash, and superphosphate and with complete commercial fertilizers for potatoes on a soil rich in nitrogen but poor in potash and phosphoric acid. The amounts of the fertilizers used in each instance and the yields obtained with 2 varieties of potatoes are tabulated. The profit from the use of the oil meal alone was \$63.11; from the oil meal and mineral fertilizers, \$102.96, and from complete commercial fertilizers, \$283.90 per hectare.

Rice culture in the United States, S. A. KNAPP (*U. S. Dept. Agr., Farmers' Bul. 110, pp. 28*).—This is a popular bulletin based on Bulletin 22 of the Division of Botany of this Department (*E. S. R.*, 12, p. 46). Varieties of rice grown in this country, rice-growing sections, importation and production of rice, rice lands, methods of culture and milling, value as a food, rice by-products, effects of fashion in rice, new wholesale methods of rice production in Louisiana and Texas, prospects of the extension of the rice industry, labor problems, etc., are the principal subjects considered. An impetus of considerable importance has lately been given to the rice industry in this country by the introduction of the Japanese variety of rice Kiushu, which is about 25 per cent more productive than the Honduras variety usually grown, and which possesses superior milling qualities.

On the cultivation and treating of rice in Jamaica, R. H. LINDO (*Jour. Jamaica Agr. Soc., 4 (1900), No. 7, pp. 435-444*).—Complete cultural directions are given, including thrashing, drying, hulling, and preparing for market.

Peculiar frost injuries to rye, FRANK (*Deut. Landw. Presse, 27 (1900), No. 51, p. 653, figs. 2*).—Late frosts in May seriously injured rye. Some plants were entirely killed and others only slightly affected. Plants injured to different degrees, as shown by after growth, are figured and described.

Sugar beets at the experiment station at Capelle, DESPREZ SONS (*Jour. Agr. Prat., 1900, II, No. 31, pp. 160, 161; Semaine Agr., 20 (1900), No. 1002, p. 242*).—The comparative yields per square meter of roots and leaves of sugar beets, percentage sugar content and purity of the juice, etc., are given for 4 experimental plats for each of the years 1896-1900. The beets were harvested July 22 of each year.

Sugar beets, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1899, pp. 146, 147*).—The average weight of beets grown in 1898 was 20 oz.; average sugar content, 13.3 per cent; purity coefficient, 83.1 per cent. From results attained the authors conclude that, though a good grade of beets may be grown in Vermont, yet, owing to the restricted area and short growing season, it will be difficult, if not impossible, to establish the sugar industry in the State.

Sugar beet experiments, E. F. LADD (*North Dakota Sta. Rpt. 1899, pp. 14-17*).—The analyses of 82 samples of sugar beets grown in cooperative experiments with farmers throughout the State are given. They show an average of 12.9 per cent sugar content with a coefficient of purity of 78 per cent. The season was not favorable for best results. See *E. S. R.*, 11, p. 241, for an account of similar work in 1898.

The work of the agricultural experiment stations on tobacco, J. I. SCHULTE and M. WHITNEY (*U. S. Dept. Agr. Rpt. 63, pp. 48*).—A summary is here given of the results obtained in all the experimental work thus far undertaken by the agricultural experiment stations in this country and Canada in the growing, curing, and handling of tobacco; and suggestions given regarding further experimental work.

Cultivation of tobacco, J. M. PRIEGO (*El cultivo del tabaco*. Madrid: M. G. Hernández, 1899, pp. 139, pl. 1. Biblioteca del agricultor, v. 1).

Tobacco, its culture and biology, C. J. KONING (*Leipzig: Wilhelm Engelmann, 1900, pp. 85, figs. 15*).

Growing tobacco under cover (*Tradesman, 43 (1900), No. 11, p. 59*).—Some figures on the growing of tobacco under slat arbors and arbors covered with cheese cloth in Florida are given and methods of overhead irrigation of the tobacco by revolving sprinklers noted.

Tobacco: Methods of culture and manufacture, M. M. GARCIA (*Tabaco: nociones de cultivo y elaboración*. Valencia: Imp. de El correo de Valencia, 1899, pp. 44, pl. 1).

Observations on the growth and products of wheat plants of known selected pedigree, H. L. BOLLEY (*North Dakota Sta. Rpt. 1899, pp. 19, 20*).—This is an account of the comparative yields for 2 seasons of large grains of seed wheat selected from plants grown from large grains and of small grains selected from plants grown from small grains. The yields obtained from the large seed have been the better. The experiment is being continued.

HORTICULTURE.

The fertilizer requirements of asparagus, J. HONIG and E. HASELHOFF (*Braunschweig Landw. Ztg., 68 (1900), Nos. 23, pp. 102, 103; 24, p. 106*).—In addition to the authors' experiments here reported, the works of Paschen, Lierke, and Colomb on the culture and analysis of asparagus are drawn upon. The average weight and composition of asparagus on a hectare are shown to be as follows:

Yield and composition of asparagus.

	Fresh weight.	Dry matter.	Nitrogen.	Phosphoric acid.	Potash.
	Kg.	Per cent.	Kg.	Kg.	Kg.
Asparagus stalks.....	4,000	6.25	250	12,875	4,375
Asparagus berries.....	600	29.00	175	6,000	1,580
Whole plant, without berries.....	9,000	23.00	3,000	47,100	10,770
Total.....				65,975	16,725
					79,460

The fertilizing requirements of a crop of asparagus is thus seen to be about 58.9 lbs. of nitrogen, 15.2 lbs. of phosphoric acid, and 71.77 lbs. of potash per acre. These figures increased or decreased by about one-third give the maximum and minimum limits, respectively, of these elements required by a crop in different seasons. About 18,000 lbs. of cattle manure would supply asparagus with all the essential elements required for a crop grown on one acre. A number of fertilizer formulas containing commercial fertilizer and furnishing nitrogen, phosphoric acid, and potash in about the right proportions for asparagus are given.

The South Haven report for 1899, L. R. TAFT and S. H. FULTON (*Michigan Sta. Bul. 177, pp. 17-56*).—This is a report on tests of varieties of fruits similar in character to those previously reported (E. S. R., 10, p. 49). Some work in spraying, pruning, and fertilizing is briefly noted, and tabular matter given which shows the blooming

and ripening periods, characteristics of the form, color, etc., of 151 varieties of strawberries, 62 raspberries, 29 blackberries, 23 currants, 20 gooseberries, 69 cherries, 49 peaches, 55 pears, 10 quinces, 46 plums, 103 grapes, and 122 apples. Brief notes on a number of varieties of nuts, including almonds, chestnuts, filberts, and walnuts, are also given, together with descriptions of a number of varieties of fruits which have not been described in previous reports of the station.

Following the severe freeze of the winter of 1898, experiments were made in pruning back peach trees which had been more or less injured. The authors summarize the results obtained in this experiment briefly as follows:

"Very severe pruning or removing all the tops down to the stumps of main branches proved dangerous to the life of the trees. More moderate pruning or cutting back on branches from one-half to three-fourths of an inch in diameter gave good results. Trees pruned in the ordinary way were not, at the close of the season, in quite so good condition as those pruned more severely. These results are not considered conclusive."

Early spraying with copper sulphate solution in March proved, under ordinary conditions, an effectual remedy for leaf curl.

Pollination in orchards, S. W. FLETCHER (*New York Cornell Sta. Bul.* 181, pp. 340-364, figs. 23).—This bulletin discusses popularly various reasons why flowers of orchard trees often fail to set fruit, and the general subject of self-sterility of orchard fruits, giving suggestions based on the experience of the author and others as to the planting of mixed orchards so as to overcome these defects.

Vigorous growth of wood, fungus diseases, frost injury, and continuous rain during the blooming season are given as some of the factors which prevent the setting of fruit. "In general the cause of self-sterility is that the pollen of a variety is unable to fertilize the pistils of that same variety." Self-sterility, however, is not a constant character, and some varieties which are self-sterile under certain conditions may be nearly self-fertile under more favorable conditions. Orchard fruits can not be separated into self-sterile and self-fertile varieties. The following list, based on the author's experience and on the reports of over 500 fruit growers, is considered a conservative list of varieties which tend toward self-sterility, and which, therefore, should not be planted alone in large blocks:

"*Pears*.—Angouleme (Duchess), Bartlett, Clapp, Idaho, Kieffer, Nelis. *Apples*.—Bellflower, Primate, Spitzenburg, Willow Twig, Winesap. *Plums*.—Coe Golden Drop, French Prune, Italian Prune, Kelsey, Marianna, Miner, Ogon, Peach, Satsuma, Wild Goose, and, according to Waugh and Kerr, all other varieties of native plums except Robinson. *Peach*.—Susquehanna. *Apricot*.—White Nicholas. *Cherries*.—Napoleon, Belle de Choisy, Reine Hortense. Most of these varieties are self-fertile in some places, but the weight of evidence shows them to be uncertain."

The mutual affinity of certain varieties for cross pollinating each other, the necessity for planting with self-sterile trees, trees which

may serve as pollinizers for them, and the good effects of cross pollination over self-pollination of certain varieties, are discussed at considerable length. The results obtained at the station in self and cross pollinating experiments with a number of varieties of different fruits are shown by the aid of figures. Suggestions are also given regarding the selection, distribution, and planting of trees largely intended as pollinizers in orchards. The advantages of generally mixed plantings is pointed out, and notes are given on pollen distribution by the aid of wind and insects.

Report of the horticulturist, F. A. WAUGH (*Vermont Sta. Rpt. 1899, pp. 189-251, figs. 9*).—The subjects here reported upon are the pollination of plums, types of European plums in America, hybrid plums, geography of variation in the genus *Prunus* in America, and varieties and culture of cherries in Vermont.

Pollination of plums (pp. 189-209, figs. 2).—This subject has been previously reported upon (*E. S. R.*, 11, p. 347). Further work has strengthened the previous conclusions of the author, that for all practical purposes native and Japanese plums may be considered self-sterile, and that in order to insure fecundation of the blossoms varieties in orchards must be mixed. In mixing the varieties for purposes of pollination, the following points should be observed: (1) Blossoming season; (2) mutual affinity; (3) amount of pollen borne, and (4) the value of the pollinizer as a fruit bearer. The time of blossoming each year has been found quite uniform. A map with "isophenal" lines is given showing the blossoming season of Wild Goose in different latitudes for 1899. The mutual affinity of certain well-known varieties as pollinizers for each other is discussed, and a table of varieties given with a list of recommended pollinizers for each. Previous work, which demonstrated that insects are necessary to pollination, has been confirmed. The wind, if of any use in cross fertilizing plums, plays a very subordinate part. A list of insects captured on plum blossoms in Oklahoma, Maryland, Iowa, and Vermont is shown. The honeybee performs by far the greater part of the pollination. The uselessness of spraying while the trees are in blossom is pointed out.

The cause of the phenomenon known as June drop was investigated. Careful examination of the sound and fallen fruit showed this trouble to be due to 3 principal causes: (1) nonpollination; (2) curculio, and (3) the struggle of the fruit on the stem for existence. In the examination of the fallen fruit of 9 different varieties only 41 per cent had been fecundated. Nonfecundated fruit usually falls in June, while the larger amount of the fruit attacked by the curculio falls in July. A large number of fruits often set on a single fruit spur. As only a part of these can develop the weaker are crowded off, even though well fertilized and free from curculio attacks. In combating the June drop the struggle for existence may be left out of consideration.

The question of pollination is also a matter which should be considered when the orchard is set. The curculio is the factor to be guarded against, particularly as this cause may reduce the crop to a total loss.

Types of European plums in America (pp. 210-218).—Both the older and the more modern types of European plums are considered in some detail and a classification given of present day types. The following groups are distinguished: Myrobalan, Damsons, Reine Claude, Dame Aubert, prunes, Perdrigons, Diamond, Bradshaw, and Lombard. Varieties which fall under each group are noted.

Hybrid plums (pp. 218-230, figs. 2).—In this continuation of previous work (E. S. R., 11, p. 47), the question of the hybrid parentage is further discussed, the parentage of 18 known hybrids being given, together with notes of the year on 39 hybrid varieties.

Geography of variation in the genus Prunus in America (pp. 231-239).—This is a discussion of the variation of native American species of Prunus which occurs in different sections of the country, illustrated by 2 maps which show the general trend of the distribution of the several species series. Three points are made the basis of discussion: “(1) the striking parallelism of modification which obtains in the several species series; (2) the relation of this modification to geographical distribution; and (3) the application of a uniform system of nomenclature to the genus which shall exhibit the several groups in their proper relationships and with due perspective.” The Americana, Chickasaw, Hortulana, Maritima, Sand Cherry, Choke Cherry, and Black Cherry series are discussed geographically and characterized; and a systematic summary given of the various series, species, and varieties. The preferred botanical names are noted with principal synonymy. In the preferred names, certain changes are suggested which “seem to help toward putting the nomenclature of the genus Prunus on a more uniform basis and to show more clearly the important natural relations existing between the various members of the several series.” A fact developed in the author’s study is that the Americana series of plums is continuous from New Brunswick to the Mexican border. Characteristic changes occur in the different latitudes, but “there is no break either in the geographical distribution or in the gradual morphological modification of the series.”

Field notes on cherries (pp. 240-251, figs 5).—These notes are based on results obtained with a number of varieties sent out by the station to different parts of the State some years previous. In general only sour cherries succeed in Vermont, more especially those of the Morello class. Descriptive, historical, and nomenclatural notes are given on 18 varieties, followed by general, cultural, and marketing notes. The varieties recommended for use on the ordinary farm, noted in the decreasing order of their desirability, are as follows: Morello, Montmorency, Brusselet Braun, Ragg, Bessarabian, Schatten Amarelle,

Girotte du Nord, and Juneat Amarelle. The author notes that there is a ready and profitable home market in Vermont for 25 times the amount of cherries now grown, and that cherries are easier to grow than potatoes.

Facts and opinions about plums and plum growing in Iowa, J. CRAIG (*Iowa Sta. Bul.* 46, pp. 233-303, figs. 32).—This bulletin sets forth some of the facts obtained in an investigation of the plum industry in Iowa relative to the character, blossoming period, hardiness, popularity, etc., of a large number of varieties grown within the State; presents an epitome of the experiences of many orchardists on plum culture in different parts of the State; describes 118 varieties of plums, and gives directions for planting, cultivating, pruning, spraying, thinning, topgrafting, selection of plum stocks, and the planting of plums with regard to cross pollination.

The relative hardiness of the fruit buds of a large number of varieties of plums grown in different parts of the State was determined by examination of buds sent in to the station in the spring of 1899. The data obtained are tabulated, and are instructive "from the standpoint of exhibiting class characteristics, varietal differences, and effect of locality upon variety."

The characteristics of all the leading types of plums, as shown by their behavior in Iowa, are summarized comparatively in tabular form. From these data the author bases his belief that the chief reliance of Iowa plum growers must be placed upon varieties of the Americana group. The improvement of this group of plums by Iowa horticulturists is pointed out. From circular letters addressed to leading fruit growers, the varieties De Soto, Hawkeye, and Wyant of the Americana group and Minor of the species Hortulana are shown to be the most popular plums grown in Iowa for both market purposes and for home use. The Domestica and Japanese plums are practically uncultivated in Iowa except in the 4 southern tiers of counties. Lombard and Green Gage of the Domestica and Burbank and Abundant of the Japanese are the favorite varieties grown.

The author suggests lists of varieties of plums for planting in each of the 9 tiers of counties of the State. The curculio, gouger, aphid, and rot are mentioned as the most serious enemies of native and Domestica plums. Of the Japanese plums, rot is the enemy of greatest importance.

Fertilizing self-sterile grapes, S. A. BEACH (*New York State Sta. Bul.* 169, pp. 331-371, pls. 2).—Work of the author in testing the self-fertility of grapes has been previously noted (E. S. R., 11, p. 248). The present work reports a study of the question whether some grapes are better than others for fertilizing the self-sterile kinds. The work has been carried out in 3 different sections of the State. Cross pollination was effected by brushing the bunches of the 2 varieties to be cross

pollinated together or by inclosing the variety furnishing pollen with the variety to be pollinated in a paper bag and shaking the 2 together. Paper bags were used in each instance to prevent cross fertilization by foreign pollen.

"Twelve nearly or quite self-sterile varieties were treated with pollen from 1 or more of 24 varieties ranging from perfectly self-fertile to self-sterile. The results are given in the body of the bulletin, both in detail and summarized.

"The use of self-sterile varieties as pollenizers for other self-sterile varieties resulted in failure. Self-sterile varieties fertilized with varieties not strongly self-fertile produced clusters varying in compactness about as did the bunches of the pollinating variety. Self-fertile sorts, with rare exceptions, gave good results when used as fertilizers for either partially self-sterile or completely self-sterile varieties. From study of the effect of pollen from different varieties upon the same self-sterile variety, it seems probable that failure to set fruit may be due to several causes, such as dropping off of blossom buds before they open or poor condition of the vine; but the most common cause is imperfect pollination due to impotent pollen.

"Lists are given of varieties, both strongly self-fertile and imperfectly self-fertile or self-sterile, which blossom very early, medium early, in mid-season, medium late, late, and very late."

Bench grafting resistant vines, F. T. BIOLETTI and A. M. DAL PIAZ (*California Sta. Bul. 127, pp. 38, figs. 10*).—The gradual spread of the phylloxera in California vineyards, necessitating their reestablishment on resistant roots, has led the authors to carry out extensive investigations as to the most suitable varieties for this purpose, the best methods of grafting the same, and the grafting of vinifera varieties upon various resistant stocks. Cuttings imported from France were so damaged during transportation as to make desirable the use of only California-grown cuttings in the experiments.

The 3 most resistant stocks used in 1898 were *Riparia Gloire de Montpellier*, *R. grande glabre*, and *Rupestris St. George*. Twelve vinifera varieties grew well and made good unions on the first, 14 on the second, and 13 on the third. Brief detailed notes on the growth in 1899 of each of these varieties are given, as well as of the growth of some other varieties and of certain crosses of *Rupestris* on its own roots.

In 1899 the experiments consisted chiefly of tests of methods of grafting and of planting in the nursery. Ten varieties of American grapes were used as stocks, the varieties *Zinfandel*, *Mondeuse*, *Tokay*, and *Ferrara* as scions, and 3 varieties for rooting experiments.

The proportion of successful unions obtained by the different methods of grafting and with the different stocks is shown in the following tabular summary.

Tabular review of grafting experiments.

Nature of experiment.	Proportion of unions.		Remarks
	First class.	Second class.	
	<i>Per cent.</i>	<i>Per cent.</i>	
Champin grafts.....	14	11	Unions very complete.
English cleft grafts.....	37	6	
Scions with two eyes.....	16	13	
Scions with one eye.....	38	7	Unions weak.
Grafts callused in sand.....	61	7	
Grafts callused in straw.....	46	12	
Grafts not callused.....	26	13	Growth rather short.
Zinfandel on Rupestris St. George.....	64	11	Good growth.
Mondeuse on Rupestris St. George.....	54	10	Do.
Ferrara on Rupestris St. George.....	75	9	Very strong growth.
Tokay on Rupestris St. George.....	60	6	Strong growth.
Rupestris St. George as stock.....	64	11	Do.
Riparia Gloire de Montpellier as stock.....	15	12	
Herbement.....	0	0	
Lenoir.....	1	2	Good growth.
Cunningham.....	7	4	
American Rulander.....	0	0	
Munson, rooted vines.....	69	0	Good growth.
America, rooted vines.....	0	30	
Champini, rooted vines.....	0	0	
Elvieand, rooted vines.....	0	0	

"The figures in the above table must not be taken as representing the exact relative values of the various methods and varieties compared, but . . . may be considered as valuable indications."

Relative to the influence of the scions on the growth of the grafts, the authors state as follows:

"The Mondeuse, though quite satisfactory, gave a smaller percentage of successful grafts than any of the others. They started later than the Zinfandel, and, though the growth and root system were somewhat stronger, the wood was not quite so well matured. The Zinfandel did very well, giving 64 per cent of good grafts and making good growth. The black Ferrara, however, made almost phenomenal growth and yielded 75 per cent of first-class unions. The growth of the Tokay was almost equal to that of the Ferrara, but the number of successful grafts rather less—60 per cent."

The harmful results following neglect in cutting the raffia or other binding material or not trimming away the roots put out by the scions is illustrated by photographic reproductions of several deformed specimens.

The experiments in rooting 580 cuttings of Rupestris St. George, 40 of Riparia Gloire de Montpellier, and 45 of Solonis resulted in 83 per cent of well-rooted vines in the first instance and 80 in the second. Botanical descriptions are given of these 3 most promising resistant stocks for use in California, and the difference in character of their root systems is illustrated.

Some of the conclusions of the authors relative to the results of the whole work are as follows:

"A cutting graft of suitable varieties makes as large and vigorous growth as a simple cutting, so that by the method of bench grafting no time is lost in establishing a resistant vineyard.

"Resistant varieties which are difficult to root but easy to graft when old, such as Lenoir, should not be bench grafted.

"Care in callusing, planting, and treatment in nursery, and especially in keeping

the grafts moist from the time they are made till they are in the callusing bed, will enable even an inexperienced grafter to obtain at least 60 per cent of good, grafted plants.

"Callusing in sand insures more perfect unions and a larger percentage of successful grafts than planting directly in the nursery.

"The moisture in the callusing bed should not be excessive, and the temperature should be relatively warm.

"The growing grafts should be watched closely in order to see that the roots of the scions are removed before they become large, and that the raffia is cut before it strangles the graft.

"The English cleft graft is preferable to the Champin graft, because it gives more perfect unions and can be made with more accuracy and rapidity.

"Scions of two eyes are preferable to those of one eye, as they give more chances of success.

"Rupestris St. George seems to be remarkably adapted to California soils (except the heaviest clays) and conditions, and is to be preferred to any variety yet tested here wherever deep penetration of roots is possible and desirable.

"All the eyes of the Rupestris stock should be cut out deeply and carefully.

"A vigorous and large-growing vinifera scion promotes an equally vigorous and large growth of Rupestris St. George used as stock."

The forcing of plants by ether, J. FISCHER (*Amer. Gard.*, 21 (1900), Nos. 283, pp. 358-360, figs. 4; 284, pp. 372, 373).—According to the author, the resting period of a plant when growth is almost or entirely discontinued should be distinguished from the "forced inactivity" of a plant which results from surrounding conditions, as extreme cold or lack of moisture, which make growth impossible. The effects of ether vapor in stimulating into early growth and bloom may find a profitable application in the former condition, while in the latter it is without appreciable effect. The resting period of plants is divided into 3 stages—early rest, middle rest, and after rest, corresponding to decrease in growth, complete rest, and increasing activity, respectively. With the lilac the winter buds are said to be in early rest until midsummer, then in middle rest until the end of October. From the end of October until the end of December or first of January they are in the after-rest stage, "when all of the buds emerge from the resting condition and are held in a condition of forced inactivity by the cold season." During the stages of early and middle rest the stimulating influence of ether vapor is very small and practically without value. It is during the stage of after rest that its use is most effective.

According to the author, the treatment with ether must always be given plants which have not lost or are losing their leaves. "In general it is only in the after-resting stage that etherization is of practical value. Exact dates for the earliest forcing of different species can not be given because the differences due to the season, variety, and method of culture are so great. In general it may be said that the ether method makes it possible to force shrubs 3 to 6 weeks earlier than by ordinary methods of culture."

The author's experiments with Tulip La Reine showed a gain in earliness of from 8 to 12 days due to etherization. Etherized tulips

did not hold the blooms so well. Good results were obtained in the open-air forcing of several varieties of lilacs, *Prunus triloba*, and *Viburnum*. "No practical results have been reached in the etherization of bulbs before the formation of the roots. It seems to be dependent upon the fact that these structures, if etherized before the roots are formed, are retarded." The beech was considerably retarded in its development by etherization. After the resting period, etherization seems to have no influence upon the development except perhaps to slightly hinder the growth of the shoots. As to the effect of etherization on the color of the flowers, the author states that with lilacs the color was weaker than in untreated specimens. With an exposure of only 24 hours to the ether, the growth was not so rapid and the color deeper.

"To develop strong colors, the plants [lilacs] should be placed in temperatures of 50 to 54° F. Very beautifully colored flowers have been produced at higher temperatures on Andenken and Louis Späth. . . . Splendidly developed flowers, pure white, on Marly Rouge have been obtained by growing etherized specimens of the plant at 62 to 72° F. in full light. Specimens of the same developed later without etherization but under the same conditions otherwise produced sparing bunches of reddish-gray flowers."

Details are given for constructing apparatus in which plants may be etherized and specific directions given for etherizing lilacs, azaleas, *Viburnum opulus*, Amygdalaceæ, Spiræa, *Pyrus floribunda*, *Staphylea colchica*, *Deutzia gracilis*, lily of the valley, and tulips. The summarized directions of the author regarding etherization of plants are as follows: Use only sulphuric ether. The etherizing apparatus should consist of a chamber lined with tinfoil or made vapor-proof in some other manner, with a vessel in the upper part from which ether may be evaporated. The room temperature should be 62 to 66° F. in the daytime, and may be allowed to drop to 58° F. at night. Plants should be exposed to ether vapor 48 hours altogether; or, exposure 48 hours, ventilation 48 hours, and exposure again for 48 hours. For shrubs the amount used should be 1½ oz. of ether for each 40 gal. of air in the chamber. At the close of the exposure to ether, the plants should be brought into a warm room. Etherized plants require less heat for their development than plants not so treated.

Report of the section of botany and horticulture, C. S. CRANDALL (*Colorado Sta. Rpt. 1899, pp. 32-34*).—A brief report is given of the effect of the severe freeze of the winter of 1898-99 on the plum and apple orchards. Of 152 varieties of plums in the station orchard none escaped injury entirely and 30 were killed, as follows: Chickasaw, 5; Beach plum, 1; Wild Goose, 6; Domestica, 6; Japanese, 7; Americana, 4; Hybrid, 1. Individual trees of 44 varieties produced some bloom, of which 37 were Americanas; 5 belonged to the Miner group; 2 were unclassified hybrids; and 1 was *Prunus besseyi*. The young apple orchard suffered even greater loss than did the plum orchard.

Report of the horticulturist, A. B. MCKAY (*Mississippi Sta. Rpt. 1899, pp. 16-21*).—The station irrigation plant is briefly described and an account given of the small and orchard fruits recently planted at the station, with notes on their care.

Report of the horticulturist, C. B. WALDRON (*North Dakota Sta. Rpt. 1899*, pp. 47-51).—This report reviews in outline the work of the year and notes the varieties of garden vegetables which succeeded best. The white ash, which has been recommended as one of the most promising trees for groves and timber belts in the State, was subject to serious attacks during the year from borers and bark beetles that appeared in such numbers as to destroy or cripple nearly all the trees. It is thought from the present outlook that continued plantings of this tree must be abandoned.

In the fields the Rocky Mountain locust and Hessian fly were the most serious insect pests of the year. Some notes are given regarding their control.

The chayote, E. ANDRÉ (*Rev. Hort.*, 72 (1900), No. 15, pp. 420, 421, pl. 1).—This tropical fruit or vegetable (*Sechium edule*) is illustrated and described and suggestions given regarding its culture and uses.

Cultivation of pepper in Bombay, J. W. WOLLISON (*Agr. Ledger, 1900*, No. 3 (Veg. Prod. ser. No. 48), pp. 23-26).—Methods of growing and harvesting the black pepper of commerce.

The apple and how to grow it, G. B. BRACKETT (*U. S. Dept. Agr., Farmers' Bul. 113*, pp. 32, figs. 10).—This bulletin is intended primarily for "the guidance of the farmer in the propagation, cultivation, and care of the family orchard." Lists of varieties of apples suitable for culture in different sections of the country are given, and these lists include many commercial varieties suitable for the same districts. Utilization of orchard fruits and the gathering and disposing of the crop are also discussed.

Apples in North Carolina (*Bul. North Carolina State Bd. Agr.*, 21 (1900), No. 7, pp. 40, pls. 4, figs. 19).—Popular directions for the culture of apples in North Carolina, with suggestions regarding the most suitable varieties for different purposes and descriptions of some 60 varieties. Papers on the advancement of apple culture in the western part of the State, on the care in handling winter apples, preparing apples for the market, and on the diseases and insects affecting apple trees in North Carolina form the concluding portion of the bulletin.

The apples of France; planting and cultivation, manufacture of cider and apple brandy, fruit production, E. GAUTIER (*Les pommiers de France; plantations et cultures, fabrication du cidre et des eaux-de vie de cidre, production fruitière. Paris: E. Brocherioux, 1899*, pp. 87, pl. 1, figs. 10).

Orchard technique: III. Growing the apple orchard, W. B. ALWOOD (*Virginia Sta. Bul. 99*, pp. 53-79, figs. 12).—Detailed popular directions for laying out the orchard, selecting nursery stock, planting trees, pruning, cultivating, etc.

Time of pruning affecting time of ripening apricots, J. W. MILLS (*Pacific Rural Press*, 60 (1900), No. 5, p. 69).—The author pruned experimentally 12 varieties of apricots. One-half of each variety was pruned in July after the fruit was taken off and the other half late in December. The late pruning considerably retarded the ripening period of the apricots, the last picking of the July-pruned trees being taken off before the first picking of the December-pruned trees was ripe. This prolonging of the picking season is considered an important factor in securing the crop without loss.

Varieties of sour cherries, U. P. HEDRICK (*Utah Sta. Bul. 64*, pp. 43-49, fig. 1).—The author discusses the possibility and profits of sour-cherry culture in Utah and describes 23 varieties growing at the station. A table is given showing the yields in pounds and marketing period of the same varieties for the 2 years 1898 and 1899. Small plantings of sour cherries throughout the State are urged. Brusseler Braune, Carnation, Osteheim, and Sklanka are among the best varieties growing at the station.

Cherries in the West (*Amer. Gard.*, 21 (1900), No. 293, p. 520).—From remarks made at the Nurseryman's Association it would seem that the Early Richmond, Dye-house, and Montmorency were the most satisfactory varieties to grow in the West.

Cultivation of citrus fruits, E. ARNO (*La coltivazione degli agrumi. Palermo: Alberto Reber, 1899*, pp. 447, figs. 36).—The botany of citrus fruits, chemical analysis of constituent parts, favorable topographic and climatic conditions for growth, cul-

ture, fertilizing, injurious pests, and the economy in growing citrus fruits are discussed.

Fruit culture in Queensland—citrus culture, A. H. BENSON (*Queensland Agr. Jour.*, 7 (1900), No. 1, pp. 34-39).—Popular directions regarding the cultivation and manuring of citrus trees and on handling and packing the fruit.

Citrus regions of California, B. M. LELONG (*Pacific Rural Press*, 60 (1900), No. 6, p. 84).—A popular discussion of the orange and lemon lands and the conditions of their culture.

Culture of the date palm (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 12, pp. 742-744).—From investigations by the Cape Colony Department of Agriculture it seems that a considerable number of these trees are now growing in Damaraland and Namaqualand and the fruit forms no inconsiderable proportion of the food of the poorer classes. In Damaraland the date palm is successfully cultivated at elevations of 3,000 to 3,500 ft. Above this height it is uncertain. Some information as to the culture and habits of the date palm is included in the article.

Coffee culture in Queensland, H. NEWPORT (*Queensland Agr. Jour.*, 7 (1900), No. 1, pp. 45-50, pls. 4).—Pulping and curing are the operations considered. Buildings and machinery for these operations and details of manipulation are given.

Coffee and india-rubber culture in Mexico, preceded by geographical and statistical notes on Mexico, M. ROMERO (*New York: G. P. Putnam's Sons*, 1898, pp. 417).

Strawberries, C. S. CRANDALL and C. H. POTTER (*Colorado Sta. Bul.* 53, pp. 27).—Detailed popular directions for the culture, fertilizing, irrigation, selection, and pollinating of strawberries, with descriptive notes on 74 varieties and a table showing the comparative size, vigor, productiveness, etc., of the different varieties.

Strawberry trials (*Amer. Gard.*, 21 (1900), No. 290, p. 469, fig. 1).—A report is here given on the test of varieties of strawberries grown at the trial grounds of *American Gardening* in 1900. Some 18 of the better varieties are noted in detail.

Food for strawberries, A. H. WARD (*Amer. Gard.*, 21 (1900), No. 294, p. 535).—Manuring strawberries is considered. Rotten leaves, decayed wood, and fermented peat ash in small quantities mixed with other vegetable substances are thought to make a better compost for strawberries than animal manures. Nitrate of soda and powdered phosphate of lime are also recommended, about 400 lbs. of the mixture per acre being used.

Strawberry breeding, N. O. BOOTH (*Amer. Gard.*, 21 (1900), No. 294, pp. 534, 535).—Methods of breeding strawberries are given and the objects to be sought noted. Some results secured at the Missouri and New York State experiment stations in breeding strawberries are given. Usually less than 1 desirable seedling can be expected out of each 1,000 seedlings grown. In Missouri the varieties Warfield No. 2, Lady Rusk, Crescent, and Bubach No. 5 gave seedlings about 5 per cent of which were considered worth saving beyond the first fruiting year. Crescent \times Sharpless has given a high percentage of good seedlings both in Missouri and New York.

The Oregon evergreen blackberry, U. P. HEDRICK (*Utah Sta. Bul.* 64, pp. 50-54, fig. 1).—Notes on the yields and characteristics of the Oregon evergreen blackberry, with replies to letters of inquiry of 8 nurserymen regarding its origin, history, qualities, cultivation, possibilities, etc.

Grapes for calcareous soils, F. LAVOUX (*Messenger Agr.*, 5. ser., 1 (1900), No. 5, pp. 187-191).—As a result of tests on the experimental grounds at Charentes, lists of varieties suitable for growing on light, dry, humid, and heavy soils, containing various amounts of lime, are given.

Observations on the phenology and maturity of cultivated vines, BONNET and VIDAL (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 329-359).—The phenology and date of maturity of about 500 varieties of cultivated grapes growing at the National Agricultural School grounds at Montpellier are recorded for the sea-

son of 1899. A difference of 34 days was observed between the earliest and latest varieties starting into growth, when all varieties were considered. With French varieties alone a difference of 22 days was observed.

What grapes are best as pollenizers, F. H. HALL and S. A. BEACH (*New York State Sta. Bul.* 169, popular ed., pp. 5).—This is a popular edition of Bulletin 169 of the station (see p. 240).

Systems of grape pruning in the Mediterranean region, L. RAVAZ (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 315-328).—After considering comparatively and physiologically a number of different systems of grape pruning, the author believes that with the vines, soils, and climate of the Mediterranean region the older method of short pruning on low stocks is to be preferred to later methods of long pruning, since more wine of a better quality is obtained.

On the quantity and quality of the products of the vine, L. RAVAZ (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 329-333).—Theoretical considerations on increasing the quantity while maintaining the quality of vine products.

The growing of herbaceous Calceolaris, W. KLEINHEINZ (*Amer. Gard.*, 21 (1900), No. 289, pp. 455, 456, fig. 1).—Cultural directions.

The clematis (*Amer. Gard.*, 21 (1900), No. 293, p. 521).—Historical and cultural notes, with remarks on hybridizing and on diseases and insects.

How to grow lilies, J. MCGREGOR (*Amer. Gard.*, 21 (1900), No. 292, p. 504).—Short paper covering time of potting the bulbs, removal to the house, temperature, etc., read by the author before the Pennsylvania Horticultural Society.

The history of the rose (*Jour. Hort.*, 52 (1900), Nos. 2697, p. 478; 2702, p. 34; 2706, p. 132).—The early history is dealt with especially.

Chronological contributions to the history of the sweet pea (*Amer. Gard.*, 21 (1900), No. 292, p. 501).—Historical notes on the sweet pea, beginning with its introduction into England from Italy in 1696 and coming up to the present.

Nicholson's dictionary of gardening. Supplement, G. NICHOLSON (*Hyde Park, Mass.: G. T. King*, 1900, pp. 376, figs. 385).—This work supplements the author's dictionary of gardening, bringing the matter up to date as far the letters A-F.

FORESTRY.

The density of forest crops, W. SCHLICH (*Gard. Chron.*, 3. ser., 27 (1900), No. 705, pp. 414-416).—The author undertakes to answer the question as to the proper density of forest crops at which the fertility of the soil is preserved, if not increased, and the most valuable class of timber produced. The results of thousands of measurements are given of Norway spruce, beech, oak, and Scotch pine, in which all kinds of soils are considered. The average results are given in the following table:

Density of forest crops.

Age of wood.	Number of trees to the acre.			
	Norway spruce.	Beech.	Oak.	Scotch pine.
20 years	2,800	2,800	2,700	1,900
30 years	2,000	1,790	1,140	1,250
40 years	1,380	1,150	640	850
50 years	1,020	770	420	620
60 years	660	560	310	460
70 years	490	440	240	360
80 years	400	330	200	290
90 years	330	260	160	240
100 years	290	220	140	200
110 years	260	190	120	180
120 years	250	160	105	160

Experiments in forestry, C. S. CRANDALL (*Colorado Sta. Rpt. 1899*, pp. 34, 35).—The station has continued experiments in forestry started in cooperation with the Division of Forestry of this Department in 1896. On one of the forest plats nearly 4,000 plants of southernwood (*Artemisia abrotanum*) were planted as nurse plants for conifers. The plants are said to have covered the ground completely and to serve well as a protection for other plants, but to be of no other use, as they kill to the ground each winter.

Some local conditions of forestry in England (*Jour. Bd. Agr. [London]*, 7 (1900), No. 1, pp. 1-9).—Notes are given on the distribution and growth in England and Wales of a number of the more common forest trees, the diseases and injuries to which they are subject, and market conditions.

Report of the Bureau of Forestry, T. SOUTHWORTH (*Rpt. Clerk Forestry, Ontario, 1899*, pp. 144, pls. 8).—Notes are given on forestry methods, forest reserves, wind-breaks, shelter plantings, street tree planting, etc. A compilation and history is given of the Crown timber regulations to the present time.

Forest law in the United States, T. CLEVELAND, JR. (*Forester*, 6 (1900), No. 7, pp. 153-160).—The topics discussed in this paper are: Forest law in general, early settlers and the forests, beginnings of a Federal forest policy, the Federal land policy, and timber culture laws.

Railroad forestry, J. H. SUTOR (*Sci. Amer. Sup.*, 50 (1900), No. 1286, pp. 20619, 20620).—An address delivered before the Central Association of Railroad Officers in which reforestation is strenuously urged.

Notes on the forest trees of Ohio, W. R. LAZENBY (*Jour. Columbus Hort. Soc.*, 15 (1900), No. 1, pp. 26-29, pls. 3).—Notes are given on the forest trees which are found growing wild in the State of Ohio. The number is said to be at least 112 species, representing 25 orders and about 50 genera.

Observations on the Eucalyptus of New South Wales, V and VI, H. DEANE and J. H. MAIDEN (*Proc. Linn. Soc. New South Wales, 1899*, Nos. 3, pp. 448-471, pls. 6; 4, pp. 612-630, pls. 3).—Descriptions are given of a number of species and varieties of Eucalyptus. Notes are also given on their economic value.

The lebbek or siris tree, D. G. FAIRCHILD (*U. S. Dept. Agr., Division of Botany Circ. 23*, pp. 4, figs. 2).—A history and description of this tree imported from India and as found in Egypt. It grows rapidly in the latter country in a sandy soil with little moisture. The wood is durable, works well, and is of value. It is mainly desirable as a shade tree for avenues and is recommended for southern California, Arizona, and Florida.

SEEDS—WEEDS.

Investigations on weeds, H. L. BOLLEY (*North Dakota Sta. Rpt. 1899*, pp. 25-28).—A brief report is given of experiments conducted in weed destruction, in which marked success was obtained when copper sulphate was sprayed over the field at the rate of 1 lb. of copper sulphate to 4 gal. of water, the solution being used at the rate of 40 to 50 gal. per acre.

The author has begun an investigation of weed seeds planted at different depths, in which the seeds of a number of the more common weeds were planted at depths varying from 1 to 10 in.

Studies have been made at various elevators and mills throughout the State to determine what influence they may have as weed distributors. It was found that the following weed seeds occur quite abundantly in wheat and are responsible for considerable loss not only in

the reduction of yield, but in depreciation of the quality: *Ambrosia trifida*, *Lychnis githago*, *Saponaria vaccaria*, *Polygonum convolvulus*, *Setaria viridis*, *S. glauca*, and *Avena fatua*.

Killing weeds with chemicals, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt. 1899, pp. 182-188*).—Since the publication of the bulletin on the use of salt in killing the hawkweed (E. S. R., 8, p. 987), the authors have received many inquiries as to the possibility of destroying other weeds by chemicals, which led them to make a comparative test of a number of chemicals for this purpose. Among those included were common salt, copper sulphate, potassium sulphid, kerosene, arseniate of soda, a mixture of white arsenic and sal soda, and 2 proprietary articles. These chemicals were tested by marking off areas on gravelly walks, roadways, tennis courts, and similar dry, beaten soils. Applications were begun about July 1 and observations continued until autumn. The different chemicals were tried at the rate of about 8 gal. of solution to each square rod of surface. The weeds most commonly present were knotweed (*Polygonum aviculare*), white clover, various grasses, purslane, plantain, dandelion, etc. Of these the knotweed was most troublesome and the efficiency of the chemicals in destroying this weed was considered the best gauge of its value. The experiments with different chemicals are reported at some length, together with notes on their cost, and the following conclusions were drawn:

“Gravel walks, drives, tennis courts, and similar places can be kept free from weeds by the use of certain chemicals.

“Common salt can be used for this purpose, but very heavy applications are required, and when used in such amounts it is liable to be washed into the borders of adjacent lawns. Salt should always be applied in the dry form. The weeds may be more fully suppressed without such danger from washing by certain other chemicals. These are to be applied in solutions, and at the rate of about 8 gal. to the square rod.

“Crude carbolic acid is a very powerful and quick acting herbicide. One pint in 4 gal. of water is usually sufficient; cost as diluted, $\frac{1}{2}$ ct. for a gallon, 4 cts. to the square rod. Its effects are not as enduring, however, as are those of the arsenical solutions.

“Various arsenical compounds are available, including arseniate of soda, a mixture of white arsenic and sal soda, and two proprietary articles. The choice between these latter becomes largely a matter of relative expense and convenience. In general, the choice should, in our judgment, lie between the crude carbolic acid and the arseniate of soda.

“One or at most two applications each season of one or another of these chemicals will, it is believed, suffice to keep down the weeds.”

The use of solutions of sulphate of ammonia and superphosphate for destroying weeds, MAIZIÈRES (*L'Engrais, 14 (1899), No. 36, pp. 851, 852*).—The author quotes from a report of experiments made by M. Georges Castel-Delétréz in eradicating weeds by spraying with solutions of sulphate of ammonia. A 3 per cent solution burnt

the edges of the leaves of plumeless thistles (*Carduus*), but did not appear permanently to injure the plant. A 5 per cent solution destroyed some whole leaves and checked growth for several days. A 10 per cent solution entirely destroyed young plants. A 15 per cent solution applied to plants 20 to 30 cm. in height entirely destroyed a part of them. In experiments with white mustard, a 10 per cent solution completely destroyed the plants in those cases in which application was made before the flower buds were developed. If applied later, it was not effective.

The author then proceeds to report very briefly on some experiments made by himself along this line, using, however, in this case a solution of superphosphate. Details of the experiments are not given, but it is said that very satisfactory results were reached in experiments with various cruciferous plants. The experiments were repeated with mixed solutions of superphosphate and sulphate of ammonia, and in this case a solution of 5 degrees of density proved very efficient. The experiments are to be continued.

Results of experiments on the spraying of charlock, P. H. FOULKES (*Jour. Reading Col., England, Sup. 9, pp. 55-59*).—Spraying experiments were conducted in 6 localities, in which copper sulphate in strengths of 2 to 6 per cent and quantities of 25 to 75 gal. per acre was tested. The applications were made under different climatic conditions on wheat, barley, and oats at different stages of growth, when the charlock plants were quite young, just before flowering, and while in flower. On the whole, the experiments were considered to establish the value of copper sulphate as a means of destruction of charlock. For the best effect of spraying the author considers the following conditions necessary: A clear, still, dry day, the application of a 2 per cent solution at the rate of 50 gal. per acre before the charlock comes into flower, and the thorough application of the spray, in which the nozzle should be held low so that the spray may fall upon and not be driven against the plants. If these conditions are complied with, it is thought that one spraying will be sufficient to destroy the weeds. If rain falls within 24 hours after the spraying, it is advised that the application be repeated.

Spraying of charlock (*Jour. Bd. Agr. [London], 7 (1900), No. 1, pp. 43-45*).—A brief report is given of experiments conducted in north Wales in regions which are notably infested with this weed, in which one-eighth-acre plats were sprayed with copper sulphate, and comparisons made with other plats sprayed with iron sulphate. Iron sulphate failed to produce any appreciable effect upon the weeds, while copper sulphate gave better results although not altogether satisfactory ones. The sprayings were probably made too late in the season, as the results seem to indicate that the advantage of spraying depends largely on the age of the charlock at the time of spraying. No injury to the

crop sprayed was noted. In one series of experiments the plant proved to be the "smooth-leaved charlock," and upon this the solutions seemed to have no effect.

Eradication of moss in pastures (*Jour. Bd. Agr. [London]*, 7 (1900), No. 1, pp. 39, 40).—An account is given of a number of experiments for the eradication of moss in pasture lands. None of the usual reasons assigned for the presence of moss, such as sourness of soil, deficient aeration, or great poverty of the soil were present, the experiments being conducted on light loamy soils which rested on chalk. Chemical and mechanical means were investigated. The chemicals used were sulphuric acid, lime, superphosphate, basic slag, salt, and iron sulphate. The mechanical methods tested were lifting the turf, rolling, and raking. The chemical treatment seemed to have little or no effect, while of the mechanical processes rolling was most effective.

The farmer's interest in good seed, A. J. PIETERS (*U. S. Dept. Agr., Farmers' Bul.* 111, pp. 24, figs. 7).—A popular bulletin on the value of seed testing, in which the relationship between quality of seed and amount sown, methods of seed testing, etc., are described. The results of tests with a number of samples of red clover, redtop, Kentucky blue grass, timothy, orchard grass, smooth brome grass, and crimson clover are given, in which the market price and actual value of seed are shown. In many instances the actual value of the seed, as shown by tests, was decidedly less than the market price paid.

Red clover seed, A. J. PIETERS (*U. S. Dept. Agr., Division of Botany Circ.* 24, pp. 5, figs. 2).—Red clover seed is described, together with a number of its more common adulterants and impurities. The value of testing seed is pointed out and in general it is found that high-grade medium-priced samples are in reality the cheapest.

The seed of smooth brome grass, A. J. PIETERS (*U. S. Dept. Agr., Division of Botany Circ.* 25, pp. 5, fig. 1).—The rapid introduction of this grass in the arid and semi-arid regions of this country has led to many inquiries concerning it, and the author describes popularly the seed and some of the impurities associated with it. Directions are given for sampling and testing brome-grass seed, and the offer is made by the Department to test such seed for those desiring it.

Resistance of seeds to heat, SCHRIBAUX ET AL. (*Messenger Agr.*, 5. ser., 1 (1900), No. 6, pp. 227, 228).—All cereals except maize are said to readily withstand temperatures of 100° C. for short periods. Wheat heated for 1 hour to 105° C. germinated 97 per cent; 115°, 95 per cent; 116°, 93 per cent; 120°, 56 per cent; and 125°, 4 per cent.

The resistance of seeds to high temperatures, V. ROGER (*Messenger Agr.*, 5. ser., 1 (1900), No. 5, pp. 191, 192).—Peas and cress heated to 60° C. for 24 hours and then to 98° for 10 hours gave 30 and 60 per cent germinations, respectively. Heated directly to 98° all were killed. Cress seed germinated after 800 hours in a thermostat at 65° C. Peas and cress in sealed tubes with quicklime retained their power of germination after an exposure of 206 days at 40° C.

Method for determining the relative value of beet seed, G. LINHART (*Kisérlet. Köszlem.*, 3 (1900), No. 2, pp. 136-139).

Annual report of Danish seed control station, 1896-97, O. ROSTRUP (*Tidsskr. Landbr. Planteavl*, 5 (1899), pp. 1-38).—The report gives the usual account of the results of seed analyses made during the year, with summary tables for the years 1887-1897, inclusive, and such other discussions as the work during the year has suggested. There were received for examination during 1896-97 1,762 seed samples,

of which 1,184 were subjected to complete analyses, 243 to determinations of purity, and 310 to determinations of germination. Of the samples 934 were sent by seedsmen, 69 by seed growers, and 508 by farmers, the rest being secured for original investigations. An investigation as to the influence of concentrated sulphuric acid on hard seeds of legumes showed that the germination of flat pea was greatly improved by steeping the seeds in acid for one minute; after 60 days the germination of the treated seed was 84 per cent, and that of the untreated seed 28 per cent. After 300 days all the treated seed had germinated, while those not treated showed a germination of 76 per cent. It is likely that a longer treatment with sulphuric acid will further improve the germination of flat pea. A sample of red-clover seed left in concentrated sulphuric acid for 24 hours still contained 9 per cent of viable seed.—F. W. WOLL.

Report of the Danish seed control station, 1897-98, O. ROSTRUP (*Tidsskr. Landbr. Plantearb.*, 6 (1900), pp. 1-37).

Report of the Danish seed control station for the year 1898-99, O. ROSTRUP (*Tidsskr. Landbr. Plantearb.*, 6 (1900), pp. 113-169).—Contains the usual compilation of the results of seed analyses made during the year, and during the decennium 1889-1899. Of other subjects treated in the report may be mentioned: List of seeds of wild or cultivated plants found in seed samples of cultivated plants sent to the Danish seed control station (pp. 135-154); on the decrease in viability of seeds from spring to fall (pp. 156-158); germination trials of seeds of wild plants (pp. 158-169); germination trials with cacti (p. 169).—F. W. WOLL.

Twenty-seventh report of Markfrökontoret (seed office) (*Copenhagen, 1899, pp. 32*).—The report contains the usual account of the work of the office, and a number of papers on the culture of different agricultural crops.

Reports of Swedish seed control stations for 1898 (*Meddel. K. Landthr. Säll., 1900, No. 63, pp. 401-465*).—Eighteen stations, in part supported by Government, were maintained during the year; 8,258 seed samples were examined at these stations during 1898, 6,147 complete analyses having been made, and 2,111 partial analyses. Farmers sent in 3,161 samples, seedsmen 4,455 samples, and 638 samples were secured by the stations themselves in special investigations; 19.6, 12.2, and 11.6 per cent of the samples received for examination were analyzed at the seed control stations at Lund, Stockholm, and Örebro, respectively. The average results of the analyses for each kind of seed and for each station, with ranges of results, are given in the report.—F. W. WOLL.

Report of the seed control station at Lund, Sweden, for 1899, B. JÖNSSON (*Malmö, 1900, pp. 26*).

Report of the seed control station at Gothenburg, Sweden, for 1898-99 J. E. ALÉN (*Göteborg, 1900, pp. 14*).

Report of the Skara seed control station for 1898-99, S. HAMMAR (*Ber. Verks. Skara Kem. Sta. och Frökontrollanst., 1899, pp. 25-31*).—A report is given of the analyses of 149 lots of seed which were tested between July 1, 1898, and June 30, 1899. Of these rye, red clover, alsike clover, and timothy seed constituted 75 per cent of the samples.

Some common Ontario weeds, F. C. HARRISON (*Ontario Dept. Agr., Toronto, 1900, pp. 80, figs. 34*).—A popular discussion is given on the introduction and spread of weeds; methods of identification, classification, and eradication. The more common weeds of Ontario to the number of 34 species are figured, popularly described, and suggestions given for their eradication. Based upon replies from correspondents, the author represents graphically the comparative destructiveness of Ontario weeds. Those most troublesome in order of destructiveness are Canada thistle, mustard or charlock, wild oat, couch grass, ragweed, oxeye daisy, false flax, dock, burdock, and foxtail.

Noxious weeds (*Rpt. Dept. Agr. Northwest Territories, 1899, pp. 29-40*).—A report is given of the distribution of a number of troublesome weeds and the activity of the inspectors in enforcing the laws on weed destruction.

On the geographical distribution of some of our weeds, J. HOLMBOE (*Tidsskr. Norske Landbr.*, 7 (1900), No. 4, pp. 155-171).

Experiments in weed prevention, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), No. 41, pp. 110-115, fig. 1).—In this pot experiment, 4 series were used: 1, control; 2, sprayed with ammonia liquor from gas works; 3, treated with salt at the rate of 5 cwt. per acre and subsequently sprayed with a 2 per cent solution of sulphate of copper; 4, sprayed with carbolic acid solution. The weeds that appeared were speedwell, groundsel, shepherd's purse, goose foot, and knot grass (*Polygonum aviculare*). Gas liquor used in its full strength, containing 2.93 per cent ammonia, killed all the weeds except goose foot and knot grass. The other chemicals used were found to be practically useless for weed prevention.

Spraying for weed destruction (*Deut. Landw. Presse*, 27 (1900), No. 53, p. 679).—Notes are given on the successful spraying with solutions of iron sulphate for the destruction of field mustard in a number of crops.

Bur medic (*Queensland Agr. Jour.*, 6 (1900), No. 3, p. 209, pl. 1).—Notes are given on *Medicago denticulata* which is considered a very troublesome and injurious weed in pastures.

Destruction of charlock (*Jour. Bd. Agr. [London]*, 6 (1900), No. 4, pp. 465-468).—Good results will, as a rule, be obtained by spraying charlock when not over 3 in. high with a 4 per cent solution of copper sulphate or a 15 per cent solution of iron sulphate at the rate of 40 gal. per acre. Cloudy days without rain give better results than when spraying is done upon bright days.

The eradication of the prickly pear (*Queensland Agr. Jour.*, 6 (1900), No. 4, pp. 319, 320, pls. 2).—An account is given of the successful use of a spraying solution for the destruction of the prickly pear. The composition of the solution is not given.

DISEASES OF PLANTS.

Report of the botanists, G. E. STONE and R. E. SMITH (*Massachusetts Hatch Sta. Rpt. 1899, pp. 56-73*).—The principal investigations of the authors during the season covered by this report have been confined to problems in vegetable physiology and pathology. The presence of a serious disease in asters is reported, and the authors have begun investigations with a view to ascertain the nature of the trouble and the means for its prevention. Bacterial cucumber wilt has made its appearance in the vicinity and caused serious injury to the crop. In the Annual Report of the station for 1897 (E. S. R., 10, p. 648), the authors described a leaf spot of geranium which was thought to be caused by bacteria. At that time it was believed to be the result of abnormal conditions rather than a true disease. However, during the season covered by the report, the disease has been prevalent and has caused a considerable loss. It causes small yellow dull spots in the leaves, so that they soon fall off and the plant becomes nearly denuded. Examination of the dead spots shows they are full of bacteria, but all attempts to isolate the organism have been without success.

Failures of the muskmelon crop are reported due to *Alternaria* sp.

and the common anthracnose (*Colletotrichum lagenarium*). The first disease appeared earlier than before, and spraying experiments for its prevention were too late to be of value. In the case of the anthracnose, applications of Bordeaux mixture begun July 1 or earlier will prevent injury. The maple-leaf blight (*Phyllosticta acericola*), is briefly described. This disease produces large dead spots in the leaves, which become curled and distorted, losing their beauty; but beyond this the actual injury to the tree is considered in most cases slight.

The chrysanthemum rust, which was first reported in 1897 (E. S. R., 10, p. 648), appears to be on the decline. It has appeared in numerous places, but apparently caused little or no damage.

Experiments are reported on growing violets in sterilized soil, the purpose of which was to determine the relation between the production of flowers and the occurrence of leaf spots in sterilized and unsterilized soils. The methods of sterilizing the soil were previously given (E. S. R., 10, p. 1055). The plants for the experiments were made from cuttings started in sterilized sand, afterwards transplanted into sterilized soil and removed out of doors, where they remained during the summer. In the fall they were transplanted into a bed divided into 2 sections, one of which was sterilized and the other not. The yield of flowers from both plats is tabulated, from which it appears there was a gain of 36 per cent in the number of flowers gathered from the sterilized plat over that from the unsterilized one. The observations made to determine the relative amount of leaf spot on the 2 plats showed that the sterilized plats gave the smallest number, indicating the more vigorous plants were grown on the sterilized soil. The authors state that "while there is no doubt as to the beneficial results obtained by sterilizing the same soil for 2 or 3 crops, it does not necessarily follow that the soil will repeatedly stand this treatment and give good crops."

Report on various cryptogamic diseases, E. MARCHAL (*Bul. Agr. [Brussels]*, 16 (1900), No. 1, pp. 8-21, figs. 8).—Brief notes are given on a number of diseases of more or less economic importance. Among those described are the white rust of purslane due to *Cystopus portulacæ*; rusts of cereals, in which *Puccinia graminis* is reported on barley, wheat, rye, oats, and numerous grasses, *P. rubigo-vera* on wheat and barley, and *P. coronata* on oats as well as on certain pasture grasses; the vesicular rust of pine needles caused by *Colcosporium senecionis*; stem rust of rye caused by *Urocystis occulta*; Polyporus on fruit trees, the species mentioned being *P. igniarius fulvus*; a rust of pine needles caused by *Lophodermium pinastri*; a browning of spruce needles caused by *L. macrosporum*; a blight of shallots due to *Sclerotinia fuckeliana*; a new Phoma disease of tomatoes, in which serious injury to the fruit is reported in greenhouses; a leaf disease

of the sycamore caused by *Glæosporium nervisequum*; and a new disease of medlars caused by *Monilia linhartiana*. The disease of medlars is characterized by the appearance of dark brown dry spots along the midrib and principal veins of the leaves. These increase in size until the entire leaf is invaded. The young fruits are also attacked, turn brown, dry, and fall from the tree.

Smut of cereals, H. L. BOLLEY (*North Dakota Sta. Rpt. 1899, pp. 20-25, fig. 1*).—Since 1895 the author has been investigating the influence of different dates of seeding, soil condition, climate, etc., on the growth of smuts, and in the case of the stinking smut of wheat has drawn the following conclusions: The stinking smut of wheat in the region of the station will grow best if left exposed to the weather in the unbroken smut balls throughout the winter months. For best germination of the spores a condition of soil atmosphere approaching saturation is required, while the presence of actual water in the soil is detrimental. A wide range of temperature for the germination of spores has been observed when the soil conditions are favorable. The best soil conditions for a high percentage of infection in the field would be those which give a good growth of the wheat plant, associated with a saturated soil and a daily temperature showing a minimum of 15 to 35° F. In conducting his test it was found that the millet smut developed best when the ground was too wet to produce a large growth of wheat smut, and it is thought probable that each species of smut will be found to vary in the conditions required for its development.

The use of formaldehyde for grain disinfection has been further investigated with good results. Acting upon the popular belief that chlorid of lime would prove beneficial in preventing smuts of wheat, the author investigated the subject, but found it was without value as a smut preventive.

Potato diseases and their remedies, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt. 1899, pp. 151-155*).—This report gives an account of observations and experiments made on potato diseases and their control in 1898. The season was somewhat less favorable for the diseases than the preceding one, the principal injury being reported from tip burn, which occurred rather abundantly on potatoes planted in light soils. Plants sprayed with Bordeaux mixture were relatively exempt from attacks of the flea-beetle and showed little evidence of tip burn. In the vicinity of the station there was little injury due to either the early or late blight, although some damage was reported from these causes in other parts of the State.

Spraying experiments were conducted to test the value of standard Bordeaux mixture in which the lime and copper sulphate were each diluted to the proper degree before mixing, an improperly made Bordeaux mixture in which the concentrated solutions were combined and then diluted to the proper strength, and a commercial Bordeaux mix-

ture which is essentially the same as the second mixture just described. The results obtained from a series of 20 plats showing the comparative value of the different forms of Bordeaux mixture were decidedly in favor of the standard mixture. Tests were also made of 2 commercial powders, Bug Death and Laurel Green, as substitutes for Paris green and Bordeaux mixture for use upon potatoes. The primary object was to determine whether these compounds had any value as fungicides, but the absence of all fungi rendered this portion of the experiment of no value. It was found that both the powders possessed considerable value as insecticides, although no comparison can be drawn with Paris green on account of the difference in the experiments.

A new phoma disease of swedes, M. C. POTTER (*Jour. Bd. Agr. [London]*, 6 (1900), No. 4, pp. 448-450, pl. 1, figs. 5).—A description is given of a somewhat common disease of swedes which occurs in the north of England and, according to the author, appears to have been thus far undescribed. When fairly advanced the disease is usually recognized by pale, straw-colored, or brownish patches which contrast strongly with the ordinary color of the root, and by the large dry cracks which sometimes penetrate deeply into the flesh. The natural color of the swede is destroyed and replaced by discolored patches which are surrounded by a narrow border of dark metallic green, shading into a dark purple. Numerous small spots of a deep purplish green color, encircling a central lighter spot, indicates the commencement of the disease. One striking characteristic of the disease is the dry condition of the attacked cells, the cortex usually separating as a dry papery layer. The microscopical appearances of the fungus are described at considerable length and results of cultures are given in which the complete cycle of the fungus was carried out upon swedes. In general appearance the fungus agrees very closely with the description given of *Phoma brassicae*, which is said to attack cabbages in the west of France. It possesses other characters which have been given for *P. sanguinolenta*, which is said to attack carrots, and the author thinks eventually these different parasites will be found to be forms of the same species.

Suggestions are given for methods of combating the disease. At present the only means seems to be remedial and consists in the destruction of all infested roots and greater attention to storage and fertilizers.

Tomato blight, G. W. HERRICK (*Mississippi Sta. Rpt.* 1899, pp. 43, 44).—In order to obtain some practical method of dealing with tomato blight, the author conducted a number of experiments during the season covered by the report. Seedlings were grown on infected soil and kept in the greenhouse where similar plants had been grown every year. Equal areas were planted in soils which had produced blighted tomatoes the year previous. One plat was treated with lime at the

rate of 4,000 lbs. per acre; the second plat was left as a check, and the third plat was treated with kainit at the rate of 400 lbs. per acre. The record obtained showed less blighted plants where the lime was employed than on the other plats.

In another experiment 2 plats of the same area were planted with seedlings grown on uninfected soil and in a greenhouse in which no seedlings had been grown. In one of the plats where blighted tomatoes had been grown the previous year, lime at the rate of 4,000 lbs. per acre was added. The other plat received no treatment, and a comparison of the yield of the 2 plats showed but slight difference in the percentage of blighted plants.

Another series of plats were tested the soil of which had never borne tomatoes. The first plat was planted with seedlings grown on infected soil and was treated with kainit at the rate of 400 lbs. per acre. Plat 2 was similarly planted but not treated. The third plat was similar in all respects except it received lime at the rate of 4,000 lbs. per acre. The fourth plat was set with seedlings grown on uninfected soil and treated with lime. In this series of experiments only 1 plant was blighted, and that was found on plat 3. The author states, as a result of his experiments, that "infection is not obtained in the greenhouse and that rotation of the crop is a benefit and probably necessary."

The relationship existing between the asparagus rust and the physical properties of the soil, G. E. STONE and R. E. SMITH (*Massachusetts Hatch Sta. Rpt. 1899, pp. 61-73*).—Attention was previously called by the authors (E. S. R., 11, p. 159) to the probable relationship existing between dry seasons and the occurrence of the summer or injurious stage of the rust. Continued observations have been made on this subject, and with but one exception the authors report that the rust has never been observed by them or reported to them except in soils which were sandy and possessed little water-retaining properties. Mechanical analyses of a number of soils of the State are given with their water-retaining capacity. The conclusion is reached that injury by the summer stage of the asparagus rust is due to a weakened condition of the plants from growing on dry soils during seasons of extreme drought. The practice of spraying for the prevention of the rust is not considered productive of good results. If the development of the rust is due to lack of moisture in the soil, it seems that it will be necessary to resort to soil of finer texture for the cultivation of the crop and the practice of irrigation wherever possible.

Fungus diseases of the roots of fruit trees (*Jour. Bd. Agr. [London], 7 (1900), No. 1, pp. 10-16, pl. 1*).—A number of young fruit trees were submitted to the board of agriculture, and it was found that they were apparently dying from the attacks of a fungus on the roots. The fungus belongs to the genus *Rosellinia* and threatens to

be a serious pest to various trees. On this account an article by G. Massee on a similar disease of the trees of New Zealand is extensively quoted.

As preventive measures it is suggested that the mycelium, which travels through the soil, may be isolated by digging deep, narrow trenches about the trees, care being taken to throw the excavated soil toward the tree instead of from it. A second method, which has proved of service in France, is to lay the trunk bare as far below the surface of the soil as can be done without injury to the tree and to cover the exposed trunk and soil with sulphur.

The brown spot of the apple, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt. 1899, pp. 159-164, pl. 1*).—In the Annual Report of this station for 1891 (E. S. R., 4, p. 471), attention was called to a fruit spot of the Baldwin apple which at that time was thought possibly to be due to a fungus which was determined as *Dothidea pomigena*. A re-examination of these brown spots has led to the conclusion that the disease is not primarily due to a fungus. In the past season numerous specimens of Baldwin apples have been examined. Beginning with the first evidences of fruit spot in the autumn before harvest, a careful search was made for bacteria and fungi, neither of which were found. In connection with these observations it was determined that while the spot is the worst in the case of the Baldwins it is also quite common on Northern Spy and was observed on Greenings. The spots are not uniformly distributed over the surface but are more numerous toward the apical portion of the fruit. They are not confined to the surface but appear at various depths, the deep ones often being overlaid by a half inch or more of sound flesh, and are associated in their distribution with that of the vascular bundles occurring at or near the ends of the veins which permeate the flesh of the fruit.

An examination of the literature led the authors to conclude that this disease is the same as that described by Wortmann¹ under the name of "stippen." This work is reviewed at some length and the characters of the disease are summarized. Its occurrence is rather widespread and, while preeminently occurring in the Baldwin apple, more than 30 other varieties are reported as having been attacked to some extent. The greatest damage done by this disease is in the appearance of the fruit, although at times a slight bitter flavor is said to accompany it. The author states the conclusions of Wortmann that the disease is a result of the concentration of the sap following a loss of water. Several factors enter into the problem of spot formation. Among them are the amount and rapidity of transpiration, the kind and relative amount of substances in solution in the sap, the conductivity of the tissues of the fruit, and the specific resistance of the

¹ Landw. Jahrb., 21 (1892), pp. 663-675.

protoplasm of the cells to the injurious action of concentrated sap. Remedies which have been suggested by numerous investigators are cited by the authors, although no experiments seem to have been made by them in controlling the disease.

Spraying for the prevention of apple scab, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt. 1899, pp. 156-159*).—In continuation of experiments reported in 1898 (E. S. R., 11, p. 356), a block of 5 trees near the middle of the orchard was experimented with, in which Paris green, copper sulphate, and Bordeaux mixture containing Paris green were compared, different rows of trees being sprayed a different number of times. The yield from the different trees is shown, and from the table the importance of early spraying and 1 or 2 applications of Bordeaux mixture after the blossoms have fallen is emphasized. The important point brought out by this investigation is that an apple tree which had not been sprayed in the experiments of 1897 and 1898, but was sprayed during the time of this experiment, bore more scabby apples than all the rest of the orchard where the trees were sprayed. This would indicate the importance of spraying every season and the cumulative effect to be derived from such treatment.

The prevention of peach-leaf curl, W. A. MURRILL (*New York Cornell Sta. Bul. 180, pp. 321-334, figs. 6*).—In Bulletin 164 of this station (E. S. R., 11, p. 164) the appearance and life history of the fungus causing the leaf curl of the peach are described at some length and results of experiments for its prevention are given.

In the present bulletin 2 years' experiments are summarized, which lead to the conclusion that leaf curl of the peach can be readily controlled when proper and timely treatment is given. The orchards selected for the experiments represented a variety of conditions of soil, moisture, and exposure, and were composed of a number of varieties of peaches, some of which were chosen on account of their well-known susceptibility to the disease. The plan of the orchard and outline of investigation for each of the experiments are given in detail.

The trees were sprayed with different strengths of solutions of Bordeaux mixture, potassium sulphid, ammoniacal copper carbonate, copper sulphate, and lime. Of the substances employed as fungicides, Bordeaux mixture proved most useful, and the treatment recommended for peach-leaf curl, based upon these and other experiments, is as follows:

"Spray with Bordeaux consisting of 6 lbs. of copper sulphate, 4 lbs. of good quicklime, and 50 gal. of water about the first of April when the buds are beginning to swell.

"Spray again when the petals have fallen with Bordeaux consisting of 2 lbs. of copper sulphate, 2 lbs. of good quicklime, and 50 gal. of water. If the weather of April and early May is warm and dry this second spraying may be omitted."

Investigations on the brunissure of plants, V. DUCOMET (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 171-283, pls. 3, figs. 60).—An historical review is given of the literature of brunissure and the conclusions of various authors as to its causes are briefly summarized. According to the summary, some authors hold that the disease is due to physiological causes, others to animal or vegetable parasites, while still others claim it is due solely to physical agencies acting upon the cell.

In the authors' investigations particular attention was paid to the brunissure of the grape. The disease, as characterized by the appearance of the different parts of the affected plants, is described at length and the results of a large number of observations and experiments are cited. Differences are noted in the degree of susceptibility of different races and varieties of grapes to this disease and its occurrence and characterization on a large number of other plants are given. The author concludes that brunissure is not of a parasitic nature but is rather due to physiological changes brought about by various causes such as sudden rising and falling of temperature, heavy precipitation, mechanical injuries, and abnormal conditions due to organic parasites.

The disease being due to physiological causes, the author advises attention to the growth and surroundings of the plants as a means for reducing or preventing attacks.

A stunted growth of vines, L. RAVAZ (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 293-314, pls. 6).—The author gives a preliminary report upon a peculiar stunted growth of grapevines to which the name *court-noué* is given. The principal characteristics of this disease is a remarkable shortening of the internodes of the vine attacked. The interior of the stem is discolored, being of a brownish-yellow or dark-brown color. The disease is said to be readily transmitted by cuttings and grafts and all affected material should be rejected. Some varieties are more susceptible than others and such should be discarded.

The parasitism of *Phoma reniformis*, L. RAVAZ and A. BONNET (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 284-293, pl. 1).—The authors review the work of Jackzewsky and Spechnew (E. S. R., 11, p. 1061) and take exceptions to the claim that *Phoma reniformis* is a parasite on the grape. The life history of the fungus is given, and experiments covering almost a year are described in which no evidence of parasitism was observed. The fungus is said to occur rather abundantly as a saprophyte, but is wholly unable to penetrate uninjured tissues. On this account it can not be considered as the primary cause of the very destructive disease of grapes in the Caucasus region.

Two hitherto unknown diseases of *Phlox decussata*, J. RITZEMA-Bos (*Tijdschr. Plantenziekten*, 5 (1899), No. 2, pp. 27-32).—The attacks

of *Tylenchus devastatrix* upon phlox plants may be recognized by the thicker and shorter stems and irregularly curled leaves of the infested plants. By the shortening of the internodes the leaves are brought close together and produce a characteristic deformity.

In combating this worm it is of considerable importance to cut off and burn all infested parts of the plant above ground, and deep plowing of the soil is also recommended.

The same species of phlox was observed in Brussels and other places to be attacked by a fungus disease which was caused by *Septoria phlogis*. The stems of infested plants remained short, and the leaf petioles were either thickened and shorter than usual or totally undeveloped. In general, the appearance of plants infested with this fungus disease was somewhat similar to that of plants which were attacked by the nematode worm, but the presence of yellowish spots in the case of the fungus disease served to distinguish the 2 diseases. The author recommends that infested plants be cut and burned.

A second partial list of the parasitic fungi of Vermont, L. R. JONES and W. A. ORTON (*Vermont Sta. Rpt.* 1899, pp. 164-182).—In continuation of the previous list noted in E. S. R., 11, p. 356, the authors give corrections of the first list, additional hosts for species there reported, and additional species not listed, together with the host plants bearing the fungi.

Plant diseases in Denmark during 1898, E. ROSTRUP (*Tidsskr. Landbr. Planteavl*, 6 (1900), pp. 38-56).

Cereal rusts with special reference to wheat rusts, G. LINHART (*Kísérlet. Közlem.*, 3 (1900), No. 2, pp. 140-163, pl. 1, figs. 13).

Potato scab (*Bul. Bot. Dept. Jamaica, n. ser.*, 7 (1900), No. 6, pp. 87-92).—Notes the occurrence of this disease in Jamaica and quotes extensively from bulletins of the Rhode Island Station (E. S. R., 5, p. 590; 7, p. 782; 8, p. 798).

Diseases of beets and beet seed, G. LINHART (*Kísérlet. Közlem.*, 3 (1900), No. 3, pp. 177-204).

Diseases of sugar cane (*Rev. Agr. Réunion*, 6 (1900), No. 1, pp. 5-11).—Descriptions are given of a number of diseases of cane due to various causes such as *Tricosphaeria sacchari*, *Bacillus vascularum*, *Ustilago sacchari*, *Cercospora vaginæ*, *Dioranotropis vastatrix*, *Collectotrichum fulcatum*, etc.

A stem disease of wheat, B. FRANK (*Deut. Landw. Presse*, 27 (1900), No. 53, p. 675, pl. 1).—Descriptive notes are given on *Ophiobolus herpotrichus*, a fungus that has been of serious injury to wheat in a number of German provinces.

Asparagus rust, J. STAPP (*Amer. Gard.*, 21 (1900), No. 295, p. 550).—Notes the occurrence of asparagus rust in Illinois.

Notes on a cantaloupe disease, C. S. CRANDALL (*Colorado Sta. Rpt.* 1899, p. 36).—A brief note is given on a cantaloupe disease at Rockyford, where it is said to have done much damage in the season of 1899. A grower is reported to have sprayed small areas with Bordeaux mixture with excellent results.

Cucumber troubles, B. T. GALLOWAY (*Amer. Florist*, 15 (1900), No. 627, p. 1382).—Gives an account of nematodes in cucumber roots and recommends steam sterilization of the soil in the house where the plants were grown as a means of relief.

A disease of cucumber plants, W. G. SMITH (*Gard. Chron.*, 3. ser., 27 (1900), No. 697, p. 274).—Describes the damping off of cucumbers which is due to *Pythium debaryanum*. This disease was particularly abundant in greenhouses during the past season. The author thinks its unusual occurrence was due to the cold spring, which

caused longer heating of the houses than usual and less frequent ventilation. As preventive measures he suggests more thorough ventilation and treating the soil with a small quantity of iron or copper sulphate.

Damping off of young cucumbers, E. JENKINS (*Gard. Chron.*, 3. ser., 27 (1900), No. 700, pp. 324, 325).—The author agrees with a previous writer that lack of ventilation is a cause of the destructive occurrence of the fungus which causes this disease in forcing houses.

Some diseases of orchard fruits (*Deut. Landw. Presse*, 27 (1900), No. 57, pp. 720, 721, fig. 1).—Notes are given on apple scab due to *Venturia inaequalis* and *Fusicladium dendriticum*, and pear scab caused by *F. pyrinum*.

Some observations on apple-tree anthracnose, A. B. CORDLEY (*Bot. Gaz.*, 30 (1900), No. 1, pp. 48-58, figs. 12).—Notes are given on the life history of *Gleosporium malicorticis*, the fungus which is said to be the cause of apple-tree anthracnose in Oregon (E. S. R., 12, p. 58).

The European apple canker in America, W. PADDOCK (*Science*, n. ser., 12 (1900), No. 295, pp. 297-299, fig. 1).—Specimens of diseased apple twigs have been received by the author from Nova Scotia and also from Cortland County, New York, which have been determined by Dr. R. Hartig as infected with the European apple-tree canker (*Nectria ditissima*). It is thought that this is the first record of the disease in America.

A gooseberry and currant disease, G. MASSEE (*Gard. Chron.*, 3. ser., 27 (1900), No. 698, p. 290, fig. 1).—This disease which is due to *Plowrightia ribesia* is said to have been rather abundant on gooseberries and currants, where it forms large, wart-like, black bodies, which burst transversely through the bark. A number of successful inoculation experiments were conducted by the author which showed that the organism is one of the wound fungi. As infested branches are invariably killed by it, it is suggested that they should be removed and burned on the first appearance of the disease.

The treatment of mildew and the preparation of copper fungicides, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 19, pp. 549-557, figs. 2).—Suggestions are given for treating grapes for mildew and formulas and directions for making a number of the more efficient fungicides.

Winter treatment against grape mildew, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 12, pp. 347, 348).—The proper time for combating mildew is in the spring and summer, winter treatments not giving results commensurate with their cost and labor. Bordeaux mixture, Burgundy mixture, and verdigris are recommended as the fungicides best adapted to the prevention of grape mildew.

Treatment of grape mildew, J. ARTIGALA (*Messenger Agr.*, 5. ser., 1 (1900), No. 6, pp. 218-223).—Formulas and directions for application are given for a number of fungicides, among them Bordeaux mixture, Burgundy mixture, ammoniacal copper carbonate, verdigris, neutral copper acetate, copper sulphate, corrosive sublimate, potassium permanganate, cadmium sulphate, and solutions containing sugar, resin, etc.

Potassium permanganate for combating grape mildew, C. TRUCHOT (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 11, p. 320).—Notes the successful use of this fungicide against mildew, etc., of the grape.

Coulure of grapes, L. RAVAZ (*Messenger Agr.*, 5. ser., 1 (1900), No. 5, pp. 168-171).—Under this name the author describes a disease of grapes that seems to be probably identical with that described by Lodeman (E. S. R., 6, p. 732) under the name "shelling" or "rattling" of grapes.

The rusts of florists' plants, B. D. HALSTED (*Amer. Florist*, 15 (1900), No. 623, p. 1268).—Briefly describes the rusts of hollyhocks, carnations, and chrysanthemums.

A natural check for carnation rust, F. H. BLODGETT (*Amer. Florist*, 15 (1900), No. 623, p. 1268, figs. 2).—Gives brief popular notes on the parasite (*Darluka filum*) of carnation rust.

Fairy ring of carnations (*Jour. Hort.*, 52 (1900), No. 2683, p. 188).—Notes the occurrence of *Heterosporium echinulatum* on leaves of carnations and recommends spraying or sponging diseased plants with a solution of potassium permanganate.

The clematis disease, J. JENSEN (*Amer. Florist*, 15 (1900), No. 625, pp. 1349, 1350).—A disease caused by nematodes, and methods of prevention.

Diseased iris leaves and roots (*Jour. Hort.*, 52 (1900), No. 2700, p. 559).—Notes the occurrence on iris of a fungus similar to if not identical with *Botrytis galanthina*. The leaves are first attacked, later the roots, the plant not surviving the injury. Rotation and fertilization are recommended as remedial treatments. Removing diseased parts of plants and dusting with powdered copper sulphate are also advised.

Diseases of the rose, B. D. HALSTED (*Florists' Exchange*, 12 (1900), No. 13, pp. 333, 334, fig. 1; also *Amer. Florist*, 15 (1900), No. 617, pp. 1033-1037).—In a paper read before the American Rose Society, March 28, 1900, the author describes a number of the more common diseases of the rose and suggests methods for treatment. The diseases described are nematodes, black spot, rose-leaf blight, rose mildew, downy mildew, rose rust, rose anthracnose, leaf spot, black speck, and bronzing.

Diseased violets (*Jour. Hort.*, 52 (1900), No. 2683, p. 188).—Mentions attack of *Peronospora violæ* on violets. Recommends better ventilation and sprinkling powdered lime over diseased plants.

Liquid and powder fungicides, P. CARLES (*Messenger Agr.*, 5. ser., 1 (1900), No. 7, pp. 260-263).—Formulas and directions are given for the preparation of Bordeaux mixture of different strengths, Burgundy mixture, and a powder which consists of 750 gm. basic copper acetate and 1,250 gm. of pulverized plaster.

Spraying of fungicides, E. BRINGUIER (*Messenger Agr.*, 5. ser., 1 (1900), No. 5, pp. 171-174).—A critical statement on the preparation and application of fungicides.

A cyclone spray pump (*Queensland Agr. Jour.*, 6 (1900), No. 5, p. 381, fig. 1).—A cheap form of spray pump is figured and described.

ENTOMOLOGY.

Report of the State entomologist, E. P. FELT (*Bul. New York State Mus.*, 6 (1900), No. 31, pp. 531-653).—The report contains a general discussion of the work of the entomologist for the year in the field, office, and laboratory. Brief notes are given on the biological and economic relations of the following insects: Raspberry sawfly, locust borer, elm-leaf beetle, asparagus beetles, antiopa butterfly, forest tent caterpillar, and the seventeen-year cicada.

Experiments were conducted with arsenical poisons as treatment for the attacks of the elm-leaf beetle. Twigs of the English elm were placed in small water bottles which were kept in experiment cages. The leaves were sprayed by means of an atomizer with different arsenicals. The results obtained from these experiments indicate that arsenate of lead is slow in its action, but experiments conducted in the field indicate that when the application is thorough it is a very effective insecticide. Paris green, London purple, Paragrene, and lead arsenate were the arsenicals used in these experiments. An experiment upon nearly full-grown forest tent caterpillars demonstrated that this insect could be controlled by arsenical applications and that arsenate of lead was an effective spray for this purpose.

A detailed report is made on the volunteer entomological service of the State. The volunteer observers now number 43 and are located in 39 counties. A summary is given of the report from each observer. The author gives a list of 82 insects, specimens of which have been exhibited at farmers' institutes and similar gatherings for the purpose of giving instruction in the economic relationships of insects. A list is given of newspaper articles and other publications of the entomologist for the year.

Thirtieth annual report of the Entomological Society of Ontario, 1899 (*Rpt. Ontario Ent. Soc. 1899, pp. 127, pls. 2, figs. 66*).—This report contains the proceedings of the thirty-sixth annual meeting of the Entomological Society of Ontario, held in London, October 11 and 12, 1899, and the proceedings of the first annual meeting of the Northwest Entomological Society, held at Lacombe, Alberta, Northwest Territories, November 7, 1899.

A conference was held on the San Jose scale, during which W. Lochhead presented a paper on the economic aspect of the San Jose scale and its allies. A general discussion followed this paper.

The annual address of the president of the Entomological Society of Ontario contained suggestions regarding the organization of an entomologists' union, notes on the milkweed butterfly and other insects.

F. M. Webster presented a popular history of the past century of American entomology, and briefly discussed the subject of the native home of the San Jose scale (pp. 55, 56). The same author gave a brief note on the larval habits of *Uranotes melinus*.

W. Lochhead presented notes on some insects found on coniferous shade trees. These notes covered the subjects of the economic importance, life history, and habits of *Chermes abietis* and *Lygconematus erichsonii*. The attraction of electric light for moths was discussed by A. Gibson. It was noted that the male insects were attracted in much greater numbers than the females.

A paper on the injurious insects of the orchard, garden, and farm for the season of 1899 was read by W. Lochhead. This paper contained a discussion of the history and life habits of the codling moth, bud moth, tent caterpillars, several species of scale insects, Colorado potato beetle, squash bug, cabbage worm, cabbage aphid, grapevine leaf hopper, wheat-stem maggot, clover-root borer, etc.

C. J. S. Bethune reported a case of fatal bite from *Sinca diadema*. Brief notes were given by J. A. Moffat upon some Cuban insects—*Polistes lineata*, *Chloridea virescens*, etc. The same author discussed the wing structure of the milkweed butterfly.

A paper on Nature-study lessons upon the cabbage butterfly was read by W. Lochhead. T. W. Fyles gave an account of the structure, habits, and classification of spiders. Under the title "Notes on insects

of the year," W. H. Harrington gave brief accounts of the grain aphid, cabbage butterfly, pea weevil, currant aphid, tent caterpillars, etc.

J. D. Evans presented a brief note on the tent caterpillars, and A. Gibson gave a short account of the tussock moth, onion maggot, red spider, and *Rhopalosiphum violæ*. J. A. Moffat discussed the milkweed butterfly and other insects. C. J. S. Bethune presented a brief account of the tent caterpillars, squash bug, etc. T. W. Fyles gave an account of the tent caterpillars, milkweed butterfly, *Harpiphorus tarsatus*, *Tenebrioides mauritanicus*, *Metzneria lappella*, etc.

J. Fletcher gave an account of the appearance and destructiveness of a number of injurious insects, among which may be mentioned the asparagus beetle, scale insects, the destructive pea louse, black violet aphid, etc. C. J. S. Bethune reported some observations on the bumble-bee's nest.

The proceedings of the first annual meeting of the Northwest Entomological Society include a report of the council, the president's address, and other brief notes.

Report of the entomological section, C. P. GILLETTE (*Colorado Sta. Rpt. 1899, pp. 37-41*).—Observations made upon the codling moth indicate that the insect is completely two-brooded, with no evidence of a third brood. Good results were obtained in fighting it by banding the trees. Kerosene emulsion was found to be practically valueless against the codling moth.

In making a study of the grasshoppers of the State it was found that the 2 species most concerned in injuries to cultivated crops were *Melanoplus bivittatus* and *M. differentialis*. Not a single specimen of the Rocky Mountain locust has been seen in the State for the past 9 years. The beet army worm (*Laphygma flavimaculata*) caused severe losses to the sugar-beet industry, 200 or 300 acres of beets being completely ruined by the attacks of this insect in the caterpillar stage. Field experiments demonstrated that the ordinary arsenical poisons are quite effective against it. The ash borer (*Podosesia syringæ*) is reported as rapidly increasing in numbers and as having killed many ash trees. Experiments conducted with arsenical mixtures indicate that Green Arsenoid and Pink Arsenoid are rather effective, while White Arsenoid was too injurious to the foliage.

Experiments have been conducted in the apiary for the purpose of determining the best form of foundation for comb honey and the best method of using the foundation in a section.

A new sugar-beet pest and other insects attacking the beet, R. W. DOANE (*Washington Sta. Bul. 42, pp. 14, figs. 5*).—Since October, 1896, the author has made observations on a new beet aphid (*Pemphigus betæ*) which was found, upon investigation, pretty generally distributed in the beet fields of the State.

The author gives a technical description of the species. The body

of the insect, including the legs and antennæ, is said to be covered with a white flocculent powder. Late in the season winged forms appear. The native food plants of the insect appear to be *Achillea lanulosa* and *Polygonum aviculare*. The insect passes the winter in the soil on or near the roots of the food plants. No males have been discovered in this species.

A wet spring followed by an early dry summer seems to be especially favorable to the multiplication of this insect. The prevalence of the beet aphid seems not to be conditioned by the character of the soil. No direct remedies are suggested. In the line of prevention the author recommends that beets should not be planted on new soil, since the native plants growing on such soils might be already infested. It is urged further that beets should not be grown for many seasons in succession upon the same ground.

Brief notes are given on the habits and life history of and remedies against *Psylliodes punctulata* and *Carneades messoria*.

Notes on a new sugar-beet pest with a description of the species, R. W. DOANE (*Ent. News*, 11 (1900), No. 3, pp. 390, 391).—A species of plant louse is described as new under the name *Pemphigus betæ*. The ordinary host plants of this species are *Polygonum aviculare* and *Achillea millefolium*. The insect lives upon the roots of these plants and is recognized by the flocculent secretion upon its body. Recently this species has attacked sugar beets and is becoming an insect of considerable economic importance. During the winter months the colonies of this insect consist of individuals in all stages of development. These colonies grow rapidly during April and May. During the summer, winged forms appear and increase in number until about the middle of November. They leave the plant and fly for considerable distances in search of new host plants. A technical description of the insect is added.

The grass thrips, W. E. HINDS (*Massachusetts Agr. Col. Rpt.* 1899, pp. 83-97, pls. 4).—The author made a study of an outbreak of the grass thrips which occurred in Massachusetts. The species was considered to be *Anaphothrips striata*. For the purpose of studying this species, specimens were brought into the laboratory and kept, in large-mouthed bottles, upon the stems of silver-topped June grass, which seemed to be the food plant preferred by them. It was observed that the females deposit their eggs in the fresh and tender portions of the leaf tissue. Oviposition takes place at night as well as in the daytime. The females which have passed the winter begin laying eggs very soon after the beginning of growth in the grass. The process of egg laying continues for 4 or 5 weeks and the number of eggs laid by a single insect in confinement averages about 50 to 60. The eggs of these hibernated females hatch in from 10 to 15 days, but during the summer generations the eggs hatch in from 4 to 7 days. The mature larvæ

select secluded places for pupation, either within the sheaths of the upper leaves or in the sheaths of leaves at the base of the stem. The duration of the pupal stage in the first generation is from 6 to 8 days. The various stages of the insect are described in a technical manner. Two forms of adult females are to be observed, one with wings and the other with only short wing pads.

About 98 per cent of the hibernating adults are wingless and from 90 to 95 per cent of the first spring generation develop wings. The females deposit eggs and young larvæ are to be found on the grass until winter, but only adults survive the winter. Specimens survived after being exposed to a temperature of 21° F. below zero. The laboratory work indicates that there are 8 or 9 generations per year, the length of the life cycle varying from 30 days for the first generation to 12 days during hot weather. No males were found, and it is believed that the species is parthenogenetic.

The adult insects feed upon the leaves of grass and are seldom found within the sheaths. The larvæ, on the other hand, seek more protected places for feeding. The greatest damage is done by this insect to June grass (*Poa pratensis*), timothy, and barnyard grass, but a considerable variety of other grasses are attacked. The females hibernate above ground and it is, therefore, suggested that burning in early spring would destroy great numbers of them. It was also observed that the injury from this insect was most severe on worn-out meadows and on fields that had been seeded for many years and had become partly exhausted. The author recommends, therefore, the application of fertilizers and deep plowing of old fields, to be followed with a cultivated crop for at least one year before reseeding.

Codling moth; a wasp that destroys the apple worm, U. P. HEDRICK (*Utah Sta. Bul.* 64, pp. 31-42, figs. 7).—The author's experiments in spraying for the codling moth have led to the conclusion that in Utah 4 sprayings are advisable for summer apples and 6 for winter apples, and that white arsenic is more effective than Paris green even when the latter is unadulterated.

The solution used in these experiments was made as follows: White arsenic 1 lb., unslacked lime 2 lbs., water 3 gal., the mixture to be diluted in 200 gal. of water. The applications were made on the following dates: June 6, June 21-22, July 11-12, July 24-25, August 13-14, and a sixth spraying during the first week of September. The cost of the 6 applications was about 25 cts. per tree. A table is given showing the number of trees of each variety sprayed and the number of wormy and sound apples gathered from these trees. The experiments were conducted upon 20 varieties of apples.

The author made observations upon a digger wasp (*Ammophila prunosa*) which was observed preying upon the codling moth in an orchard near Logan. The wasps occupied 2 areas of about 4 and 1 sq.

rod extent, respectively. On August 20, 1898, the wasps were seen eating the cabbage worm and also the codling moth. The apple trees were loaded with fruit and were almost free from the codling moth, which was considered remarkable in view of the fact that apples in that region are usually badly infested. The owner had never been under the necessity of spraying these trees. The author collected a few larvæ of the codling moth and scattered them near the burrows of the wasps, and they were greedily seized upon by the latter. As a rule, the wasps cover the opening of their burrows upon leaving them. In an area 18 in. square 39 closed burrows were found with a depth of from 4 to 8 in. and a diameter of $\frac{1}{4}$ in. The burrows were for the most part unbranched, and at the terminus was to be found sometimes a single cocoon and at other times from 1 to 3 larvæ of the codling moth. The author describes the method by which the larvæ of the wasp feed upon the codling moth.

The apple plant louse, J. B. SMITH (*New Jersey Stas. Bul.* 143, pp. 23, figs. 32).—From observations made by the author during the past 3 years, it is concluded that the apple plant louse upon apple trees in New Jersey has no alternate food plant and, therefore, no "migrant" or "return migrant" forms. The species is *Aphis mali*, and may be distinct from the one which has been described by other authors as migrating from the apple tree to other food plants. On November 1, 1898, the author began observations upon a tree which was badly infested with this species. At this date many eggs had already been laid, and it was observed that both sexes of the insect were wingless. When the plant lice began to develop in the spring of 1899, daily observations were made for a time and specimens were collected at frequent intervals during the season.

The author reports in detail his observations upon the appearance and habits of the various generations which occur during a season, noting the anatomical characters by which the different generations may be distinguished. The life history of the apple plant louse, as observed by the author, may be summarized as follows: The species hatches from the egg as soon as buds develop in earliest spring. The stem-mother becomes mature and begins to reproduce about 15 days later. After another period of 9 or 10 days the second generation becomes mature, and it was observed that about three-fourths of this generation were winged. Two weeks later the third generation becomes developed, and about one-half of the individuals of this generation are winged. During the whole year there are 7 generations of parthenogenetic females, but no winged individuals are to be found except in the second and third generations. The winged forms leave the trees upon which they have developed, fly to other apple trees, and in this way bring about the wide distribution of this species. The individuals which fly from one tree to another are not to be regarded as repre-

senting the migrant forms, since there is no migration from the apple tree to other food plants. Sexed individuals appear in October, egg laying begins about the tenth of the month and continues until the latter part of November or first part of December.

Among the natural enemies of this insect observed by the author may be mentioned the following: Ladybirds, syrphus flies, lacewings, parasitic Hymenoptera and Diptera, and a fungus disease. As artificial remedies against the apple plant louse the author recommends spraying with the following insecticides: Kerosene emulsion mixed with 12 parts of water; a 5 per cent mechanical mixture of kerosene with water; fish-oil soap at the rate of 1 lb. in 6 gal. of water, or a tobacco decoction in a strength equal to an extract of 1 lb. of tobacco in 2 gal. of water. The insects are most vulnerable soon after hatching from the eggs, and the author recommends at this time a treatment with tobacco soap made by adding tobacco to a potash soap. Tobacco combined with fish-oil soap also gave satisfactory results. If the trees should become badly infested in summer, they may be sprayed with a strong solution of any of these substances late in September or during the first part of October.

Since the distribution of the insect is largely accomplished in the egg state on nursery stock, it is recommended that such stock be fumigated with hydrocyanic-acid gas before being sent out.

The forest caterpillar, G. H. PERKINS (*Vermont Sta. Bul.* 76, pp. 111-137, *figs.* 13).—The ravages of the forest tent caterpillar began to attract attention in Vermont in 1895. Serious outbreaks also occurred in 1896, 1898, and 1899. The author states that in many localities the damage of maple trees was not entirely due to the forest tent caterpillar, but that *Plagionotus speciosus* and the fall cankerworm committed serious depredations. It is stated that the forest tent caterpillars were so numerous in Montpelier that one man was able to collect 10 bu. of the caterpillars in 2 weeks' time. The author gives a description of the insect in its various stages, together with notes on its feeding habits and life history. Quotations are also given from letters of correspondents which show the great ravages committed by this insect upon shade trees and sugar maples, the damage to the latter being so severe that the customary amount of maple sugar will probably not be produced in Vermont for several years to come. Brief notes are given on the bird and insect enemies of the forest tent caterpillar. Of several hundred caterpillars collected in Addison County only one-third developed moths, the remainder being destroyed by *Pimpla conquisitor*. In another lot of 200 cocoons hatched in the laboratory, only 30 produced moths. A disease, apparently of bacterial origin, has also been observed among caterpillars.

Notes are given on the most approved methods of destroying the eggs, spraying, banding the trees, destruction of cocoons, and capture of moths.

Caterpillar plague, H. TRYON (*Queensland Agr. Jour.*, 6 (1900), No. 2, pp. 135-147, pls. 3, fig. 1).—This article contains a general discussion of *Leucania unipuncta*, including an account of its food plants, a description of the insect in its various stages, notes on its habits, life history, distribution, and prevalence in Queensland. Among the insect parasites of this species the following may be mentioned: *Theronia rufipes*, *Erephanes leucaniv*, *Limnomyia nigripalpus*, *Paniscus productus*, and *Apanteles ruficrus*. The first 3 species are described as new and are said to be of considerable economic importance. *Calosoma australis* is one of the more important of the predaceous insect enemies of *Leucania*. The following birds are reported as being effective in the destruction of the army worm: *Dacelo gigas*, *Strepera graculina*, *Corvus australis*, etc. The usual artificial remedies for the army worm are described and recommended.

Plague locusts, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 11 (1900), No. 3, pp. 175-183, pl. 1).—A locust plague of considerable importance visited parts of Australia during the season of 1899, the species concerned being *Epacromia terminalis*. The author made a number of observations upon the numbers and habits of this species. The eggs were deposited in open red soil. It was observed that the number of males was far larger than that of females, there being about 40 of the former to one of the latter. A number of female locusts were examined for the purpose of determining the number of eggs, and 19 eggs were found in each locust examined. The locusts caused considerable damage to young grass and wheat. A description is given of the male and female of this species. The author recommends burning over the ground in order to destroy the young locusts soon after hatching. The leaves of the common garden larkspur and of the castor-oil plant were observed to be poisonous to the locusts. Locusts which ate the leaves and flowers of the larkspur died very quickly. A number of experiments were tried in spreading the African locust fungus among the locusts, but these experiments were begun too late in the season to be most effective, as the locusts had already acquired the power of flight.

Orchard technique: IV. Spraying the orchard, W. B. ALWOOD (*Virginia Sta. Bul.* 100, pp. 81-104, figs. 10).—The author gives details with regard to the spraying done in 1899 in an old neglected orchard which came under the care of the station. The first spraying was done March 17 with a solution of bluestone, the second April 28 with Bordeaux mixture, and the third May 12 with Bordeaux mixture to which was added 8 oz. of green arsenite to 50 gal. of Bordeaux. The total expense of these 3 applications was about 16.2 cts. per tree.

Three sprayings were carried out on a young orchard, March 13, April 26, and May 16-17. The first application was a weak solution of bluestone, the second bluestone, and the third green arsenite. The

total cost of the 3 applications amounted to 3.8 cts. per tree. The application of Bordeaux mixture and green arsenite is made for the purpose of checking apple scab, orange rust, leaf curl of peach, and destroying the tent caterpillar, bud moth, cankerworm, and curculio. A second application of the Bordeaux mixture and arsenical poison is made for the same purpose and for the additional purpose of destroying the codling moth. Figures are given showing the proper stages of the leaf, buds, and young fruit of the apple at which the various applications should be made. The author recommends a winter application of a weak solution of lye to trees for the purpose of ridding the trees of lichens, destroying hibernating forms of insects, and as a fungicide treatment for apple scab and brown rot. Such treatment is given at any time during the dormant period of the trees. Experiments in the winter treatment of the San Jose scale indicated that pure kerosene with a flash test of 120 to 150° is the cheapest and surest winter wash. The author gives brief notes by way of description of methods of making some of the common fungicides and insecticides together with a short account of the fire blight of pear.

Report of the entomologist, C. H. FERNALD (*Massachusetts Hatch Sta. Rpt. 1899, pp. 98-102*).—The San Jose scale is reported in 30 localities within the State. The entomological department has been authorized to inspect nurseries upon request by the owners. Brief notes are given on *Phytonomus nigrirostris*, gypsy moth, and brown-tail moth. It is stated that F. J. Smith, of the Gypsy Moth Commission, has determined the composition of Raupenleim, so that this substance may now be manufactured in the United States.

Report on economic entomology for the year 1899, G. H. CARPENTER (*Rpt. Council Roy. Dublin Soc., 1899, pp. 15, figs. 16*).—The author presents biological and economic notes on a number of farm and garden insect pests, including, among others,* crane flies, death's-head moth, *Smerinthus ocellatus*, *Otiorrhynchus sulcatus*, *Tyroglyphus longior*, and *Hippobosca equina*.

Report of the Swedish state entomological station for 1899, S. LAMPA (*Meddel. K. Landtbr. Styr., 1900, No. 65, pp. 48*).

Common diseases and insects injurious to fruits, S. A. BEACH, V. H. LOWE, and F. C. STEWART (*New York State Sta. Bul. 170, pp. 381-445*).

"The purpose of this bulletin is to furnish the fruit grower with a concise account of the common diseases and insects most injurious to cultivated fruits in New York State and to present up-to-date directions for fighting them most efficiently and economically. . . . The various fruits are taken up in alphabetical order and under each one the diseases are first considered, then the insects. In the consideration of each particular disease or insect, it is the general plan of the bulletin to give first one or more descriptive paragraphs setting forth its general appearance, the chief features of its life history, and its economic importance. Then follows a statement of the remedial or preventive treatment which is recommended or suggested by the authors. Where nothing can be positively recommended, suggestions are made, pointing out what appears to be the most promising line of treatment."

The usefulness of the bulletin is much increased by the addition of an index of the fruits, diseases, and common and scientific names of insects and fungi.

Plant diseases and insect pests, C. P. CLOSE (*Utah Sta. Bul. 65, pp. 57-97, pls. 6, figs. 5*).—This is a popular bulletin containing brief notes on approved methods of

making insecticides and fungicides, and a brief account of some of the more common fungus and insect enemies of fruit trees.

Insects injurious to forest trees, E. P. FELT (*Rpt. New York Com. Fisheries, Game, and Forests, 1898, pp. 31, pls. 3, figs. 11*).—The author gives a brief general account of the habits and metamorphoses of insects. Special consideration is given to the forest tent caterpillar, the leopard moth, *Sesia aerni*, *Plagionotus speciosus*, *Elaphidion villosum*, and *Pulvinaria innumerabilis*. In connection with each one of these insects, the author discusses its life history, food plants, natural enemies, and the approved remedies for combating it.

The significance of the terms phagocytosis and lyocytosis, J. ANGLAS (*Compt. Rend. Soc. Biol. Paris, 52 (1900), No. 9, pp. 219-221*).—In a study of the metamorphosis of Hymenoptera, especially of the genera *Vespa* and *Apis*, the author states that the disappearance of the larval organs or of the larval reserve food materials does not take place by phagocytosis, but that the process is better described as a chemical degeneration and dissolution produced by the extracellular digestive action of leucocytes and of other cells. This process is called lyocytosis by the author.

Bot flies, gadflies, and breeze flies, J. G. O. TEPPER (*Jour. Agr. and Ind. South Australia, 3 (1900), No. 7, pp. 564-566*).—Notes on the life history and habits of species of *Tabanus*, *Cestrus*, *Hypoderma*, and *Gastrophilus*.

The food of certain caterpillars of the Bombycidae, L. DEMAISON (*Bul. Soc. Ent. France, 1900, No. 2, pp. 22, 23*).—Notes on the feeding habits of *Bombyx quercus*, *Megasoma repandum*, *Orgyia antiqua*, etc.

Combating *Anthonomus pomorum* (*Hessische Landw. Ztschr., 70 (1900), No. 11, p. 142*).—Experiments were tried in scraping the loose bark from 12 apple trees and painting on a band of axle grease. The bands were painted on the trees on January 17 and were inspected 14 times between that date and May 10. In all, 625 beetles were caught, with an average of 52 to the tree. It was observed that the insect was most plentiful in the period from the end of March to the end of April.

A contribution to the life history of *Cartharia pyrenæalis*, T. A. CHAPMAN (*Ent. Mo. Mag., 36 (1900), No. 431, pp. 75-78*).

A new gall gnat of the grapevine (*Clinodiplosis vitis*), G. LÜSTNER (*Ent. Nachr., 26 (1900), No. 6, pp. 81-84, pl. 1*).—The insect appears to be double brooded, the larvæ of the first generation being found in June and July and those of the second generation in August and September. The larvæ are found on the under side of the leaves and in the berries during the summer, and half-grown individuals were found in winter among the hairs of the leaf buds. Adults were seen from the beginning of September until November. Brief descriptions are given of the insect in its various stages. The eggs were found on brown spots of the leaves.

Galls on the leaves of *Jambosa domestica*, L. ZEHTNER (*Indische Natuur, 1 (1900), No. 1, pp. 3-11, figs. 3*).—The author describes the appearance and structure of galls produced chiefly on the under side of the leaves of this tree by an insect belonging to the Psyllide. The insect is described and figured in its various stages. As remedies, the author suggests the removal and destruction of infested leaves.

***Lasius fuliginosus* and its habits of rearing fungi**, G. LAGERHEIM (*Ent. Tidskr., 21 (1900), No. 1, pp. 17-29, figs. 7*).—The author made a detailed study upon the nature of a fungus found in the burrows of this species of ant. The fungus should apparently be referred to *Cladotrichum microsporum*. According to the author's observations, the fungus may be of only slight importance as a source of nutriment for the ants, but its luxuriant growth through all the chambers of the ant colony may assist in preventing the crumbling of the walls of these burrows.

The author believes that the presence of the fungus in the ant burrows is due to the deliberate care which the ants bestow upon the fungus and not to the inability of the ants to keep the fungus out.

Life history of *Margarodes flegia*, H. G. DYAR (*Canad. Ent.*, 32 (1900), No. 4, pp. 117, 118).—The author gives descriptions of the different larval stages of this insect, which is reported as injurious to *Thevetia neriiifolia* at Key West, Fla.

The fight against the Nun (*Ocneria dispar* L.), Y. SJÖSTEDT (*Meddel. K. Landtbr. Sty.*, 1900, No. 60, pp. 29).

A parasitic organism in the intestine of *Olocrates gibbus*, L. LÉGER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 11, pp. 261-263).—In the intestine of this beetle the author found a parasitic fungus to which the name *Rhaphidospora* is given. This parasite attacks epithelial cells of the intestinal wall. Its systematic position was not determined by the author.

The development of the wing in the *Lepidoptera*, W. F. MERCER (*Jour. New York Ent. Soc.*, 8 (1900), No. 1, pp. 1-20, pls. 5).—Detailed anatomical studies on the wing development of *Pieris rapæ*.

The systematic position of the locust fungus imported from the Cape, D. McALPINE (*Agr. Gaz. New South Wales*, 11 (1900), No. 3, pp. 184-186, pl. 1).—After a careful study of this fungus, which has been used with considerable success in destroying locusts in South Africa and has also been imported into parts of Australia, the author concludes that his original determination of this species was correct and that the fungus should be referred to *Mucor racemosus*.

Fumigation of nursery stock, S. A. BEACH (*New York State Sta. Bul.* 174, pp. 8, figs. 2).—The author gives a general account of the necessary apparatus and chemicals, and the method to be adopted in applying the treatment by hydrocyanic-acid gas to infested plants. A description is also given of a fumigation house which is suitable for this purpose.

Insecticides, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt.* 1899, pp. 147, 148).—Analyses are briefly reported of the following substances: Paris green, green arsenite, Laurel green, Bug Death, and Herbicide.

FOODS—ANIMAL PRODUCTION.

Food products examined, E. F. LADD (*North Dakota Sta. Rpt.* 1899, pp. 12, 13).—The author reports the composition of a number of samples of foods and feeding stuffs, including wheat breakfast food, wheat, flax bolls or hulls, spelt, spelt husks, and beef from a 3-year-old steer and from a cow 7 years old. The digestibility of the samples of beef cooked and uncooked was tested with pepsin solution. The results obtained follow:

Digestibility of cooked and uncooked beef in pepsin solution.

	Amount digested.			
	In 1½ hours.	In 3 hours.	In 6 hours.	In 18 hours.
COOKED.	Per cent.	Per cent.	Per cent.	Per cent.
Porterhouse steak from 3-year-old steer	89.10	90.60	95.50
Leg roast from 3-year-old steer	88.70	91.20	94.70
Leg roast from 7-year-old cow	86.90	90.00	94.80
RAW.				
Porterhouse steak from 3-year-old steer		95.4	94.8	96.3
Leg roast from 3-year-old steer		91.7	93.8	95.2
Leg roast from 7-year-old cow		91.6	93.2	95.2

The relative digestibility of several sorts of fat by man: IV. On artificial culinary fats and their digestibility as compared with lard, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 3 (1900), No. 2, pp. 73-87).—In continuation of work previously reported (E. S. R., 11, p. 660) experiments with a healthy man were made on the digestibility of lard, a commercial lard substitute, and a mixture of equal parts of the two, consumed with a mixed diet. The tests were of 3 days' duration. The average results follow: •

Digestibility of lard and commercial lard substitute.

	In daily food.	In daily feces.	Digested.
	Grams.	Grams.	Per cent.
Lard eaten with simple mixed vegetable diet.....	102.72	5.83	94.33
Commercial lard substitute eaten with simple mixed vegetable diet.....	102.77	5.89	94.27
Mixture of lard and commercial lard substitute eaten with simple mixed vegetable diet.....	102.72	5.46	94.68

Introducing corrections for the lecithin of the feces and the total fat in the ether extract, which is not saponifiable, the digestibility of the 3 sorts of fat would be 96.36, 96.09, and 96.47 per cent, respectively.

The author concludes that, although the digestibility of the 3 sorts of fat was practically the same, the lard is much to be preferred for other reasons. He considers pure lard a satisfactory product, while the commercial lard substitute was a mixture of inferior animal fat with vegetable oils.

The feeding value of sorghum as shown by chemical analysis, R. W. THATCHER (*Nebraska Sta. Bul. 62*, pp. 65-72).—Analyses are reported of Early Amber sorghum cut (1) when the canes were 2 ft. high, (2) when the canes were 4 ft. high with a very few heads appearing, (3) when headed out, most of the plants being in bloom, and (4) after heading, most of the seeds being in the dough stage. The first two samples were analyzed immediately after cutting and the last two after curing. The composition of the different cuttings follows:

Composition of sorghum at different stages of growth.

	Water.	Water-free material.								Albu- minoid nitro- gen.
		Pro- tein.	Fat.	Nitro- gen- free ex- tract.	Re- duc- ing sugars.	Su- crose.	Crude fiber.	Ash.	Nonal- bumi- noid nitro- gen.	
	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.
Canes 2 ft. high (analyzed uncured)	87.68	10.60	3.64	42.60	(a)	(a)	28.12	15.04	0.55	1.15
Canes 4 ft. high (analyzed uncured)	85.09	6.95	2.48	45.47	11.87	.00	33.37	11.73	.27	.84
Heading out, most of the plants in bloom (analyzed cured)		4.66	2.14	53.35	16.37	.00	31.62	8.18	.16	.59
After heading, seeds in dough stage (analyzed cured)		3.85	1.99	47.58	19.06	.00	38.44	8.19	.15	.47

a Not determined.

On the basis of these analyses the feeding value of sorghum is discussed and compared with other crops.

"The feeding value of sorghum is greatest when the plant is young. As the plant matures, the feeding value decreases rapidly. Therefore the crop should be used, for pasture, at least, before the seeds form, and for hay at as early a stage as it can be well cured. Analyses of sorghum when young and of other pasture plants at the same stages of growth show that it is somewhat deficient in flesh-forming material, containing less than blue grass or *Bromus inermis*, about the same as timothy, and a little more than Indian corn. Analyses of sorghum fodder, in comparison with other fodders and hay crops, show it to have a somewhat smaller amount of flesh-forming material than most hay crops, and less than corn fodder, but more than straw of the small grains. The fondness which live stock evince for this fodder is doubtless due to its sweetness."

The digestibility of American feeding stuffs, W. H. JORDAN and F. H. HALL (*U. S. Dept. Agr., Office of Experiment Stations Bul. 77, pp. 100*).—The value of digestion experiments with farm animals is discussed, as well as the methods generally followed and the extent of work of this nature at the experiment stations in the United States. The results of all such experiments with different farm animals, made up to the close of 1898 (378 in number), are summarized in tabular form. The material is also arranged to show the maximum, minimum, and average coefficients of digestibility of the principal feeding stuffs. The effect of individual peculiarity and the kind of animal upon digestibility is discussed, as well as the influence of the stage of growth of the feeding stuff, cooking, drying and curing, ensiling, grinding, wetting, quantity fed, and proportion of nutrients. This bulletin is designed to take the place of a compilation of a similar nature published several years ago (*E. S. R., 6, p. 5*).

Feeding young cattle, H. H. GRIFFIN (*Colorado Sta. Rpt. 1899, pp. 56, 57*).—A feeding test was made at the Arkansas Valley Substation with 15 calves 7 to 10 months old. The average weight November 18 was 342.6 lbs. each. They were fed on alfalfa hay until December 1, and were then given a pound of corn chop per head daily. This amount was gradually increased until in 2 weeks they were fed 3 lbs. per head daily. A few sugar beets were then added to the ration. January 1 the calves were divided into 3 lots of 5 each and fed corn chop with sugar beets or oats, alfalfa hay being given *ad libitum*. On an average the calves were fed 178 days. At the conclusion of the test they were sold for \$4.60 per hundred, deducting 3 per cent for shrinkage. The financial returns are based on alfalfa hay and sugar beets at \$3 per ton, chop at 80 cts., corn at 70 cts., and oats at \$1 per hundredweight. The average daily gain, less shrinkage, was 1.49 lbs., and the cost of a pound of gain $3\frac{1}{3}$ cts. In the author's opinion this test for the production of "baby beef" was successful.

The production and marketing of wool, H. W. MUMFORD (*Michigan Sta. Bul. 178, pp. 59-90, figs. 8*).—The production of wool in

Michigan and the best methods of improving this industry are treated of, the discussion being based in part on replies received to questions addressed to a number of wool dealers in different parts of the United States. Some of the principal deductions follow:

"Mutton growing with wool as an incidental product will continue to be a profitable industry. . . . Breed and feed affect the value of wool from the manufacturer's standpoint. Indiscriminate crossing is unprofitable. A sheep poorly nourished can not produce a healthy fleece. The manufacturer buys wool on the basis of its true value for manufacturing purposes. The grower, the local dealer, the commission man, and the scourer should each make an honest effort to satisfy his reasonable demands. . . .

"A small linen, or flax, or hemp twine is best for tying wool. . . . Coarse heavy paint marks should be avoided in marking sheep. More and better wool can be secured by early shearing. Loose, bulky fleeces sell best in the market. Country wool buyers can greatly aid in an effort to bring Michigan wools up to the standard by buying wool on its merits. By offering an advance in price for wools properly grown and prepared for the market, and by discriminating against poorly grown, dirty, or poorly tied fleeces. . . . Avoid lime and sulphur as a sheep dip."

Sheep in the coastal district, G. VALDAR (*Agr. Gaz. New South Wales*, 11 (1900), No. 1, pp. 38-44, pls. 3).—On the basis of trials at the College Farm and the testimony of a number of sheep raisers, different breeds suitable for the coastal region of New South Wales are suggested. The value of different cereal crops, grasses, leguminous crops, rape, and other crucifers for sheep feeding is discussed and a feeding experiment at the Hawkesbury Agricultural College briefly reported. Thirty Romney sheep and 8 Shropshire lambs were hurdled on $\frac{1}{4}$ acre of paspalum grass. After this was eaten, they were moved to a half-acre plat of white mustard and from this to an acre of rape. The test began June 22 and closed August 1. During this time the Romney lambs had gained 20 $\frac{1}{4}$ lbs. each and the Shropshires 30 lbs. Estimating the gain to be worth 3 cts. per pound, according to the author there would be a profit of \$25.72 from the 1 $\frac{3}{4}$ acres on which the sheep were pastured. It should also be remembered that the droppings of the sheep were valuable manure and that there was no expense in harvesting the crop, and that probably a second and even a third crop could be obtained from the rape and mustard, while the paspalum is a perennial grass.

Animal food for poultry, W. P. WHEELER (*New York State Bul.* 171, pp. 461-506, pl. 1).—In continuation of previous work (E. S. R., 11, p. 276), 2 series of tests are reported with chickens, hens, and ducks on the comparative value of vegetable and animal food, the latter ration being supplemented in the second test by bone ash. In the first series 5 lots of from 23 to 51 chickens 1 week old at the beginning of the test were fed the ration containing the animal food, which was made up of corn meal, animal meal, ground grain, gluten meal, etc. Five similar lots were fed the vegetable ration, consisting of wheat, barley, oats, and a mixture of several grains and concentrated

feeds. In addition all the lots were fed green alfalfa, oyster shells, and grit. The composition of the feeding stuffs used in this and the following test is reported, as well as the amount of feed consumed, the gain in weight, and similar data. A number of chickens were removed from the different lots during the test. At the close of the test, which covered 8 to 16½ weeks, the average weight of the chickens fed the ration containing animal food was 2.46 lbs., of those fed the vegetable food 1.94 lbs., 23 per cent more food being required per pound of gain by the latter.

The 2 rations were tested with 2 lots of some 26 Pekin ducks 1 week old at the beginning of the test, which covered 10 weeks. After the first month the ration fed lot 2 (vegetable food) was changed, as it was evident that it "was very deficient in some respect, for before the end of the fourth week one-half of all the birds in lot 2 had died." For 2 weeks animal meal was added to the feed and then the original ration was resumed. Only 1 duck died after the change. At the close of the test the average weight of the ducklings fed animal meal throughout the test was 5.9 lbs., of those fed the contrasted ration 5.5 lbs., 2.6 lbs. of dry matter being required per pound of gain with the former lot and 6 lbs. with the latter. The cost of a pound of gain in the 2 lots was 2.7 and 10.1 cts., respectively. It is said that the principal advantage of animal food was rapid growth and early maturity, rather than ultimate size.

Four lots of 11 and 15 pullets were fed the contrasted ration for about 200 days. The lots fed the ration containing animal food produced more eggs than those fed the vegetable food and less dry matter was required per pound of egg. The relative fertility of the eggs from the hens fed the different rations was also tested. In general the more fertile eggs were obtained from the lots fed the animal food. This point was further tested with 2 lots of two-year-old hens fed the contrasted ration. Little difference was found in the character of the eggs.

The second series of tests was made under conditions similar to those mentioned above, except that the ration of vegetable food was supplemented by bone ash, the object being to learn whether the small gains made on vegetable food were due to a deficiency in the ash constituents. As finally agreed upon, the contrasted rations had practically the same proximate composition. Six lots of from 61 to 99 chickens 1 week old at the beginning of the test were fed for 11 weeks. The average weight of the chickens fed the contrasted rations was practically the same at the close of the test, ranging from 1.1 to 1.7 lbs. In every case the chickens fed the ration containing the animal food required on an average about 13 per cent more food per pound of gain.

The 2 rations were further tested with 2 lots of about 30 Pekin ducks a little over a week old at the beginning of the test, which covered 9

weeks. The average gain of the ducks fed animal food was 5.3 lbs., of those fed vegetable food and bone ash 3.3 lbs., 3.3 lbs. of food, costing 8.5 cts., and 4.3 lbs. costing 4.1 cts. being required per pound of gain, respectively. Two lots of about 14 laying hens were used for further testing the 2 rations. The test covered 210 days. The average egg production of the hens fed animal food was 119.4 eggs; of those fed vegetable food and bone ash, 112.7 eggs, the dry matter required per pound of eggs being 3 and 3.2 lbs., respectively. The cost of food per pound of eggs was 3.2 cts. for each lot. When tested for fertility the eggs from the former lot were, in the author's opinion, better from a breeder's standpoint. No difference, however, in the vigor of the chickens hatched from the eggs of the 2 lots was observed. The author summarizes his experiments and the deductions drawn from them as follows:

"In general, rations containing animal food appear more palatable than rations of somewhat similar chemical composition consisting wholly of vegetable food. Rations in which the lack of palatability was overcome by using an unusual variety of grain foods were inferior for growing chicks and laying hens and decidedly inferior for ducklings to rations in which nearly one-fifth of the dry matter was supplied by animal food. After the period of most rapid growth had passed and the young birds approached maturity the difference in the efficiency between such rations rapidly disappeared. . . .

"Although it was found possible, when using a large number of foods in contrasted rations of these kinds, to have the ordinary groups of organic compounds in approximately equal proportions, there was always a much larger amount of mineral matter in the one ration owing to the bone of the animal meal. So there was sometimes nearly three times as much phosphorus in the one ration as in the other. . . .

"From these results it appears that rations containing a necessary amount of protein and having the relation of the ordinarily considered constituents satisfactory may be inferior because of a lack of mineral matter, probably phosphates.

"Not enough data are now available to show to just what extent the deficiency of lime in the food for the younger chicks may have been responsible for inferior results. With laying hens lack of lime could not have affected the results considered, for oyster shells were freely supplied, and it has been shown that such material can make good the frequent deficiency of lime.

"It appears also that while a cheaper vegetable food ration can sometimes be made to equal or surpass in efficiency a ration containing animal food by supplementing it with suitable mineral matter, there are plain limitations to its economical use. For laying hens some animal food appears necessary for continued good results. Ducklings without an abundant supply of animal protein in the ration, together with a liberal proportion of mineral matter, seem unable to make any approximation to their normally rapid and most profitable growth.

"Although bone ash was used to make good an assumed deficiency in one ration and proved an efficient addition for the purpose, it should not be inferred that its purchase for feeding is to be generally recommended. It was necessarily used to obtain information. Bone ash in the market is expensive. The same amount of mineral matter can be obtained much cheaper in fresh bone or animal meal, of which food it constitutes an important part. In some instances, of course, dry bones, where no facilities exist for grinding, or green bones in questionable condition, can be safely and economically used when charred or reduced to ash. The very desirable organic matter associated with fresh or cooked bones should not be wasted."

Poultry experiments, W. P. BROOKS and H. M. THOMSON (*Massachusetts Hatch Sta. Rpt. 1899*, pp. 49-55).—The value for egg production of rations with wide and narrow nutritive ratios was tested in the winter and summer. In each case 2 lots of 20 White Wyandottes and 2 lots of 20 Barred Plymouth Rocks were used. The principal grain in the ration with the narrow nutritive ratio was wheat, and in the ration with the wide nutritive ratio corn. Therefore the tests are in effect a comparison of these two grains for laying poultry, supplemented by a variety of other food.

The winter experiment began October 25 and closed April 27. The summer experiment began May 1 and closed September 27.

The authors summarize the results of the tests as follows: "Our results with both breeds, both summer and winter, are greatly in favor of the ration richer in corn meal and corn. On its side we have (1) lower cost of feed, (2) from 23 to 91 per cent more eggs, (3) a far lower cost per egg, making possible a saving of from $4\frac{2}{3}$ to $16\frac{3}{4}$ cts. per dozen in the food cost of their production, (4) a greater increase in weight, and (5) a much earlier molt."

It was the intention to test the wide and narrow rations with Black Minorca pullets, but this test was discontinued owing to roup. The results are not given in detail. "The test with this breed was not . . . at all conclusive. . . . Up to the time the test was closed, however, the corn-fed Minorcas had laid about 50 per cent more eggs than the others."

Erroneous ideas regarding food value, H. SNYDER (*Sanitary Home*, 2 (1900), No. 3, pp. 53-55).—The author points out a number of widespread popular errors concerning potatoes, mushrooms, white wheat flour, white and yellow corn meal, etc.

Domestic science in agricultural colleges, JUNIATA L. SHEPPARD (*Amer. Kitchen Mag.*, 12 (1900), No. 5, pp. 177-179, fig. 1).—A descriptive and statistical article.

Handbook of domestic science and household arts, LUCY L. W. WILSON (*New York and London: The Macmillan Company, 1900*, pp. XIII+407, ill.).—This is a textbook giving concise directions for lessons on food and nutrition, cooking and serving food, cleaning, household pests, and other topics generally included under the term domestic science. The chapters are contributed by a number of different writers.

Bread and the principles of bread making, HELEN W. ATWATER (*U. S. Dept. Agr., Farmers' Bulletin 112*, pp. 38, figs. 3).—The cereal grains and the flours made from them are discussed, as well as yeast, the theory of fermentation, bread raised with yeast and with leaven, special breads, household and bakery methods of bread making, chemical composition of bread, imperfections and impurities, nutritive value as related to cost, and similar topics.

Samples examined by the station (*Connecticut State Sta. Rpt. 1899*, pt. 2, pp. 93-100).—The Connecticut Pure Food law and the law regarding commercial feeding stuffs are quoted and brief statements made concerning the foods and condiments analyzed by the station. These include 149 samples of coffee, 2 of coffee substitutes, 92 of soda-water sirup, 23 of bottled sirup, 5 of fruit juice, 90 of bottled carbonated drinks, 2 of peanut butter, 31 of food preservatives, 2 of borax, 3 of banana flour, 2 of butter and imitation butter, 213 of molasses and sirup, 45 of vinegar, 2 of honey, and 43 of milk and cream.

Food products examined for the dairy commissioner in the twelve months ended July 31, 1899 (*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 157, 158*).—Brief statements are made concerning the samples of butter, molasses, honey, etc., examined.

Contribution to the study of slimy bread, A. JUCKANACK (*Ztschr. Analyt. Chem., 39 (1900), No. 2, pp. 73-81*).—The bacterial origin of slimy bread is discussed, many investigations being cited.

Vegetable cheese, C. F. LANGWORTHY (*Sanitary Home, 2 (1900), No. 3, pp. 55-57*).—A popular article describing the bean cheese or bean curd and other food products made in the Orient from soy beans.

The chemical composition of authentic samples of spices and spice adulterants, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 100-105*).—Details are given of the analyses of pepper and other spices under the Connecticut pure food law.

Coffee, A. L. WINTON (*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 106-111*).—Analyses of a number of samples of coffee under the Connecticut pure food law are reported. A marked decrease was observed during the year over the samples of adulterated coffee found in the previous year. The author believes this is due to the work of the station.

Carbonated, non-alcoholic beverages ("temperance drinks," "summer drinks") and fruit flavors, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 112-137*).—Soda water, bottled carbonated beverages, and sirups are described, and the analyses of a large number of samples in accordance with the Connecticut pure food law are reported. Many of these contained coal-tar colors, artificial flavoring, and such preservatives as salicylic and boric acids.

Peanut butter and peanolia, A. L. WINTON (*Connecticut State Sta. Rpt. 1899, pt. 2, p. 138*).—Analyses of 2 samples of peanut butter are reported.

Composition of banana and plantain fruits (*Bul. Bot. Dept. Jamaica, n. ser., 7 (1900), No. 2, pp. 24-30*).—A partial reprint of an earlier publication.¹ The composition of green and ripe fruit and banana flour is quoted. The chemical and other analytical work on bananas and plantains of a number of investigators is summarized.

Banana flour, vinegar, milk, and cream (*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 156, 157*).—Samples of banana flour, vinegar, milk, and cream were analyzed. It is stated that banana flour is prepared from the dried flesh of the fruit. The composition of the different sorts of banana flour follows:

Composition of banana flour of different sorts.

	Water.	Protein.	Fat.	Nitrogen-free extract.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Flour from—					
Porto Rico bananas	13.43	3.50	0.47	79.82	2.24
Florida bananas	5.34	2.81	.66	87.45	2.90
Honduras bananas	10.33	2.87	.50	87.02	2.55

The use of chemicals for preserving food, M. GRUBER (*Oesterr. Chem. Ztg., 3 (1900), No. 4, p. 84*).—The legal situation regarding added food preservatives in Austria is treated of.

The use of added preservatives, T. SMITH (*New England Kitchen Mag., 12 (1900), No. 4, pp. 127-129*).—The author discusses the properties and methods of detection of a number of the more common food preservatives.

Chemical preservatives, E. H. JENKINS, W. L. MITCHELL and A. W. OGDEN

¹ Bul. Misc. Infor. Roy. Garden Kew, 1894, pp. 305-310.

(*Connecticut State Sta. Rpt. 1899, pt. 2, pp. 139-152*).—A large number of preservatives for milk, cream, wine, cider, and beer were examined.

"[According to the authors, their work] shows that milk and cream preservatives now on the market depend for their antiseptic effects on salt, formaldehyde, borax, and boric acid; and that if the directions given by the manufacturers are followed, a quart of milk will be dosed with from 0.01 to 0.05 gm. of formaldehyde or with 0.47 to 3.6 gm. of boric acid. Cream will receive from 0.94 to 5 gm. of boric acid per quart.

"Wine and cider preservatives have been found to contain formaldehyde, salicylic acid, boric acid, benzoic acid, and betanaphthol. The cider, treated as directed by the manufacturers of the preservatives, may contain 0.36 to 0.9 gm. of salicylic acid or 0.19 to 0.38 gm. of borax or 0.6 to 0.7 gm. of benzoate of soda per quart. The beer preservatives contain salicylic acid and sulphurous acid in form of sulphites or bisulphites, and beer treated with them may contain from 0.04 to 0.12 gm. of salicylic acid or 0.015 gm. per half-liter glass. Of sulphurous acid, preserved beer may contain 0.015 gm. per half-liter glass."

Report of the chemist (division of foods and feeding), J. B. LINDSEY ET AL. (*Massachusetts Hatch Sta. Rpt. 1899, pp. 103-107*).—This is a brief general account of the work of the chemical laboratory during the year, which included the examination of samples of water, dairy products, and feeding stuffs. Short notes are also given on feeding experiments and dairy studies, and on digestion experiments which are being conducted at the station.

Concentrated feed stuffs, J. B. LINDSEY ET AL. (*Massachusetts Hatch Sta. Bul. 64, pp. 31*).—A classification of concentrated feeding stuffs is suggested, and the analysis reported of a large number of samples of concentrated feeding stuffs, made in compliance with the Massachusetts law. The constituents determined were moisture, protein, and fat. The materials analyzed include cotton-seed meals, linseed meals, gluten meals and feeds, wheat middlings, mixed feed, wheat bran and shorts, cereal food by-products, brewers' grains, malt sprouts, Sucrene Dairy Feed, Blatchford calf meal, corn meal, hominy meal, oat feed, corn-and-oat feed, corn-oat-and-barley feed, Kafir corn, corn screenings, chop feed, shredded wheat, ground oats, barley meal, rye feed, rye meal, Marsden's new food product (ground corn shives), concentrated food, poultry feeds, scratching food, scratching grain, clover meal, cut clover, and meat and bone meal.

The standards adopted for the different concentrated feeds are quoted. The results of the analyses are discussed as follows:

"(1) The cotton-seed meals shipped into Massachusetts the past year were practically free from adulteration, yet the guaranteed meals averaged 1 per cent higher in protein, showing the advisability of buying only branded goods. The guaranty in all cases should be supported by the name of the manufacturer or wholesaler.

"Last spring several samples of dark-colored meal were taken by our inspectors, and a number of others were sent in for examination, which, upon analysis, gave a high percentage of protein, proving that color alone is not a safe guide.

"(2) Cleveland flax meal, old process and new process linseed meals, gluten meals, and gluten feeds are of fair average composition with the exception of the old process linseed meals, which are low in many cases.

"(3) Of the wheat feeds, the middlings show quite a wide variation in percentage of protein as a result of different methods of manufacture; the mixed feeds with few exceptions are of fair quality, and the brans are of a high and very uniform grade.

"(4) The oat feeds show the most serious adulteration of any feeds on the market. Many of them fall below 7 per cent in protein with an average of 45 per cent of coarse material."

Concentrated feeding stuffs, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt. 1899*, pp. 139-143).—The text of the Vermont law regulating the sale of concentrated feeding stuffs is quoted, and analyses made in compliance with this law are reported. The materials analyzed include cotton-seed meal, gluten meals and feed, cocoanut fiber feed, calf meal, middlings, cereal food by-products, horse feed, hen feed, corn and oats, chop feed, and ground rape seed. Some of the feeding stuffs are briefly discussed.

Commercial feeding stuffs, E. H. JENKINS ET AL. (*Connecticut State Sta. Rpt. 1899*, pt. 2, pp. 159-196).—A reprint of the analytical matter of Bulletin 130 of the station (E. S. R., 12, p. 70), with a discussion of the composition and uses of commercial feeding stuffs.

Feeding stuff inspection, H. J. WHEELER and B. L. HARTWELL (*Rhode Island Sta. Bul. 63*, pp. 91-100).—The text of the Rhode Island legislation regulating the sale of concentrated commercial feeding stuffs is quoted and the analyses reported of a number of samples of feeding stuffs in accordance with this act. The constituents determined were protein and fat. The analyses include American Poultry Food, Poultry Food, gluten meals, linseed meals and feed, old process oil meal, cotton-seed meal, barley sprouts, chop, Sucrene Dairy Feed, corn-oat-and-barley feed, provender, stock feed, oat feed, Fancy Feed Meal, Sugar Corn Feed, and barley feed.

On the composition and food value of mammals, birds, and reptiles, BAL-
LAND (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 8, pp. 531-533).—Several analyses are quoted and reference made to earlier work.

Food value of oak moss, J. H. BARBER (*Pacific Rural Press*, 59 (1900), No. 13, p. 197).—Oak moss (*Ramalina reticulata*) is sometimes used as a cattle food. According to an analysis by M. E. Jaffa of the California Experiment Station, it has the following percentage composition: Water, 22.29; protein, 9.15; fat, 1.95; nitrogen-free extract, 48.37; crude fiber, 13.77; and ash, 4.5.

Food value of tall tarweed (*Pacific Rural Press*, 59 (1900), No. 13, 197).—The food value of tall tarweed (*Centromadia pungens*) is discussed and an analysis by M. E. Jaffa of the California Experiment Station briefly reported. The protein content was found to be 12.3 per cent and the fuel value 919 calories per pound.

Experiments on the digestive power of pigs, LILIENTHAL (*Landw. Wehnl. Schleswig-Holstein*, 50 (1900), No. 5, pp. 81-89).—A comparison of the digestibility of different rations by several breeds of pigs, including Yorkshires, Berkshires, Holsteins and "Marschschwein." The latter is a breed very closely related to the European wild hog.

Cost of wintering beef herd, E. R. LLOYD (*Mississippi Sta. Rpt. 1899*, p. 14).—A summary of data given in Bulletin 60 of the station (E. S. R., 11, p. 1084).

Beef herd, E. R. LLOYD (*Mississippi Sta. Rpt. 1899*, pp. 14, 15).—A study is being made of the relative merits of native and grade Angus cattle for beef production. The average weights at birth and each month for 8 months of calves of the 2 breeds are tabulated.

Feeding tests to determine the relative value of corn, cotton seed, and cotton-seed meal for beef production, E. R. LLOYD (*Mississippi Sta. Rpt. 1899*, pp. 13, 14).—A summary of the results of feeding experiments previously reported (E. S. R., 11, p. 1068).

Milk substitute for calves, A. CRAWFORD (*Jour. Dept. Agr. West. Australia*, 1900, Feb., p. 17).—Oil cake and oatmeal 1: 1 cooked, mixed with hay tea and a little milk, is recommended as a useful food for calves. The oil cake should be increased as the calf grows older.

What grains lack as poultry foods, F. H. HALL and W. P. WHEELER (*New York State Sta. Bul. 171*, popular ed., pp. 6).—This is a popular summary of Bulletin 171 of the station (see p. 276).

DAIRY FARMING—DAIRYING.

Feeding tests and their methods, J. L. HILLS (*Vermont Sta. Rpt. 1899, pp. 252-296, 310-351*).—Experiments, partly in continuation of work previously reported (E. S. R., 11, p. 382), were made to compare various rations and to test different feeding stuffs, to determine the effect of feeding liquid fat to cows, to compare methods of watering cows, to test the effect of grooming on production, and to determine the extent of experimental error in feeding tests. Fifty-six cows in all were used in the series of experiments which lasted from October 25 to June 6. Each experiment covered 4 or 5 weeks, one-third of which was considered preliminary. The number of cows used in the different tests varied from 1 to 14. In addition to hay and silage, and in some cases sugar beets or artichokes, the following mixed feeds were employed: (1) Cotton-seed meal, linseed meal, corn meal, and wheat bran (3:3:4:6); (2) cotton-seed meal, linseed meal, corn meal, and wheat bran ($3\frac{1}{2}$: $3\frac{1}{2}$:3:6); (3) buckwheat middlings, corn meal, and wheat bran (4:1:3); (4) equal parts of corn meal and wheat bran; and (5) corn meal and wheat bran (8:4). Eighteen different rations were fed.

Tables give complete data for the experiments, including weights of cows, barn temperatures, analyses, and digestible ingredients of the fodders and feeds, records of the individual cows, and results of experimental feeding on different rations. The author summarizes the details and results of the investigation as follows:

“*The relative feeding values of rations of equal balance.*—(a) *Medium nutritive ratios.*—The fodders and feeds used were hay, silage, and Buffalo gluten feed—nutritive ratio averaging 1:5.7, and the same roughages with mixed feed No. 1—nutritive ratio averaging 1:5.6. The former ration yielded to the unit of total dry matter eaten from 4 to 5 per cent greater product, and the quality of the milk remained unchanged.

“(b) *Wide nutritive ratios.*—The fodders and feeds used were hay, silage, and corn and bran, and the same roughages with Quaker oat feed—nutritive ratio in each case averaging 1:8.9. The former ratio yielded to the unit of total dry matter eaten from 2 to 3 per cent greater product, the quality of the milk remaining uniform.

“In the one case production to the unit slightly favored the ration which was fed the more liberally; in the other case 2 rations equally balanced and containing the same amounts of the sundry nutrients were of equal feeding value. The outcome of 3 years’ trials of this kind indicates that uniform production is not to be expected of necessity when there are eaten equal amounts of digestible nutrients derived from diverse sources.

“*The effect of adding raw or emulsified fat to a ration.*—Unemulsified cotton-seed oil and emulsified cotton seed, corn, and linseed oils were fed with bran or corn meal and bran, hay, and silage, as against the same rations without the oil. Milk yields to the unit of dry matter eaten were always increased when oil was fed, the increase amounting from 3 to 9 per cent. The amount of total solids and fat were increased by the cotton-seed oil feeding from 2 to 15 per cent, on linseed oil feeding 2 per cent, and on corn oil feeding not at all. The quality of milk was always improved at the outset of this class of feeding, but quickly returned to normal quality or became poorer than usual when corn or linseed oils were fed. The increased fat percentage—unaccompanied by rise in the percentage of solids-not-fat—was fairly permanent,

lasting from 4 to 6 weeks at least, when either raw or emulsified cotton-seed oil was used. Since the same changes were brought about when raw oil was fed as followed the use of emulsified oil, it is safe to say that in these trials emulsifying was without influence as a means of feeding fat into milk.

"*The feeding values of medium and wide rations.*—(a) *Grain rations equal in amount.*—The fodders and feeds used were hay, silage, and mixed feed No. 1, or the same roughages and Quaker oat feed. Nutritive ratios averaged 1:5.8 and 1:9.0. The producing power of a unit of dry matter was 7 per cent greater in the former ration. The fat content of the quality of the milk remained essentially unchanged.

"(b) *Grain rations unequal in amount.*—The fodders and feeds used were hay, silage, and 8 lbs. of Buffalo gluten feed, or the same roughages with 2 lbs. of corn meal and 1 lb. of bran. Nutritive ratios averaged 1:5.5 and 1:9.7. The unit of dry matter eaten in the medium ration made 5 per cent more milk than did that in the wide ration. Less but richer milk seemed to be produced by the scant ration.

"*The feeding value of buckwheat middlings.*—The fodders and feeds used were hay, silage, corn meal, bran, and buckwheat middlings, the same roughages with mixed feed No. 1 or corn meal and bran. A unit of dry matter eaten produced about 3 per cent more milk, solids, and fat in ration No. 1, and about 4 per cent less in the corn and bran ration than when the middlings were fed. The quality of the milk remained generally uniform, with, however, two exceptions.

"*The feeding value of artichokes.*—Hay, silage, and mixed feed No. 1, or hay, artichoke tubers and mixed feed No. 1 were fed to one cow. To the unit of dry matter eaten 10 per cent less milk was made on the silage ration.

"*Watering at will or at intervals.*—Cows fed a uniform ration were in alternating periods watered at will or at intervals, and in the former case made 2 per cent more milk. The effect upon quality can not be stated for reasons given in the body of the article.

"*The grooming of cows.*—Cows fed a uniform ration were in alternating periods groomed or left uncared without appreciable effect either upon milk yield or quality.

"*Experimental error.*—Uniform rations were fed and uniform production ensued. A unit of dry matter made essentially the same milk, solids, and fat at one time as another, lactation changes being equalized. It is probably unsafe to lay stress on apparent differences in feeding values of much less than 5 per cent.

"*Relative values of various grain rations.*—Assuming that two-thirds of the manurial ingredients reach the soil, and allowing 20 cts. per hundred for skim milk, the total and the daily net gains of one ration over another in butter, skim milk, and manure, expressed in dollars and cents, are as shown in the table. In each case the ration first mentioned proved superior to its competitor:

Relative superiority of different rations.

Ration.	Days of feeding one cow.	Net gain from butter.	Net gain from butter, skim milk, and manure.	Daily net gain, one cow.
				<i>Cents.</i>
Buffalo gluten ration v. cotton-seed-linseed ration	529	\$4.61	\$6.05	1.14
Buffalo gluten ration v. ration of 2 parts corn, 1 part bran....	276	-4.18	3.86	1.40
Cotton-seed-linseed ration v. Quaker oat feed ration	118	0.45	3.12	2.64
Corn and bran ration v. Quaker oat feed ration	118	0.00	0.75	.64
Cotton-seed-linseed ration v. buckwheat middlings ration ...	128	-0.72	-0.02	.60
Buckwheat middlings ration v. ration of corn and bran.....	72	0.92	1.14	1.58

"The Buffalo [gluten] ration proved superior to the others, the cotton-seed-linseed ration ranking second."

The effect of fatigue upon the quantity and quality of milk, J. L. HILLS (*Vermont Sta. Rpt. 1899, p. 309*).—In this test, which is the third reported by the station (E. S. R., 8, p. 86; 11 p. 384), 6 fresh milch cows were driven 10 miles and shipped 50 miles by rail. They were not milked during the 18 hours occupied in traveling. A table gives the yield and composition of the milk one day, one week, and three weeks after arrival. The results are briefly discussed and compared with those of the earlier experiments.

"The cows, as a whole, gave about the same quantity of milk on the day after arrival that they did later. Its quality was far richer, however, at first than it was after some time had elapsed. Considering each animal individually it was found that three gave more, one less, and two the same yield after becoming accustomed to their new quarters; that the fat percentages were less in each case; and that the solids-not-fat were irregular, two increasing and one decreasing decidedly as time went on. . . .

"In the trials previously reported temporary milk shrinkage was observed. This was not seen to any great extent in the present tests. In all cases, as in the present instance, temporary enrichment ensued. The outcome of this series of tests clearly shows the folly of testing a cow's milk before she becomes 'at home' in new quarters and has recovered from fatigue."

The effect of food upon the quality of butter, J. L. HILLS (*Vermont Sta. Rpt. 1899, pp. 296-298*).—In connection with experiments noted above and in continuation of previous work (E. S. R., 11, p. 385) a study was made of the effect of various concentrated feeding stuffs upon the quality of butter. The rations used contained hay and silage with cotton-seed meal, linseed meal, corn meal, and bran in two combinations; corn meal and bran in two combinations; corn meal, bran, and buckwheat middlings; Buffalo gluten feed; and Quaker oat feed. Cotton-seed oil, corn oil, and linseed oil in emulsions were also fed with the corn meal and bran ration. From March 8 to May 1, 44 samples of skim milk, buttermilk, and butter were obtained and analyzed. The results are given in tabular form.

The author states that apparently none of the grain feeds injuriously affected the quality of the butter.

"Volatile acids were uniformly and decidedly lowered, and the iodine numbers markedly increased in every case when oil was fed and for a while after its use was abandoned. This was more apparent when corn and linseed oils were fed than when the cotton-seed oil was used. The melting point of the product made when the latter oil was fed was raised. . . .

"The station dairyman's judgment of these butters was that the cotton-seed product was hard and of quite good flavor, that made on linseed oil was very soft and sticky and of an oily taste—a condition lasting until the second sample after the use of oil was discontinued—while that made on corn oil was somewhat soft and oily but fair in quality. . . .

"While it is unsafe with our present lack of knowledge concerning the methods of milk formation to assert actual transfer from food to milk, yet analytical results and practical experience are in accord with such a theory."

Milk from cows fed cotton-seed oil skimmed and churned more exhaustively than that from cows fed linseed oil or corn oil.

Record of the station herd for 1897-98, J. L. HILLS (*Vermont Sta. Rpt. 1899, pp. 299-307*).—The record of 42 cows from November 1, 1897, to October 31, 1898, is given in tabular form and compared with records of the station herd during previous years, as already reported (*E. S. R.*, 11, p. 383). The data given include the production of milk, fat, and solids by each cow, the cost of food eaten, proceeds from butter sales, and the value of the fertilizing ingredients in the food fed. Notes are given explanatory of the table. The average proceeds per cow over the total cost of food for the year was \$34.15. The record of 19 of the cows belonging to the herd for 4 years and 24 for 3 years is summarized in the following table:

Average record of 19 cows for 4 years and 24 cows for 3 years.

	Yield of milk.	Fat content of milk.	Yield of butter.	Cost of food.	Cost of purchased grain.	Cost of food per pound of butter.	Proceeds of butter sales.
	<i>Pounds.</i>	<i>Per cent.</i>	<i>Pounds.</i>			<i>Cents.</i>	
Average of 19 cows:							
1894-95.....	5,864	4.94	338	\$53.16	\$19.92	17.6	\$79.30
1895-96.....	5,927	5.01	347	43.54	14.75	13.5	79.77
1896-97.....	6,475	4.87	368	49.77	19.26	14.0	89.24
1897-98.....	5,631	4.95	318	46.54	15.48	15.1	81.85
Average of 24 cows:							
1895-96.....	5,657	5.12	338	42.56	14.45	13.3	77.76
1896-97.....	6,012	5.04	354	48.66	18.98	13.8	85.80
1897-98.....	5,698	5.00	325	46.98	15.71	15.0	83.69

Laws of the composition of cows' milk, and the detection of adulteration, H. TIMPE (*Chem. Ztg.*, 23 (1899), No. 99, pp. 1040-1043).—The author attempts to trace a relation between the protein and the fat. He shows, with the aid of a series of analyses of the milk from cows of different breeds, arranged in the order of fat content, that the range in protein content is only about one-third of that in fat content, and accordingly that the fat increases in the series about three times as fast as the protein. In the case of milk containing an average fat content of about 3 per cent the protein was about the same, but when the fat was lower than this the protein exceeded the fat; and when the fat was above 3 per cent the reverse was true. The author deduces the following formula for protein: Protein = $2 + 0.35 \text{ fat}$. He advances the hypothesis that the fat and a part of the protein are of common origin, being derived probably from the splitting up of the same basal material, while the rest of the protein is formed independently of the fat. This would indicate two kinds of protein in the milk. The part derived from the same source as the fat has a constant value of 2. Indicating this as protein *a*, and the other portion as protein *b*, the ash, sugar, and protein *a* may be regarded as practically constant in milk, while the fat and protein *b* are subject to wide variations. The last two bear a definite relation to each other, protein *b* being equal to 0.35 of the fat.

These generalizations were verified on milk from cows of different

kinds, in health and disease, and fed different rations. In milk from healthy cows there was only one case in which the protein did not bear the normal relation to the fat. The sugar content was found remarkably constant, fluctuating only from 4.4 to 5 per cent.

These regularities in the composition of milk are thought to furnish a reliable means for detecting adulteration. In skim milk the protein, as calculated by the above formula, will be lower than that found by analysis, while the ash and sugar will be normal. Water would lower the content of all the constituents without changing their relation to one another, but it would depress both the protein *a* and protein *b*, so that the total protein calculated by the formula would be higher than that found by analysis. The sugar content would be another indication of watering. Skimming and watering the same sample is somewhat more difficult to detect by this method, but unless both had been practiced to the same degree the disturbance of the relation between the fat and protein would be apparent.

In a later issue of the same journal (24 (1900), No. 3, p. 16) H. Höft discusses the above paper and takes exception to some of the conclusions.

The efficiency of a continuous pasteurizer at different temperatures, H. A. HARDING and L. A. ROGERS (*New York State Sta. Bul.* 172, pp. 507-530, figs. 2).—Introductory statements are made concerning dairying in Denmark and in the United States. The lack of success attending the use by Americans of the Danish method of butter making has led the station to undertake a study of the process, the results of which are to be published in a series of bulletins, of which this is the first. The terms pasteurization and sterilization are explained, and the discontinuous or household system of pasteurization for sanitary purposes and the continuous or Danish system adapted to butter making are discussed.

In the experiments at the station "the objective point was to determine the effect upon the germ life when milk was passed through a continuous pasteurizer at different temperatures." Milk was pasteurized at 70, 80, and 85° C. The apparatus used was made in Denmark, and is figured and described. The method of work is given, and data showing the age, weight, initial temperature, and acidity of the milk, the steam pressure in the boiler, the rate of pasteurization, and the germ content of the milk before and after pasteurization are tabulated. The milk was usually a mixture of portions 4, 12, 24, and 36 hours old and had an acidity requiring from 18.9 to 40 cc. of normal alkali to neutralize 1 liter. The samples averaged 350 lbs. The rate of pasteurization varied greatly. At 80° C. it was about 2,100 lbs. per hour. In the bacteriological tests neutral lactose agar was used as a nutrient medium. The plate cultures were kept at 30° C. and the colonies were counted at the end of 48 hours.

Results of the work are summarized as follows:

"At 70° C. (158° F.) the efficiency of the continuous pasteurizer varies greatly from day to day. Tests upon 14 different days gave an average of 15,288 living germs per cubic centimeter left in the pasteurized milk, with a maximum of 62,790 and a minimum of 120 germs.

"At 80° C. (176° F.) the reduction in germ content is both very uniform and very great. Tests upon 25 different days gave an average of only 117 living germs per cubic centimeter in the pasteurized milk, with a maximum of 297 and a minimum of 20 germs.

"At 85° C. (185° F.) the average reduction is not more marked than at 80° C., but the range of variation is less. [The average, maximum, and minimum of tests made upon 7 different days were, respectively, 114, 234, and 50 germs per cubic centimeter.] This temperature has the added advantage, according to Dr. Bang, of removing the danger from germs of tuberculosis in the milk.

"Even when the whole milk was heated to 85° C. the butter did not have a permanent cooked flavor."

On the manufacture of cheese from pasteurized milk, G. HAMILTON (*Milch Ztg.*, 29 (1900), No. 10, pp. 145, 146).—Milk was pasteurized at 102° C. and used in the manufacture of sour-milk cheese and brick cheese. In making the sour-milk cheese 10 per cent of fresh buttermilk, obtained from churning cream ripened with a pure culture, was added to the pasteurized milk and the mixture kept at 30° C. until the required acidity was secured. Sour-milk cheese properly made in this way was considered better than that made from unpasteurized milk and the yield was also greater. Notes are given on the use of pasteurization in Saxony.

Dairy work, J. S. MOORE (*Mississippi Sta. Rpt.* 1899, pp. 22-28).—The results of feeding experiments with cotton seed, cotton-seed meal, and corn-and-cob meal, and a study of the effect of these feeding stuffs on the quality of butter previously reported (E. S. R., 11, pp. 1079, 1080) are summarized. Tables are given showing the amount and cost of food consumed and the milk and butter produced by each cow of the dairy herd during 1898. Tests of 7 registered Jersey cows are reported.

Feeding for milk (*Queensland Agr. Jour.*, 7 (1900), No. 1, pp. 25, 26).—During 2 periods of 15 days each 6 cows were fed a ration of 20 lbs. of green chaffed maize and during the second period were given in addition 1½ lbs. of molasses. Only a small increase in the yield of milk and butter followed the use of the molasses. The daily record of each cow is given.

The management of Shorthorn dairy cattle and young stock, R. E. TURNBULL (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), No. 2, pp. 83-92).

Heavy vs. light cows, G. H. V. SCHEELE (*Landtmannen*, 11 (1900), No. 4, pp. 52-57).

On the importance of good milkers, J. FRIIS (*Landmandsblad*, 33 (1900), No. 8, pp. 90-98).—A general discussion of the subject; a number of experiments are quoted, showing how the amount of milk yielded by cows varies according to the character of the work done by the milkers.

Milk test inspection law, C. H. JONES and B. O. WHITE (*Vermont Sta. Rpt.* 1899, pp. 143-145).—The text of the Vermont law relating to testing milk and cream at dividend-making creameries and cheese factories and the results of the operation of the law are given. The law requires that all glassware used in testing be certified as to its accuracy and that all operators be licensed after proving their ability. The

execution of the law is vested in the superintendent of the dairy school of the university.

Of 11,058 bottles tested during 9 months, 199 were found incorrectly graduated. A considerable number of pipettes and acid measures were also found incorrectly graduated. The effect of the passage of the law in increasing the accuracy of the apparatus used is noted. Of 286 applications for license as operators, 33 were refused because of inaccurate testing.

Continuous pasteurization of milk, F. H. HALL, H. A. HARDING, and L. A. ROGERS (*New York State Sta. Bul.* 172, popular ed., pp. 6).—This is a popular summary of Bulletin 172 of the station. (See p. 287).

Report of milk control station in Christiania for 1899 (*Norsk Landmandsblad*, 19 (1900), No. 6, pp. 68-70).—Tests of 39,158 samples of milk and other dairy products were made during 1899, the average results per month and year being given in the report. The average fat content for 33,831 samples of whole milk examined during the year was 3.473 per cent (maximum 5, minimum 2.5 per cent), and of 4,944 samples of cream 17.304 per cent ("common cream" testing between 11 and 24 per cent, and "whipping cream" from 25 to 38 per cent).—F. W. WOLL.

Report of the milk control station in Trondhjem, Norway, for 1899 (*Norsk Landmandsblad*, 19 (1900), No. 18, pp. 197-199).—During the year 55,292 samples of dairy products, nearly all whole milk, were received and tested. The average fat content of 55,162 samples of whole milk was 3.57 per cent, against 3.50 per cent for 46,473 samples during 1898. The report states that "as is usual, the milk is lowest in fat in the spring, because the majority of the cows drop their calves at this season. It is characteristic that the fat content of the milk increases suddenly when the cows are let out on pasture. This increase occurs every year in the month of June. The high fat content is maintained during July, or may drop again then, as was the case in 1895 and 1897. During the fall months the percentages of fat are gradually increased, to decrease again toward the end of the year." The fat contents of the milk tested at the milk control stations at Christiania and Bergen (at each of which stations a similar number of samples of milk are tested annually) show identical changes as those given above.—F. W. WOLL.

VETERINARY SCIENCE AND PRACTICE.

Fourteenth annual report of the State board of live stock commissioners, C. P. JOHNSON ET AL. (*Rpt. Illinois State Bd. Live Stock Commissioners*, 1899, pp. 391).—This report contains a
8058—No. 3—7

copy of the proclamation of the board of live stock commissioners of Illinois regarding the importation of Southern cattle. In their experiments with dips for the purpose of destroying the cattle tick on animals imported from the South some losses were experienced, but it is believed that such losses are due not so much to the dipping itself as to the fact that the dipping occurred at an inopportune time, or that the cattle were subjected to fatiguing drives or railroad journeys after the dipping. Detailed records are given of the inspection for actinomycosis at the Union Stock Yards of Chicago.

Special attention has been given by the board for a number of years to tuberculosis among dairy cattle. The regulations of the board provide that animals condemned and slaughtered after the tuberculin test shall be divided into 6 classes, for the purpose of adjusting the amount of indemnity to be paid the owner. Class A includes animals which upon *post-mortem* examination fail to disclose the presence of tuberculosis in any of their organs. For such animals the full valuation is paid as indemnity to the owner. The other classes are graded according to the more or less generalized condition of the tubercular infection, 75, 50, 35, 25, and 15 per cent of the appraisement being paid for animals in these classes. The number of animals tested was 3,655, and of this number 560 reacted sufficiently to warrant condemning, while 47 were isolated and held for a second test. The percentage of condemned animals was, therefore, 15.32.

The board made an investigation of the milk of a number of tuberculous animals, the milk being used for inoculating the experimental animals, and being also subjected to microscopical examination. The conclusions which are drawn from these examinations may be stated as follows: The tubercle bacillus is found in the milk of 35 per cent of tuberculous cows with sound udders. The tubercle bacillus is found with about equal frequency in the sediment and in the cream. The milk when concentrated produces tuberculosis in about 25 per cent of the inoculated guinea pigs. In a large number of cases pus cells were found in the milk, which would indicate that the udder was affected by tuberculosis. It is stated that in consideration of the greater susceptibility of the guinea pig, the concentration of the milk, and the fact that inoculations were made hypodermically, allowance must be made for the different conditions when these results are applied to the human subject.

Detailed notes are given on the occurrence in the State of glanders, cerebro-spinal meningitis of horses, and sheep scab. In an appendix to the report is found a complete record of the tuberculin tests already referred to.

Actinomycosis of man and animals, B. SCHÜRMAYER (*Centbl. Bakt. u. Par., 1. Abt., 27 (1900), Nos. 2, pp. 49-61; 3, pp. 101-106, pls. 2*).—This article contains a report of an extended series of experi-

ments by the author upon the variations in the organism of actinomycosis under different culture conditions. When this organism is cultivated in ordinary alkaline bouillon without peptone or salt, 3 morphologically distinct forms were observed: (1) Unbranched and branched filaments; (2) delicate threads with thickenings and without branches; (3) round large spheres. The second form was frequently seen to develop out of this third form.

Experimental cultures which were carried on for two years under the same conditions and with the same results led the author to conclude that the organism of actinomycosis may vary exceedingly as to its external appearance, has the power of adapting itself to the nutrient medium and external conditions, and passes through a series of stages, which include the bacterial type and reach to that of the higher fungi.

The organism is described by the author under the name of *Oospora proteus*. A detailed record is given of the appearance and behavior of the organism under different conditions and upon different culture media. The variations of this organism are compared with those of *Oospora bovis*. In some of the experimental cultures chlamydospores were formed, and the author believes that this and other pathogenic organisms will be found to be forms of a series which extends from bacteria into the higher fungi.

Tuberculosis of cattle, G. E. NESOM (*South Carolina Sta. Bul.* 50, pp. 41, figs. 10).—The first part of the bulletin is occupied with a general account of the nature and etiology of tuberculosis and a description of the method of applying the tuberculin test. A report is made on 200 cattle tested with tuberculin in the State. The cattle were distributed in 6 herds, and the presence of tuberculosis was demonstrated in only one herd. One doubtful case was found in the second herd. In one herd of 66 cattle, 61 of which were milch cows, 31 reacted. The veterinarian who had attended this herd had made a diagnosis of tuberculosis and had confirmed it by *post-mortem* examination. Of the animals in this herd 9 showed a temperature of 105° or more before injection, and 3 out of these 9 gave a reaction of over 2° after injection. The ages of the animals of this herd varied from 1 to 15 years. In the other herds which were tested only one animal was condemned as suspicious, and the *post-mortem* findings were not sufficient to make the diagnosis certain. The animal, however, was considered tuberculous. Out of 200 tested, therefore, 32 animals or 16 per cent were found tuberculous, 31 of these, as already indicated, being found in one herd.

In the treatment of tuberculous herds the author recommends that the Danish system of isolating suspicious animals be adopted. He further recommends a municipal inspection of meats and milk and the issuance of a license to dairymen only after all his milch cows have been tested.

Observations concerning the significance of streptococci in comparative pathology, V. A. MOORE (*Amer. Vet. Rev.*, 23 (1900), Nos. 10, pp. 687-697; 11, pp. 774-787; 12, pp. 849-860, figs. 14).—The author gives a brief review of the literature on streptococcus and an account of the systematic position of this genus. A bacteriological investigation was made of 4 cases of suppurative cellulitis of cows, in which the foot or leg was affected. Streptococcus was found to be present in all cases. Other cattle inoculated with pure cultures of these organisms developed the same symptoms. Rabbits which were inoculated with pure cultures died with septicæmia within 48 hours after inoculation.

Samples of milk were taken from 8 different cows which were suffering from mastitis. The milk samples were taken with strict antiseptic precautions. Streptococci were found in considerable numbers in 6 out of the 8 samples. In 2 cases of foot rot of sheep, a form of streptococcus was found which proved fatal to rabbits when inoculated hypodermically. A bacteriological investigation demonstrated the presence of streptococcus in the following diseases of the horse: Fistulous withers, poll evil, peritonitis, omphalophlebitis, septic pneumonia, strangles, and infectious pneumonia.

The author also made studies of distemper and rabies of the dog. Streptococcus was found to be present in cases of distemper but not in rabies. Brief notes are presented on the use and importance of anti-streptococcic serum.

The curability of glanders, J. McFADYEAN (*Jour. Comp. Path. and Ther.*, 13 (1900, No. 1, pp. 55-59).—The author conducted an experiment to determine the therapeutic action of mallein upon glanderous horses. A horse with clinical symptoms of farcy was tested with mallein on November 4, 1898, and reacted in a typical manner with elevation of temperature and swelling at the point of injection. The highest temperature recorded was 105.4°. On November 15 the horse received 6 cc. of mallein and after 15 hours exhibited a temperature of 105.8°. On November 26, 10 cc. of mallein was injected into the horse, with a consequent sharp temperature reaction. A dose of 20 cc. of mallein was administered on December 6 with similar results. Further injections were made on December 14, 20, 28, and January 13 with 40, 80, 100, and 120 cc. of mallein, respectively. On February 10 the horse was examined and the farcy lesions were found to be healed. The animal was tested with 1 cc. of mallein on the same date and failed to react. On March 27 a second dose of 1 cc. of mallein was given, with no temperature reaction. On April 6 the horse received 100 cc. of mallein with the result that the temperature rose to 103.8°. The same dose repeated on April 24 produced a temperature of 103°.

The horse was apparently cured of the original attack of glanders.

In order to determine whether the animal was also protected against subsequent infection, an inoculation of virulent glanders pus was given on June 13, 1899. On June 23 an injection of 1 cc. of mallein produced a typical reaction, and similar results were obtained by repeated injections on July 7 and 22.

The author concludes from the history of this case that glanders can apparently be cured by repeated large doses of mallein, but that animals thus treated are not protected against subsequent infections by the disease.

Recent investigations on the rôle of mosquitoes in spreading malaria, G. H. F. NUTTALL (*Centbl. Bakt. u. Par., 1. Abt., 27 (1900), No. 5, pp. 193-196; 6, pp. 218-225*).—This article is in continuation of previous compilations of the author on the same subject. The author reviews in a critical manner the literature of the subject, under the following heads: General literature, the influence of temperature on the development of the malaria parasites in Anopheles, the species of mosquito in which the different malaria parasites can develop, and the development of the æstivoautumnal parasite.

Purulent broncho-pneumonia of puerperal origin, G. MOUSSU (*Rev. Med. Vet., Paris, 8. ser., 7 (1900), No. 3, pp. 105-111*).—A study of a number of cases in which it was shown that there was a postpartum infection, with a localization of the disease in the lungs.

Review of Prof. Bang's work with contagious abortion, C. E. MARSHALL (*Michigan Sta. Spec. Bul. 13, pp. 8*).—An abstract of the work of Prof. Bang bearing on this subject.

Experimental studies on blackleg, E. LECLAINCHE and H. VALLÉE (*Compt. Rend. Soc. Biol. Paris, 52 (1900), No. 6, pp. 139, 140*).—The authors found that the presence of the toxin is indispensable to the manifestation of virulence. Great numbers of the spores may be introduced into susceptible organisms without producing any effects, provided all toxin is excluded. Animals which have received spores without toxin are not rendered immune.

Failure with Seraphthin in Austria, GEIST (*Berlin Tierärztl. Wechschr., 1900, No. 7, pp. 75-77*).—The author conducted experiments for the purpose of determining the value of this substance as a protective remedy against foot-and-mouth disease. Out of 120 animals which were inoculated with Seraphthin, 79, or 65.83 per cent, contracted the disease, while out of 99 animals which were not inoculated only 46, or 46.5 per cent, fell sick. The author believes this substance is worthless both as a curative agent and as a means of producing immunity.

Infectious mastitis in cows, K. WEBER (*Deut. Thierärztl. Wechschr., 8 (1900), No. 6, p. 47*).—In cases where this disease affects only one quadrant of the udder, a thorough treatment with drainage is sometimes successful, resulting in a complete sequestration of the infected part.

Relapse in milk fever, BRU (*Rev. Vet. Toulouse, 25 (1900), No. 3, pp. 166-170*).—A discussion of the symptoms of this disease, together with an account of cases in which a relapse took place after an apparent recovery.

Traumatic pericarditis in cattle, G. DE BRUIN (*Rev. Vet. Toulouse, 25 (1900), No. 3, pp. 141-155*).—The cause of this form of pericarditis is the penetration of the pericardium by some foreign body. Such penetration comes from the second stomach, which is separated from the pericardium only by the diaphragm, and at a point in the diaphragm which undergoes comparatively slight movements during respiration. The disease usually assumes a chronic form and is very seldom acute. The majority of cases are fatal. A bibliography on the subject is added to the article.

Staggers in sheep, M. J. CLEARY (*Irish Agr. Organization Soc. Leaflet 8*, pp. 2).—The author gives notes on the life history of *Cœnurus cerebralis*, and recommends the destruction of the heads of affected sheep in order to prevent the spreading of the disease.

Œstrus ovis, J. F. BUTTERFIELD (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 1, pp. 23, 24).—From a study of the habits of this insect in Pennsylvania, the author concludes that the eggs are deposited in the nostrils of sheep earlier in the season than has usually been supposed. The only successful remedy consisted in trephining and washing out with tepid water. Injections of solution of alum water in the nostrils seemed to be slightly effective.

Protective inoculation against hog cholera, H. JOST (*Deut. Thierärztl. Wchenschr.*, 8 (1900), No. 6, pp. 45-47).—Notes on the use of Susserin and on the occurrence of endocarditis in hog cholera.

Horse bots, R. HELMS (*Jour. Dept. Agr. West. Australia*, 1899, Dec., pp. 23-28, figs. 2).—An account of the life history, habits, and remedies to be used against *Gastrophilus nasalis*.

Inheritance of chronic roaring, A. LABAT (*Rev. Vet. Toulouse*, 25 (1900), No. 3, pp. 155-166).—The author presents a detailed discussion of the literature of the subject and shows from statistics that horses which are afflicted with roaring very frequently transmit a predisposition to this disease in their offspring.

A form of hemorrhagic septicæmia in ducks and chickens, A. RABIEAUX (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 6, pp. 141-143).—The pathogenic agent found in cases of this disease resembles that of chicken cholera. It is aerobic. Experiments indicate that the pigeon, rabbit, guinea pig, white rat, and dog, in addition to ducks and chickens, are susceptible to the disease.

Epizootic-parasitic gastritis of fowls, A. RABIEAUX (*Jour. Med. Vet. et Zootech.*, 5. ser., 4 (1900), pp. 16-20, fig. 1).—This disease, it is stated by the author, is caused by the presence of *Spiroptera nasuta* in the gizzard of fowls. Vermifugal treatment had very little effect, and the author recommends preventive remedies, such as cleanliness of the poultry quarters and careful destruction of infected fowls.

External parasites of poultry (*Farmers' Gaz.*, 59 (1900), No. 1, pp. 16, 17).—Notes on bird lice, with suggestion of remedies.

The gape worm (*Syngamus trachealis*), R. KLEE (*Deut. Thierärztl. Wchenschr.*, 7 (1899), No. 52, pp. 465-468, figs. 3).—The author gives a description of the worm and an account of its habits and life history. The remedies which are recommended by the author include the usual ones and also the intratracheal injection of 1 cc. of a 5 per cent aqueous solution of sodium salicylate. A brief discussion of the literature of the subject is given in connection with a bibliography of 32 titles.

The temperature of the common fowl, C. FÉRÉ (*Jour. Anat. et Physiol. Paris*, 35 (1899), No. 6, pp. 808-816).—A difference in the normal temperatures of the two sexes was noticed, as well as of different ages.

AGRICULTURAL ENGINEERING.

Report of the meteorologist and irrigation engineer, L. G. CARPENTER (*Colorado Sta. Rpt.* 1899, pp. 42-51, pls. 6).—The work of this department of the station during 1899, as in previous years (E. S. R., 11, p. 394), has been confined mainly to measurements of seepage, river flow, duty of water, and meteorological observations (see p. 220).

"The measurements to determine the gains or losses from seepage have been continued this year on streams previously measured. These include the Cache la Poudre, from the canyon to its mouth, a distance of 50 miles; the Big Thompson, about the same distance; the Little Thompson, a tributary of the Big Thompson;

the St. Vrain, from Lyons to the Platte, and its tributary, Left Hand Creek; the Rio Grande, from above Del Norte to the State line, a distance of about 100 miles; the Arkansas, from Canyon City to the Kansas State line, a distance of 200 miles; nearly 500 miles of river measurement in all for this particular purpose. . . . The general results of previous measurements are confirmed. A tendency to increase in the amount of water returning to the river is noticeable, especially on those streams where the return waters have some distance to pass to reach the stream. The Rio Grande is an exception in that a marked loss is noticeable at the rim of the valley. There is then a gain, but not enough to balance the loss."

A record in continuation of that of previous years is given of the weekly measurements (April 18 to November 28), by means of automatic instruments, of the flow during 1898 and 1899 of the Cache la Poudre River at a point about 12 miles from Fort Collins. The watershed above the point of measurement exceeds 1,000 square miles. The average of the weekly measurements was 431 cubic feet per second in 1898 and 860 in 1899, the normal for 15 years being 708 cubic feet per second. Of the quantity so measured an amount not exceeding 150 cubic feet per second is water diverted from other watersheds than that of the Cache la Poudre. Weekly bulletins of the flow have been prepared for the local use of papers in northern Colorado.

The results of several years' observations on the duty of water are being prepared for publication.

The effect of forests on the preservation of snow is illustrated by reproductions of photographs.

The use of water in irrigation in Wyoming. B. C. BUFFUM (*U. S. Dept. Agr., Office of Experiment Stations Bul. 81, pp. 56, pls. 8*).—This bulletin describes studies by the author during the past 9 years on the use of water in irrigation in Wyoming, and gives his conclusions regarding certain measures and methods needed to secure the largest service from the available supply. It discusses the application of water to crops, water measurements in Wyoming, duty of water, the irrigating season, and continuous flow as a basis for appropriation.

"In the region under discussion irrigation is chiefly from small streams, and nearly all of the water supply which can be diverted is appropriated, but large volumes of water still run to waste in the larger rivers. It is along these that we must look for future development, but the utilization of this supply involves questions outside the scope of this investigation. These large rivers as a rule drain the mountain summits and have a more uniform flow than the small streams, as the snows which feed them melt slowly. The small streams, on the contrary, fluctuate so widely in volume that it usually happens that more water runs to waste before irrigation of cultivated crops begins than is available for use in July, when the need for such crops is greatest. It is also an unfortunate circumstance that the most remunerative crops are those which require late irrigation. Sugar beets, potatoes, alfalfa, and orchards all require irrigation in August and September, which is the season of the least supply. These crops, while bringing large returns, require, as a rule, but little water, and their cultivation will secure a much higher average duty than now prevails; but to greatly extend the area of these products will involve comprehensive measures to increase through storage the present volume available for use in July, August, and September, because on three-fourths of the Wyoming streams there is now a scarcity in these

months. If this shall not prove feasible, then the future extension of the areas now irrigated will come chiefly through the cultivation of crops which can be brought to maturity by water supplied before June 15. Among these, forage crops take first rank, as they can be irrigated as soon as water can be turned in ditches, and the stimulus given by a single watering will secure at least a partial crop. All these crops, however, are wasteful of water, and if they are to predominate in the extension of the reclaimed area, as will be necessary without storage, we may expect to see the average duty remain fully as low as at present."

Silo construction and silage, C. M. CONNER (*South Carolina Sta. Bul.* 51, pp. 15, figs. 6).—The value of the silo to the southern dairyman as a means of providing succulent food for dairy animals during long dry summers is briefly discussed, and detailed directions, with illustrations, are given for the construction of a round silo; with suggestions as to location, size, method of filling, and crops to be grown for silage. The methods and details of construction described are those followed by the author in building a silo at the South Carolina Station.

On drainage of marshes, H. STEINMETZ (*K. Landt. Akad. Handl. Tidsskr.*, 39 (1900), No. 3, pp. 191-203).

Report of trials of agricultural machinery, U. SVERDRUP ET AL (*Christiania*, 1900, pp. 36, illus.).—The report gives detailed results of trials of 40 different makes of plows, the trials being conducted by a committee of the Royal Society for Norway's Weal.

Agricultural machinery in Denmark in 1899, C. V. BIRK (*Tidsskr. Landökon*, 1900, No. 3, pp. 149-164).

Trials of common plows and wheel plows, P. ULLBERG (*Landtmannen*, 11 (1900), No. 13-14, pp. 197-202, 215-218).

Trial of the potato harvester "Cambrian", U. SVERDRUP ET AL (*Tidsskr. Norske Landbr.*, 7 (1900), No. 1, pp. 38-40).

The social, commercial, and economic phases of the road subject, W. H. MOORE (*U. S. Dept. Agr., Office of Public Road Inquiries Circ.* 34, pp. 8).—A paper by the president of the State and Interstate Good Roads and Public Improvement Association.

STATISTICS—MISCELLANEOUS.

Twelfth Annual Report of Arkansas Station, 1899 (*Arkansas Sta. Rpt.* 1899, pp. 8-134).—The report proper contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1899, and a brief report by the director. Bulletins 56-60 of the station on the following subjects are reprinted: Tomatoes, cabbage, and onions (E. S. R., 11, p. 242); the relative virulence for the domestic animals of human and bovine tubercle (E. S. R., 11, p. 689); an experiment in grazing a corn and cowpea field with steers (E. S. R., 11, p. 965); yield of Spanish peanuts planted at different distances (E. S. R., 11, p. 927); planting unshelled peanuts (E. S. R., 11, p. 923); relative effects of cotton meal, whole and crushed seed, on the yield of corn, cotton, and potatoes (E. S. R., 11, p. 926); relative effects on cotton and corn of certain leguminous crops turned under entire and their stubble only turned under (E. S. R., 11, p. 921); Allen Hybrid cotton (E. S. R., 11, p. 926); the comparative yield of corn from seed of the same variety grown in different latitudes (E. S. R., 12, p. 136); second report on Arkansas seedling apples (E. S. R., 12, p. 151).

Twelfth Annual Report of Colorado Station, 1899 (*Colorado Sta. Rpt.* 1899, pp. 113, pls. 8, dgm. 6).—This contains the organization list of the station, a financial

statement for the fiscal year ended June 30, 1899, a report of the director discussing at some length the organization and work of the station and substations, an inventory of station equipment, detailed outlines of station work for 1899, and reports of the heads of departments and superintendents of substations noted elsewhere.

Fifteenth Annual Report of Maine Station, 1899 (*Maine Sta. Rpt. 1899*, pp. 171).—This contains the organization list of the station, a brief report by the director, and reprints of Bulletins 48-57 of the station on the following subjects: Feeding stuff inspection (E. S. R., 10, p. 1089), care of orchards (E. S. R., 11, p. 153), fertilizer inspection (E. S. R., 11, p. 137), feeding stuff inspection (E. S. R., 11, p. 279), the spraying of plants (E. S. R., 11, p. 262), fertilizer inspection (E. S. R., 11, p. 829), nuts as food (E. S. R., 12, p. 78), cereal breakfast foods (E. S. R., 12, p. 69), apple insects of Maine (E. S. R., 12, p. 68), experiments with potatoes (E. S. R., 12, p. 140). A list of acknowledgments, meteorological observations, and a report of the treasurer for the fiscal year ended June 30, 1899, are also included.

Twelfth Annual Report of Massachusetts Hatch Station, 1899 (*Massachusetts Hatch Sta. Rpt. 1899*, pp. 125).—A brief summary is given of station work during the year, which includes also a list of officers of the station and a list of station publications now available for distribution. A financial statement is given for the fiscal year ended June 30, 1899. Reports of the agriculturist, botanists, meteorologist, horticulturist, entomologist, and chemists, parts of which are noted elsewhere, are included, which review in detail the different lines of station work during the year and give results in some cases.

Twelfth Annual Report of Mississippi Station, 1899 (*Mississippi Sta. Rpt. 1899*, pp. 47).—This contains the organization list of the station, reports of the director and treasurer for the fiscal year ended June 30, 1899, and departmental reports, parts of which, together with notes on forage crops and a meteorological summary, are noted elsewhere. Reprints of Bulletins 53 to 59 of the station, with the exception of Bulletins 55 and 57, on the following subjects are appended: Some insects injurious to stock and remedies therefor (E. S. R., 11, p. 272), Irish potato culture (E. S. R., 11, p. 241), grapes (E. S. R., 11, p. 253), soils of Mississippi—texture and water conditions (E. S. R., 11, p. 328), and analyses of commercial fertilizers (E. S. R., 11, p. 528).

Tenth Annual Report of North Dakota Station, 1899 (*North Dakota Sta. Rpt. 1899*, pp. 56).—This contains the organization list of the station, a brief general report on station work during the year, detailed reports on the work of the different departments, parts of which are noted elsewhere, and a financial statement for the fiscal year ended June 30, 1899.

Twelfth Annual Report of Vermont Station, 1899 (*Vermont Sta. Rpt. 1899*, pp. 119-354).—This includes the organization list of the station, financial report for the fiscal year ended June 30, 1899, report of the director reviewing at some length the work and publications of the station during the year, abstracts of Bulletins 60-71 of the station, and departmental reports abstracted elsewhere.

Record of six years' work at the Plains Substation, J. E. PAYNE (*Colorado Sta. Rpt. 1899*, pp. 71-95, pls. 5, fig. 1).—This station has previously been known as the "Rainbelt Substation." The record here given is a summary statement of the results secured at the station with a large number of farm, orchard, and garden crops for each of the years the station has been in existence. The results are largely negative.

Report of the Rainbelt Substation, J. E. PAYNE (*Colorado Sta. Rpt. 1899*, pp. 52-55).—The report includes notes on fruit set out at the station and now living, on the growth of certain field crops, and recommendations as to further work.

The agricultural experiment stations in the United States, A. C. TRUE and V. A. CLARK (*U. S. Dept. Agr., Office of Experiment Stations Bul. 80*, pp. 6-36, pls. 153).—This is an exhaustive report on the history and present status of the agricultural

experiment stations in the United States prepared as a part of the experiment station exhibit at the Paris Exposition. It includes a statement concerning the general agricultural conditions in the United States as related to the work of the stations; an historical review of the organization and development of the stations, together with an account of the early experimental work carried on by the agricultural colleges and other institutions prior to the establishment of the stations under the Hatch Act; a statement of the relations of the stations to the Federal Government and to several associations, accounts of which are given; a discussion of the organization, equipment, lines of work, and general results of the work of the stations; an extended account, comprising the larger part of the volume, of the Office of Experiment Stations and of the individual stations, giving in each case the history, organization, equipment, financial support, lines of work, publications, and general results of work; and an appendix containing an account of the inspection work of the stations with the principal features of the laws under which it is carried on, the general statistics of the stations, a list of the publications issued by them since their organization, a descriptive account of the card index of experiment station literature, a list of books published by experiment station workers, and a catalogue of the experiment station exhibit at the Paris Exposition.

Statistics of the land-grant colleges and agricultural experiment stations in the United States for the year ended June 30, 1899 (*U. S. Dept. Agr., Office of Experiment Stations Bul. 78, pp. 39*).—A summary of this has already appeared (*E. S. R.*, 11, p. 801).

Farmers' institutes: History and status in the United States and Canada, L. H. BAILEY (*U. S. Dept. Agr., Office of Experiment Stations Bul. 79, pp. 34*).—This bulletin gives a general survey of farmers' institutes and historical and statistical information regarding the movement in the different States and Provinces. A list of officials in charge of farmers' institutes in the United States is appended.

Experiment Station Work—XIV (*U. S. Dept. Agr., Farmers' Bul. 114, pp. 28, figs. 5*).—This number contains articles on the following subjects: Influence of salt and similar substances on soil moisture, extra-early potatoes, rotting of cranberries, chestnuts, low-grade Paris green, crude petroleum as an insecticide, skim milk in bread making, best number of hens in one pen, nest box for egg records, and profitable and unprofitable cows.

Crop circular for April, 1900, J. HYDE (*U. S. Dept. Agr., Division of Statistics Crop Circ. Apr., pp. 4*).—This contains notes and tabulated data on the condition of winter wheat and rye and of farm animals throughout the United States on April 1, 1900, and estimated losses of horses, cattle, sheep, and swine from exposure and disease during the year ended March 31, 1900.

Agricultural imports and exports, 1895-1899 (*U. S. Dept. Agr., Section of Foreign Markets Circ. 22, pp. 15*).—Tables are given showing the nature, quantity, and value of the agricultural imports and exports of the United States during each of the 5 fiscal years, 1895-1899.

Warehouses: A study of the organization of the grain trade in America, India, and Russia as well as in some German States, O. BÖHM (*Die Kornhüner; eine Studie über die Organisation des Getreide Verkaufes in Amerika, Indien, und Russland, sowie in einigen deutschen Staaten. Stuttgart: J. G. Cotta, 1898, pp. 96*).

NOTES.

ALABAMA COLLEGE AND STATION.—B. B. Ross, professor of chemistry in the college and State and station chemist, has been granted a year's leave of absence, which he will spend in study in Europe. During his absence J. T. Anderson, associate chemist of the station, will be acting State and station chemist, and Paul Murrill, recently of the University of Michigan, will be acting professor of chemistry in the college. C. F. Austin, a graduate of the Michigan Agricultural College, and formerly connected with the Montana Station, has been appointed assistant horticulturist of the station. A residence is being erected for the assistant agriculturist.

ARIZONA STATION.—David Griffiths, Ph. D., has been appointed botanist of the station. He is to make a specialty of range study and improvement, in which work the Arizona Station is cooperating with the Division of Agrostology of this Department. Three hundred and twenty acres of worn-out range near Tucson is now under fence and is to serve as a main reserve for this study.

CALIFORNIA STATION.—C. A. Colemore has been appointed clerk to the director, *vice* A. V. Stubenrauch, resigned. The post-office address of the Southern California Substation has been changed from Pomona to Ontario, and the station now has the advantage of the rural delivery system. Some important changes are under way at the substation near Paso Robles. For the past ten years a large number of deciduous fruit trees have been tested upon land underlaid at a few feet by a very thick bed of siliceous hardpan. This orchard is being removed, and the result of the tests will shortly appear in a bulletin. Several *Phagodia* and two new *Atriplexes* from South America have been successfully grown at the substation and their culture is to be tested on a larger scale. Five successive dry seasons in the Paso Robles region have emphasized the need of drought-resisting forage plants, and 9 species of perennial grasses, out of some 60 tested in recent years, are considered worthy of more extensive planting. A dairy herd of 17 cows has been placed at the service of the central station, and feeding experiments will be conducted with sugar-beet pulp, and later comparative experiments will be made with cocoanut and other oil-cake meals.

COLORADO COLLEGE AND STATION.—F. L. Watrous, who has been assistant in agriculture for a number of years, has resigned, to take effect January 1, 1901. Clarence J. Griffith, former instructor in dairying at the Iowa Agricultural College, has been appointed to the same position in this college.

GEORGIA STATION.—The efforts of this station to encourage the general adoption of the plan of harvesting the corn crop by cutting down the entire stalk and shocking, and afterwards shredding the dried stover, are meeting with very gratifying success. It is probable that in the course of a few years farmers in the South will generally adopt the plan so long pursued in the North and West, thereby adding several million tons of good forage to the food resources of this section.

IOWA COLLEGE AND STATION.—John Craig has resigned his position as horticulturist to take charge of university extension work in New York. John A. Craig has been made assistant director in addition to his duties as professor of animal husbandry.

KANSAS COLLEGE AND STATION.—E. R. Nichols, who was acting president of the college for the year ended June 30, 1900, has been elected president. The year just concluded has been one of the most successful in the history of the institution. The

total attendance was 1,094, which was far in excess of any previous year. Paul Fischer, veterinarian in the college and station, has resigned to accept the newly established professorship of bacteriology and animal pathology in Ohio University.

KENTUCKY STATION.—J. B. Marcum, of Jackson, Ky., has been made a member of the governing board; J. W. Nutter has been appointed dairyman, and J. D. Turner and R. M. Allen clerks at the station.

U. S. DEPARTMENT OF AGRICULTURE.—William Saunders, for the past thirty-eight years Superintendent of Experimental Gardens and Grounds, died September 11, 1900, at the age of 78 years. He has been succeeded by B. T. Galloway, who in turn has been succeeded by Albert F. Woods as Chief of the Division of Vegetable Physiology and Pathology. The Secretary of Agriculture has published the following general order: "For the purpose of unifying the work of certain branches of the Department it is hereby ordered that the Chief of the Division of Vegetable Physiology and Pathology, the Chief of the Division of Agrostology, and the Chief of the Division of Pomology confer upon all matters of general policy and plan with the Superintendent of Experimental Gardens and Grounds, who is hereby designated as Director of Plant Industry. In carrying out this order the several branches of the Department named will maintain their present integrity and organization." A laboratory for the physical and chemical study of road materials has been established in the Division of Chemistry. "The object of the establishment of this laboratory is to secure the widest possible knowledge of the nature of road materials, their resistance to stress, their hardness, their power of absorbing water, their deportment in freezing temperatures, their cementing properties when reduced to powder, either alone or when mixed with other substances, their chemical composition, and their geological origin and distribution."

MISCELLANEOUS.—According to *The Country Gentleman* the Doylestown (Pa.) Farm School has been proffered a 150-acre farm in Bucks County, valued at \$50,000, on condition that an endowment is provided for its maintenance. This is to be run as an annex to the school at Doylestown, for training girls in farmhouse work. The school has also received a contribution of \$10,000 from a friend in Switzerland, to be used for buying farms "on which graduates may test their abilities."

From the same source it is learned that Union Academy at Belleville, N. Y., has received a gift of \$10,000 to establish a department of agricultural instruction.

By a decree of the Minister of Agriculture of France there has been established a Station of Oenology at Toulouse. The director will be J. Vincens.

PERSONAL MENTION.—Dr. Oscar Loew, who for two years past has been connected with the Division of Vegetable Physiology and Pathology of this Department, has been elected professor of agricultural chemistry in the University of Tokyo, Japan, and will enter upon his duties there at once.

Dr. J. Behrens has been chosen director, and has entered upon the duties at the recently established Viticultural Experiment Station at Weinsberg, in Würtemberg.

Dr. O. Mattiolo, professor of botany in the Institute of Florence, has become professor ordinary in botany at the University of Turin.

Dr. F. Cavara, late of the Forest Academy at Vallambrosa, has been chosen professor extraordinary in botany in the University of Cagliari.

Dr. A. Maurizio, of the Experiment Station for Milling in Berlin, has become assistant in botany in the Federal Agricultural Experiment Station at Zürich.

Dr. A. Richter has been chosen director of the Botanical Institute and Gardens at Klausenburg.

EXPERIMENT STATION RECORD.

EXPERIMENT STATION RECORD.

VOL. XII

No. 4.

The exhibits of the agricultural experiment stations of the world at the Paris Exposition considered collectively constituted the most extensive and instructive representation of experiment station work and equipment that has ever been collected. They included contributions from most of the leading countries in which experiment stations are maintained, conspicuous exceptions being Belgium, Canada, Holland, Italy, Sweden, and Switzerland. The impression which might have been made of the magnitude which the experiment station enterprise has assumed during the last decade and of the great diversity of the interests and activities of the stations was largely obscured under the system by which the exhibits were classified. Under this system, or at least under its interpretation, the station exhibits were widely separated, a part placed under "agricultural experiment stations and statistics," a large number under "education," and others in the general agricultural exhibits of their respective countries, while still others were to be found in some of the national buildings. This made it extremely difficult to locate the station exhibits of different countries and well-nigh impossible to find all of the exhibits without reading the entire catalogue of the exposition. This probably accounts for the disparity of the reports brought back by different visitors to the exposition.

For the most part the exhibits were individual rather than collective. The German exhibit was designated a collective one, but was so only in the sense of being brought together in the same space. The exhibit of each station, however, was kept separate from the other, and various commercial displays of apparatus, etc., were installed between the exhibits of individual stations. The stations in the United States had the only strictly collective exhibit, although in the case of several countries the entire exhibit was made by a central station or a ministry of agriculture. There was good opportunity to compare the relative merits of the collective and the individual plans of making exhibits.

The French exhibit as a whole was large, although it did not so impress the observer on account of the individual and scattered plan of installation. Most of the stations were represented in the educational section in connection with the agricultural schools or institutes with which they are affiliated. In addition to photographs of fields,

plats, and stock, plans of buildings, charts, etc., some of the stations showed models of beets grown with different fertilizers, and the sugar and alcohol obtained from them; samples of grains from different sections, and of the soil and rocks of the respective sections; microphotographs of yeasts and bacteria; apparatus for testing agricultural machines, and specimens of plants and seeds grown under various conditions of experiment. A number of pieces of original apparatus were shown, among them Bartmann's apparatus for stirring solutions in six beakers simultaneously, and a filter siphon. The station for agricultural climatology at Juvisy presented a temperature and rainfall record covering two hundred years, beautiful photographs illustrating the classification of clouds, a section of the soil of the plateau of Juvisy, showing 16 strata, and the work of Flammarion on the effect of different colored rays of light on the development of plants. The station for sericulture at Manosque illustrated the culture of silkworms and the work which it is doing in silk production. The investigations of L. Grandeau on the feeding of cab and omnibus horses was illustrated by sample rations, dynamometers, and other apparatus used, and charts. These formed a novel and interesting feature.

The exhibit of the German stations, which was one of the largest in its class, was shown in connection with the general agricultural exhibit of Germany. The handbook of the latter gave a review of the development and present status of the experiment stations in Germany by Professor Nobbe, and a short account of the history, organization, and lines of work of each station, with an enumeration of the material exhibited. This furnished quite complete and systematic data for the German stations, some of the statistics being especially interesting. The total revenue of the 73 stations enumerated is given as 2,244,630 marks, or approximately \$94,312, 26.8 per cent of which comes from the general government, 2.6 per cent from the provincial government, 40.7 per cent from agricultural and other societies, and nearly 30 per cent from fees for analysis and control work.

The Moor station at Bremen exhibited several pieces of special apparatus for the investigation of moor soils, such as the determination of substances injurious to plants, absorptive properties, and the free humic acids, and a large collection of photographs showing experiments to test fertilizers and various kinds of physical treatment, the deleterious effects of perchlorate on rye, etc. The photographs illustrating the reclamation of moors were interesting and instructive.

The Darmstadt station showed only photographs illustrating its various pot and field experiments. The Halle station showed apparatus for determining phosphoric acid and nitrogen on a commercial scale, and an interesting set of photographs illustrating the results of vegetation experiments on the question of nitrification in the soil and the treatment of barnyard manure. The station for plant protection

at Halle made an interesting exhibit of apparatus employed in its work, herbaria, specimens, etc.; and the seed-testing station at Hamburg displayed enlarged photographs and samples of weed seeds of different origin which have been found in grass and clover seed. Samples of clover seed from different countries with the several impurities separated were displayed in watch glasses. The experiment station at Kiel showed special apparatus, much of it original, used in the examination of feeding stuffs for composition and purity; and the station at Marburg exhibited Dietrich's apparatus for determining the weathering of soil-producing rocks, and a rather complicated vegetation apparatus for studying the effect of specific bacteria on plant growth. The Möckern station illustrated the Pettenkofer respiration apparatus by means of charts, photographs, and models of parts, and showed the results of experiments on the metabolism of nitrogen, carbon, and energy with oxen. In the same line was an exhibit from the Bonn station of apparatus for collecting the urine and feces in metabolism experiments with cows, and two methods of determining dry matter in feeding stuffs in connection with such experiments. Several pieces of apparatus for soil investigation were shown by the Rostock station, and the agricultural high school at Berlin showed, by means of charts, 60 typical profiles of German soils, together with analyses of the same, and 12 polished marble plates illustrating the solvent action of the roots of a considerable number of common crops. The Tharand station made quite an elaborate display of apparatus for testing seed as to purity and determining their volume, and of the results of vegetation experiments on the action on Leguminosæ of pure cultures of tubercle bacteria, showing by means of photographs the effect of different kinds of nitragin. The exhibits of experimental work in dairying were made by the stations at Kiel and Kleinhof-Tapiau and the dairy institute at Hameln. These included different kinds of apparatus for the examination of milk, separation of constituents, etc., among which were a Renke-Stutzer apparatus for determining the amount of dirt in milk, cultures by Weigmann of bacteria for ripening cream (in liquid and dried form), and a collection of photographs of bacteria isolated from milk, butter, and cheese. There were various charts showing the effect of period of lactation and feeding on the composition of butter fat, and the results of systematic examination of the milk of 63 cows during one or more periods of lactation at Kleinhof-Tapiau.

The various pieces of apparatus displayed in the German exhibit were described as to principle and method of use in the handbook mentioned above. This added much to the interest and to an intelligent understanding of the apparatus, and made possible a more thorough study of the progress in methods of investigation.

The Rothamsted station had a small exhibit which consisted for the

most part of charts and illustrations, samples of wheat grown on soil which had been cultivated continuously in wheat for fifty-six years, together with samples of the soil.

The Japanese stations were represented by thirty-two charts giving the results of experiments with rice, photographs illustrating different operations in rice growing, and a map showing the location of the stations. These stations also made a good exhibit of native food products.

The most prominent feature of the exhibit of the Danish stations was a model of the buildings and grounds of the Royal Veterinary and Agricultural Institute at Copenhagen, which was about 9 feet square. Most of the exhibit came from that institution. It consisted of photomicrographs of milk bacteria and fat globules; a Fjord milk tester; model of an improved ice house; samples of Danish cereals, brewing barley, and soils; a graphic representation of the results of feeding experiments, and a map showing the location of the stations and experimental fields.

The exhibit of the Russian stations formed a part of that of the ministry of agriculture and was in conjunction with that of the agricultural societies. A sample of the chernozem or black soil of Russia, about 18 inches square and 1 meter thick, showed the depth to which the humus or black soil extends, the yellow subsoil just showing at the bottom of the sample. A number of agricultural societies showed samples of grains, vegetables, flours, dairy products, wool, etc., and the laboratory of agricultural bacteriology at St. Petersburg had an interesting exhibit of photographs of cultures and culture tubes showing the application of biology in wine making, dairying, the destruction of rodents, and in soil studies. The station for silkworm culture at Tiflis also made a very interesting exhibit consisting of photographs of the buildings, laboratories, and workrooms, and samples of young mulberry trees and models of trees illustrating the method of pruning. The life history of the different kinds of silkworms was shown, together with samples of the silk and of silk fabrics made at the station. In addition to this the station displayed photographs and models of beehives used for experimental purposes.

The seed-control station at Vienna illustrated its work by models of machinery for cleaning seed, the ordinary apparatus used in seed testing, photographs of laboratories and experimental fields, and a file of its publications and those of the branch stations connected with it.

The exhibit of the Hungarian stations was very creditable, and was especially interesting on account of the general lack of definite knowledge regarding the activity of these stations. The stations interested in viticultural work made a fine display of apparatus, models of buildings and of plants, showing the methods of cultivating and pruning the grape, and photomicrographs showing the anatomical structure of

the vine, the union of grafts on the vine, and ferments found in wine. Spraying apparatus, all of the knapsack type, soils from typical viticultural regions with separations made by the elutriator, and maps, charts, and pictures were also shown.

The ministry of agriculture of Bosnia made a good showing for the stations in that small country. The exhibit consisted of plans and photographs of the stations and their work, specimens showing methods of pruning the vine, varieties of grapes, and other viticultural work.

Mention has been previously made of the general character of the experiment station exhibit of the United States (E. S. R., 11, p. 601). Although it occupied rather an unfortunate location, it was sought out by a considerable number of persons especially interested in agricultural experimentation, and was highly complimented by members of the jury of awards.

As a rule, the station exhibits were quite representative of these institutions, collectively and individually, and brought them into prominent notice as established agencies for the advancement of agricultural science. On account of the extent of the representation and the diversity of the exhibits, there were many features of general interest to experiment station workers and of especial interest to those who have taken an active part in planning and preparing such exhibits in the past. To those who were able to study the methods of display which were followed by different countries, the exhibits furnished some valuable lessons and suggestions which should be helpful in the future.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The direct determination of available phosphoric acid, F. P. VEITCH (*Jour. Amer. Chem. Soc.*, 21 (1899), No. 12, pp. 1090-1094).—The author investigated the cause of the discrepancy between results obtained by the Ross direct method,¹ and the official method, and found it to be due to the fact that no account was taken in the Ross method of the phosphoric acid removed in the water used in washing the citrate-insoluble residue. Tests were made of the citrate and molybdate methods for the direct determination of available phosphoric acid with results very favorable to the latter method, which was carried out as follows: "The water-soluble, extracted as usual, was received in a 500 cc. flask, graduated roughly at 250 cc. and containing 5 to 10 cc. nitric acid. The citrate-soluble was then extracted as usual, the filtrate and washings received in the flasks with the water-soluble. After cooling, the volume was completed, shaken, filtered, and in aliquots of 100 cc. the phosphoric acid was determined . . . the molybdate solution being added directly to the solution without destroying the organic matter, but the precipitates were allowed to stand over night before filtering. The determinations were completed as usual."

Note upon the determination of nitrogen in fertilizers containing nitrates, F. P. VEITCH (*Jour. Amer. Chem. Soc.*, 21 (1899), No. 12, pp. 1094, 1095).—The following modification of the Fields-Gunning method² has been used by the author with very satisfactory results: "To the nitrate in the digesting flask are added 35 to 40 cc. sulphuric acid containing 34 gm. salicylic acid per liter. Allow to stand in the cold until the nitrate is dissolved. Add 6 or 7 gm. of finely broken potassium sulphid, heat over a low flame for 15 minutes, then over the full flame until clear. Cool and distil as usual."

The gasometric measurement of nitrites in the presence of nitrates or other soluble salts, J. GAILLIAT (*Jour. Pharm. et Chim.*, 6. ser., 12 (1900), No. 1, pp. 9-12; *abs. in Chem. News*, 82 (1900), No. 2126, pp. 87, 88).—The method proposed is based upon the fact that when a solution of neutral metallic nitrite is added to an excess of neu-

¹ U. S. Dept. Agr., Division of Chemistry Bul. 38, p. 17.

² *Jour. Amer. Chem. Soc.*, 18 (1896), p. 1102 (*E. S. R.*, 8, p. 663).

tral, boiling, concentrated solution of ammonium chlorid a regular disengagement of nitrogen takes place according to the following formula: $\text{NH}_4\text{Cl} + \text{NO}_2\text{M} = \text{N}_2 + 2\text{H}_2\text{O} + \text{M}^+\text{Cl}$. The nitrite is estimated either from the amount of nitrogen given off or of ammonium chlorid decomposed. The author considers the former method preferable. He uses for the collection and measurement of the nitrogen a modification of Schloesing's apparatus for the determination of nitrates.

The distillation of ammonia in the determination of nitrogen, F. G. BENEDICT (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 5, pp. 259-263, fig. 1).—The essential feature of the method proposed consists in distilling the liquid through a condenser surrounded by cold water, which is allowed to run out a few minutes before the end of the distillation, so that the condenser tubes may become heated and the ammonia driven out of them by a current of live steam. In this way about 20 minutes' distillation suffices to drive over all of the ammonia. A form of distillation apparatus adapted to this method is described.

Lime and sulphuric acid by the photometric method, J. I. D. HINDS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 5, pp. 269-274).—In this method (E. S. R., 8, pp. 201, 202) lime is precipitated in the solution to be tested with solid calcium oxalate and sulphuric acid with solid barium chlorid. A cylinder 3.5 cm. wide and 20 cm. high, graduated in centimeters and millimeters, is held over a sperm or wax candle and the water containing the precipitate is poured into it until the image of the flame just disappears. The depth in the cylinder is read and the percentage is calculated from equations or read from tables which are given in the article.

The estimation of fat in sweetened condensed milk by the Babcock test, E. H. FARRINGTON (*Amer. Chem. Jour.*, 22 (1900), No. 3, pp. 267-270).—In testing sweetened condensed milk by the Babcock test the excess of cane sugar causes a poor separation of the fat, preventing a satisfactory reading. The author finds that the sugar can be washed out without removing any of the fat. In making the test, preferably 60 gm. of condensed milk is dissolved in 100 cc. of water, the volume made to 200 cc., and 17.6 cc. of this solution mixed in a Babcock test bottle with about 3 cc. of the sulphuric acid commonly used for testing milk. The bottle is whirled for about 6 minutes in a turbine centrifuge heated to about 200° F., in order to compact the curd into a firm lump. The whey containing the sugar is poured off, 10 cc. of water added to the curd and 3 cc. of acid, and the whirling repeated. After pouring off the whey a second time the curd is mixed with 10 cc. of water and 17.5 cc. of sulphuric acid, and the test then made as usual. "Careful tests of the whey poured off from the test bottles showed that no fat was lost by this decantation if the whey was clear and contained no pieces of curd." The results of tests of a number of samples by this method are reported.

A new method of ash determination, A. E. SHUTTLEWORTH (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 42-44, figs. 4).—This relates to the use of acetate of lime to prevent the formation of indecomposable silicates, and the author's platinum apparatus (E. S. R., 11, p. 304).

Contribution to the knowledge of metaphosphate, G. VON KNORRE (*Ztschr. Anorgan. Chem.*, 24 (1900), p. 369; *abs. in Chem. Ztg.*, 24 (1900), No. 66, *Repert.*, p. 233).—The author concludes from his investigations that all of the five known modifications of metaphosphate may be represented by the formulas $(R^1PO_3)_n$ and $(R^{11}P_2O_6)_n$, all combinations containing 1 molecule each of base and phosphoric anhydrid.

A process for preventing the reversion of soluble phosphoric acid in superphosphates dried by heat by means of compressed air or a current of air (*L'Engrais*, 15 (1900), No. 30, p. 712).—A brief note is given on a process patented by J. Lùjens.

Determination of nitrous acid, G. ROMIJN (*Chem. Ztg.*, 24 (1900), No. 15, pp. 145, 146).

Critical studies on the more important reagents for the detection of nitric acid in water, H. MENNICKE (*Ztschr. Angew. Chem.*, 1900, No. 29, pp. 711-719; *abs. in Chem. Centbl.*, 1900, II, No. 7, p. 444).—After testing numerous methods the author gives preference to Erdmann's method (E. S. R., 12, p. 18).

On the determination of perchlorate in nitrate of soda, C. AHRENS and P. HETT (*Ztschr. Angew. Chem.*, 1900, No. 17, p. 419).—A denial of Woy's statement¹ that platinum dishes are injured by use in the determination of perchlorates by the author's method (E. S. R., 11, p. 110).

The determination of iodic acid in nitrate of soda, M. R. AUZENAT (*Rev. Chim. Analyt. et Appl.*, 5 (1900), No. 3, pp. 84, 85).—The limited application of Beckurts' and Rammelsberg's methods is noted. By a slight modification of the latter method the disturbing influence of potassium perchlorate is avoided. The method consists of comparing the color produced by the liberation of the iodine with that produced by a solution containing a known amount of potassium iodid. Complete directions are given as to manipulation.—H. SNYDER.

BOTANY.

The migration of food material in leaves, G. M. TUCKER and B. TOLLENS (*Ber. Deut. Chem. Gesell.*, 32 (1899), pp. 2575-2583; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 2, p. 220).—In the case of leaves of the plane tree, the weight of the ash is said to increase until the death of the leaves, and then slightly decline. The same is the case with silica and lime content, but chlorin and sulphuric acid show a continuous increase. Leaves gathered in November contain 3 times as much sulphuric acid as leaves gathered in June. Phosphoric acid and potash increase slightly until the death of the leaves, after which they diminish to less than one-half their original quantity. The amount of nitrogen decreases continually to less than one-fourth its original quantity. There appears to be but little retrogression of food materials from the leaves to the stem or branches. Rain, it is said, has little if any washing-out action on the food material in the leaves.

A contribution to the knowledge of arginin, U. SUZUKI (*Bul. Col. Agr. Tokyo*, 4 (1900), No. 1, pp. 68, *dgms.* 6).—The author has made a study of the seeds and shoots of a number of Japanese plants in order to investigate the question of the presence, formation, and transformation of arginin and its relation to the regeneration of proteids and the influence of light and other agents upon these processes. The seeds and shoots of *Cryptomeria japonica*, *Gingko biloba*, and *Pinus thunbergii* were investigated and arginin isolated from them. It was found that the proteids prepared from the seeds of these plants produced, under the action of dilute acids, a considerable quantity of organic bases, the chief of which was arginin. This is particularly abundant in the etiolated shoots of *Cryptomeria* and *Pinus* and exists in a small quantity in the shoots of *Gingko*. The chemical nature of the proteids examined in both the shoots and seeds is considered identical as they gave the same decomposition products.

In the second portion of the paper the author reports investigations of the synthetical formation of arginin; the effect of light and mineral nutriment upon its formation and transformation, studying not only coniferous plants but a number of others. It was found that arginin in coniferous plants is not only the result of a decomposition of proteids but can be synthetically formed from ammonium salts and also probably from nitrates. Those plants not belonging to the Coniferae which were examined were unable to produce arginin by the assimilation of ammonium salts, asparagin being their only product. The synthetical formation of arginin took place equally well in diffused and bright sunlight. Whether it is formed in darkness is as yet undetermined. It was found to accumulate in large quantities in the shoots of Coniferae in the dark as well as in daylight during the first stages of germination but the amount diminishes on further exposure to light. Its transformation into proteids may be accelerated under the influence of light by the addition of mineral nutrients. While the greater part of arginin is believed to come from reserve proteids by hydrolytic decomposition, a considerable portion is thought to come from the transformation of other amido compounds. Consequently it is not only a primary but a secondary product.

Synthesis of albuminoids, W. PALLADIN (*Charkow*, 1898; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 2, p. 223).—In addition to the intermediate products of the primary synthesis of albuminoids, it is said that there are products of the decomposition of albuminoids, intermediate products of the regeneration of the decomposition products, and various special products of the breaking up of the albuminoids. The decomposition of albuminoids takes place only in growing organs. In *Urtica lactuca* and *Euteromorphia intestinalis*, asparagin was found, but no tyrosin. From this it is stated that the first stage in the primary synthesis of albumen can not be tyrosin. Asparagin and

tyrosin are both considered simple products of the decomposition of albuminoids. In *Salicornia herbacea* neither asparagin nor tyrosin was found. In the leaves of *Robinia pseudacacia* there was present small amounts of asparagin but no tyrosin, while in the leaves of *Dahlia variabilis* in August neither asparagin nor tyrosin was present.

A contribution to the study of nitrogen assimilation by legumes, LUTOSLAWSKI (*Centbl. Agr.*, 1899, Oct., p. 688; *abs. in Ann. Agron.*, 26 (1900), No. 8, pp. 415, 416).—An attempt was made to study the fixation of nitrogen by leguminous plants at different stages of their growth. The plants selected for the experiment were peas, and were grown in pots which contained 6 kg. of soil from a field where peas had been grown the previous year. Mineral fertilizer composed of kainit, superphosphate and nitrate of soda, 1.277 gm. per pot, was added to the soil. The different phases of growth recognized were (1) from the beginning of germination until the period just preceding flowering, at which time the plants bore from 8 to 10 leaves; (2) at the beginning of flowering; (3) at full flower; (4) at the falling of the flowers; and (5) at maturity. The total increase for the peas grown in pots receiving no nitrogenous fertilizer for the different periods was 1, 1.65, 3.14, 5.17, and 3.40 per cent. The corresponding numbers for the peas which had received nitrogenous fertilizers were 0.145, 1.89, 2.95, and 2.20 per cent, the ability to assimilate nitrogen in the case of the plants receiving fertilizers not having manifested itself in the first period.

Further observations on the nature and functions of the nodules of leguminous plants, MARIA DAWSON (*Phil. Trans. Roy. Soc. [London]*, 1900, pp. 51-67, pls. 2; *abs. in Proc. Roy. Soc. [London]*, 66 (1900), No. 425, pp. 63-65).—In continuation of a previous paper (*E. S. R.*, 11, p. 25), the author reports on the morphology and nature of the organisms occurring in the root tubercles of a number of species of leguminous plants.

A further study of the morphology leads to the conclusion that no definite line of distinction can be drawn between genera in which filaments occur in tubercles and those in which they have not yet been observed. Some peculiar anatomical characters were noted in some of the tubercles, which are to be studied further. In the study of the organisms of *Desmodium gyrans* it was ascertained that the formation of X and Y forms arises by distinct lateral branching of the straight rods. After 12 to 14 days' culture, the individual long rods tend to break up into small ones, and the branched forms become disjointed in a similar manner.

A general study of these organisms and parallel cultures of Nitragin compared with pure cultures from *Pisum* tubercles shows that they all grow readily on gelatin or agar media containing an extract of pea stems, asparagin, and sugar, but very slowly on broth gelatin. They

do not peptonize milk, but upon potatoes a watery streak is formed in about 5 days. In liquid media, such as pea extract, a thick zooglæa-like film forms in from 12 to 14 days. The presence or absence of spores in these films is now under investigation. The organisms are aërobie, and may pass through a short motile stage, but the presence of cilia has not yet been demonstrated. Investigations are now in progress to determine whether these organisms are in themselves capable of fixing free nitrogen or of converting nitrogen in the form of ammonium salts into nitrites or nitrates.

Experiments made to determine the action of the organisms found in one genus of plants on specimens of another tribe or genus suggest that there is probably but one organism capable of producing tubercles on leguminous plants, but that in each particular host special physiological conditions exist to which the organisms become so especially adapted as to make it difficult for successful reciprocal action to take place between plants not nearly allied.

Experimental cultures in sterilized and unsterilized media indicate best results when nitrates without organisms are supplied to the plants in sterilized soil. In unsterilized media a small increase in crop may result from the use of Nitragin.

An experiment with inoculating soy beans, C. B. LANE (*New Jersey Stat. Rpt.* 1899, pp. 199, 200).—An experiment with soy beans was begun in 1896, in which 1 acre of wheat was followed two succeeding seasons with soy beans. The roots of the plants were examined from time to time but no tubercles found. The third season an attempt was made to introduce the germs of the soy-bean tubercle by adding soil from old soy-bean land and by adding dust from the floor where soy beans had been threshed. Examinations were made of the plants and abundant tubercles were found on both the inoculated plats, and a few scattering ones, or frequently none at all, on the untreated ones.

The results of this experiment show the practicability of transferring the tubercle organism through means of soil or dust.

An annotated catalogue of the ferns and flowering plants of Oklahoma, E. E. BOGUE (*Oklahoma Sta. Bul.* 45, pp. 48).—This bulletin gives a list of 750 species of plants, together with brief notes on their distribution and economic importance.

Native Oklahoma plants, E. E. BOGUE (*Oklahoma Sta. Bul.* 45, popular ed., pp. 12).—A popular edition of Bulletin 45 of this station, giving notes on the distribution of the plants throughout the Territory.

Notes on plants of 1899, F. L. HARVEY (*Maine Sta. Bul.* 61, pp. 43, 44).—Brief notes are given on a dozen species of weeds and other plants sent to this station for identification.

Root systems of farm crops, A. M. SOULE (*Tennessee Sta. Rpt.* 1899, pp. 42-45, figs. 4).—Notes are given on the development and distribution of the roots of maize in the soil.

Investigations on cleistogamous flowers, LECLERC DU SABLON (*Rev. Gén. Bot.*, 12 (1900), No. 140, pp. 305-318, figs. 18).—Studies are given on the structure and

fertilization of the cleistogamous flowers of *Viola odorata*, *Oxalis acetosella*, *Linaria spuria*, and *Leersia oryzoides*.

A contribution to the life history of *Quercus*, A. H. CONRAD (*Bot. Gaz.*, 29 (1900), No. 6, pp. 408-418, pls. 2).

The life history of flax and clover dodder, G. WILSDORF (*Fühling's Landw. Ztg.*, 48 (1899), Nos. 14, pp. 544-550; 15, pp. 561-567).—Studies are reported on the germination; experiments on dodder seedlings, with reference to the host plant; the haustoria and methods of attack, and growth and reproduction of the dodder.

A study of the leaf of the sugar beet at different periods of growth, P. WENDELER (*Deut. Zuckerind.*, 25 (1900), No. 24, pp. 969-971).—Shows the content of oxalic acid, total nitrogen, and proteid nitrogen.

Plant growth in oil, L. LUTZ (*Bul. Soc. Bot. France*, 3. ser., 47 (1900), No. 2-3, pp. 76-82, fig. 1).—An account is given of the growth of a number of fungi in castor oil and in vaseline. *Aspergillus repens* made a remarkable growth in both media.

Transpiration of evergreen leaves, O. ROSENBERG (*Öfvers. K. Svenska Vetensk. Akad. Förhandl.*, 1900, No. 1, pp. 85-98).

The utilization of the reserve materials of seeds during germination, MAZÉ (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 7, pp. 424-427).—Briefly outlines investigations on starchy and oleaginous seeds. The reserve materials of both are transformed into sugar for translocation. Enzymes are said to vary little in quantity between the third and sixth day of germination, and a temperature of 53° C. is the optimum for their activity.

The carbohydrate reserve of white clover seed, H. HÉRISSEY (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 25, pp. 1719-1721).—The carbohydrate reserve material in the seeds of *Trifolium repens* is said to be a mannogalactan, the properties of which resemble those exhibited in the reserve material of fenugreek and alfalfa seed. It is hydrolyzed by seminase, being at least partially transformed into reducing sugars.

Physiological observations on some perennial herbs, A. RIMBACH (*Bot. Gaz.*, 30 (1900), No. 3, pp. 171-188, pl. 1).—Notes are given on the underground structures and their development of a considerable number of perennial herbs.

On the absorption of soluble salts by plants, E. DEMOUSSY (*Thesis, Paris, 1899; noted from Ann. Agron.*, 25 (1899), Nos. 11, pp. 497-548; 12, pp. 561-607).—See E. S. R., 11, p. 1009.

On the presence of formaldehyde in plants, G. POLLACCI (*Rend. R. Inst. Lombardo Sci. e Lett.*, 2. ser., 32 (1899), pp. 4; *abs. in Bot. Centbl.*, 82 (1900), No. 4, p. 116).—Tests of green leaves of a number of species of plants are reported in which formaldehyde was found in the chlorophyll-bearing tissues when they had been exposed to the light.

Physiological investigations of inulase and inulin, A. RICHAUD (*Thesis, Paris, 1900, pp. 85*).

Photosynthesis in light which has traversed leaves, E. GRIFFON (*Rev. Gén. Bot.*, 12 (1900), Nos. 138, pp. 209-223; 139, pp. 272-288).—This paper gives the details of investigations on the effect of light made to pass through leaves on photosynthesis, a preliminary account of which has already been given (E. S. R., 11, p. 1010).

A chemical study of chlorophyll assimilation, S. POSTERNAK (*Rev. Gén. Bot.*, 12 (1900), Nos. 133, pp. 5-24; 134, pp. 64-73).—Discusses the first product produced from phosphoric acid in green plants and the physiological rôle of inosite.

Phyllorubin, a new derivative of chlorophyll, L. MARCHLEWSKI (*Inc. Akad. Wiss. Krakau*, 1900, No. 2, pp. 63, 64).

The importance of mycorrhiza, a comparative biological study, E. STAHL (*Jahrb. Wiss. Bot.*, 34 (1900), No. 4, pp. 539-688, figs. 2).

Origin of the Basidiomycetes, G. MASSEE (*Jour. Linn. Soc. Bot. [London]*, 34 (1900), No. 240, pp. 438-448, pls. 2).—Notes on the morphology and affinities of this group of fungi.

The nodule organism of the Leguminosæ, R. G. SMITH (*Proc. Linn. Soc. New South Wales*, 24 (1900), No. 96, pp. 653-674, pls. 2).—A history of the organism and the results of the researches of the writer.

METEOROLOGY.

Frost fighting, A. G. McADIE (*U. S. Dept. Agr., Weather Bureau Bul.* 29, pp. 15, pls. 6).—This is a discussion of the methods of forecasting and protecting against frost, especially as practiced among the fruit growers of California. "The experience of the past 3 years warrants the statement that the loss due to frosts in California, hitherto considered unavoidable, can be prevented, and that unless extreme conditions, by which is meant lower temperatures by 5° than have ever yet been experienced in this State, occur, the citrus fruits of California can be successfully carried through the period when frost is likely." It is claimed that "the formation of frost is primarily a matter of air drainage," and fruit growers are urged to study the topography of their lands with a view to locating the areas over which the air is stagnant and consequently more subject to frost.

Attention is called to the following important relation, first pointed out by Prof. W. H. Hammon, which is useful in forecasting frosts for southern California: "A wave of falling pressure passes from Montana or Idaho southward across Utah and westward through southern Nevada, thence into Arizona or southern California, and if followed by a rapid rise in pressure is generally the forerunner of much colder weather in the southern citrus belt. . . . The Weather Bureau office at San Francisco has demonstrated beyond criticism that frost can be successfully forecast." A study of the frost warnings of the Bureau, with frequent observations on temperature, humidity, and air motion, will enable the grower to judge of the danger of frost in his particular case. The methods of protection discussed are, planting with more regard to air drainage and correcting defective air drainage by means of windbreaks, etc.; warming the air by means of small fires in wire baskets, smudging and the use of steam, irrigation with unheated and with warm water, spraying, and screening or covering. Many of these methods have proved of great practical value, but "of all methods proposed for the protection of fruit, excepting wire baskets, irrigation has the largest amount of evidence in its favor."

Prediction of frost, J. E. BONEBRIGHT (*Idaho Sta. Bul.* 23, pp. 136-142, figs. 3).—This article discusses briefly protection against

frosts by means of smudges, and describes a piece of electrical apparatus devised by the author to give warning of a fall in temperature.

"The apparatus consists of a battery, relay coil, alarm bell, and thermometer. The battery used is the common crow-foot cell used in telegraphing, size 6 in. by 8 in.

"The relay C (fig. 4) is composed of two coils. Each coil has an iron core $1\frac{1}{4}$ in. long, $\frac{1}{4}$ in. in diameter, and is wound with No. 24 B. and S. double cotton-covered magnetic wire, to a depth of $\frac{1}{4}$ of an inch. The coils are wound right and left handed and are placed horizontally.

FIG. 4.—Electrical apparatus for frost warning.

"The armature A consists of an upright piece with a crossbar of soft iron, which is so held that it is attracted by the iron cores of the coils when magnetized. An adjustable spring holds the armature A against the screw S when no current is flowing through the coil C. . . .

"The thermometer consists of a glass stem 8 or 10 in. long, with an internal diameter of approximately $\frac{1}{25}$ of an inch (0.1 cm.), attached to a bulb which has a diameter of 1 in. (2.5 cm.). The bulb and 2 or 3 ins. of the lower part of the tube are filled with mercury, and the tube is graduated for every 10 degrees from 30° F. to 100° F. Electrical connection with the mercury is made by a platinum wire blown in the glass. On the top of the stem is a brass cap with a No. 30 B. and S. bare copper wire passing through it and making contact with the mercury. The thermometer can be tested at any time by comparing it with an accurate Fahrenheit thermometer. It is made large in order to give free action to the mercury around the wire in the tube. . . .

"The thermometer should be freely exposed, not more than 2 or 3 ft. above the ground, in that portion of the orchard most liable to frost, usually the lower ground.

"The lower point of the copper wire in the tube of the thermometer should be set opposite the number indicating the temperature for which the instrument is to give warning, usually 40 to 45° F. A copper wire, No. 16 B. and S., connects the wire in the stem of the thermometer to one post of the bell and to one pole of the battery, another wire connects the mercury in the bulb with the proper binding post of the coil, and a third wire is run from the armature of the relay to the remaining binding post of the bell. The remaining pole of the battery is then connected to the properly marked post of the coil. . . .

"The action of the instrument is very simple. When the wire in the stem of the thermometer is in contact with the mercury a current of electricity will pass through the relay coils, causing the armature to be attached to the iron cores. The battery

furnishes a continuous current and will keep the armature in this position until the circuit is broken. When the circuit is broken by the mercury falling below the lower point of the wire in the thermometer the armature will be drawn by the spring against the screw S, which puts the bell in a circuit with the battery."

The use of the ordinary differential thermometer in the above apparatus is explained and one form of thermostat is described, but thermostats are not considered reliable for the purpose of frost warnings.

A study on hail. Protection of crops by cannonading. V. VERMOREL (*Étude sur la grêle. Défense des récoltes par le tir du canon. Montpellier: Coulet & Sons, 1900, pp. 78, figs. 14*).—This pamphlet discusses the various theories of the formation of hail, the explosives and cannon used and how the explosions operate to prevent hail, the results obtained in different countries, and the organization of stations; and gives the statutes of the cantons of Villefranche and Anse against hail, and titles of 103 papers on the subject. The author claims the results already obtained conclusively prove the effectiveness of this means of preventing destructive hailstorms. The detailed results of numerous experiments are reserved for a future publication.

Meteorological records. J. E. BONEBRIGHT (*Idaho Sta. Bul. 23, pp. 129-133*).—Monthly and yearly summaries of observations at Moscow, Idaho, on temperature, pressure, precipitation, cloudiness, and dates of latest frosts in spring and earliest in autumn during 1898 and 1899; and a summary of similar observations during 5 years (1895-1899).

The mean temperature for 1899 was 44.8° F., for the 5 years (1895-1899) 45.1°; the highest temperature for 5 years was 100°, the lowest -17°. The mean pressure for 1899 was 27.25 in., for 5 years 27.33. The rainfall in 1899 was 20.12 in., melted snow 3.35 in.; during 5 years 19.02 and 4.37 in. respectively. The average number of clear days (per year) during 5 years was 180, during 1899 171. The latest killing frost in the spring occurred May 17, the earliest in the fall October 2, in 1899; the latest frost in spring during 5 years occurred May 30, 1898, the earliest in the fall September 6, 1895.

Meteorological observations. J. E. OSTRANDER and A. C. MONAHAN (*Massachusetts Hatch Sta. Met. Buls. 136, 137, 138, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during April, May, and June. The data are briefly discussed in general notes on the weather of each month.

Report of precipitation and temperatures for the year 1899. J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 28, 29*).—A monthly summary of observations at Guelph. "The highest temperature recorded at the college for the year was 95° on August 19. The lowest was 20.5° below zero on February 12. The amount of precipitation for the year, including rain and melted snow, was very nearly 20 in."

Monthly summaries of meteorological observations made at Leon (Guanajuata) during 20 years, 1878-1897. M. LEAL (*Mem. y Rev. Soc. Cient. "Antonio Alzate," 14 (1899-1900), No. 6, p. 264*).—A summary of observations on pressure, temperature, rainfall, evaporation, humidity, cloudiness, direction and velocity of the wind, etc.

Some facts about the climate of Tennessee. W. M. FULTON (*Tennessee Sta. Bul. Vol. XIII, No. 1, pp. 13-16, charts 2*).—This article discusses briefly temperature, rainfall, and length of the growing season in different parts of the State.

The climate of our new possessions, G. MICHAUD (*Sci. Amer.*, 83 (1900), No. 11, p. 171, *dgms.* 2).

Frost protection, W. M. FULTON (*Tennessee Sta. Bul.* Vol. XIII, No. 1, pp. 3-12, *figs.* 5).—A popular discussion of how frost is formed and when to expect it, and a description of various methods of protection from frost.

Protection from lightning, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 27, 28).—Statistics of destruction of property and loss of life from lightning during a storm in August, 1899, are briefly summarized, and means of protection are discussed.

Observations on the determinations of drought intensity, G. H. KNIBBS (*Jour. and Proc. Roy. Soc., New South Wales*, 33 (1899), pp. 69-85, *fig. 1*).—A discussion of the conditions affecting soil moisture, rainfall, percolation, evaporation, etc.

Suggestions for depicting diagrammatically the character of seasons as regards rainfall, and especially that of droughts, H. DEANE (*Jour. and Proc. Roy. Soc., New South Wales*, 33 (1899), pp. 63-68, *pl. 1*).—The author briefly describes a diagram which shows not only the total yearly rainfall and its distribution by months, but also "what portion of the rainfall runs off the ground or soaks away and is available for storage and for keeping up the flow of rivers and streams."

Combination of the effects of synodic and tropic revolutions of the moon, its action on the movement of lows, A. POINCARÉ (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 2, pp. 132-135).

WATER—SOILS.

The soils of Salt Lake Valley, Utah, F. D. GARDNER and J. STEWART (*U. S. Dept. Agr., Division of Soils Circ.* 4, pp. 11).—This is a preliminary report on a survey undertaken in July, 1899, by the Division of Soils, cooperating with the Utah Station, to map the soils with particular reference to the extent of and damage from alkali and seepage waters.

A brief account is given of early irrigation in this region and of recent irrigation improvements and the results of 4 months' study of the region are briefly summarized under the following heads: Climate, water supply, soil, alkali, and drainage.

A large portion of the area examined is unfit for cultivation on account of excess of alkali salts.

"Sodium chlorid, or the common salt of commerce, forms from 50 to 97 per cent of the total salts present. Besides this, there are considerable quantities of the sulphates of soda, lime, and magnesia, chlorids of lime and magnesia, and also carbonate of soda, or true black alkali. The black alkali is nearly always present in amounts varying from a trace up to several per cent in small local spots. There is, in the aggregate, a large area in which it occurs in sufficient quantity (0.1 per cent) to be fatal to crops.

"It seems quite probable that this accumulation of salt came chiefly from two sources, i. e., from the higher lands to the south and from the waters of Great Salt Lake. It is most likely that the lake is the source of the greater portion of them, for when it was from 30 to 50 ft. higher than now, it would have submerged nearly all the area under consideration, and must have also contained much salt in solution. Upon the subsidence of the water the soil would, of course, be left heavily impregnated with salts. Besides, within the memory of the present inhabitants,

the lake has again submerged a considerable part of this area, and, according to reliable records, the lake in 1868 was 12 ft. above its present level, and at this height must have covered at least 50 sq. miles of what is now mapped as dry land. . . .

"There is only one feasible way of getting rid of the salts, and that is by providing a thorough system of underdrainage and washing them out by flooding. . . .

"Of the 125 sq. miles lying mostly north of Twelfth street road and between Salt Lake City and the lake, 90 sq. miles, or about 58,000 acres, are capable of reclamation. For this portion, tile drainage is recommended as of general application."

Some observations on soil temperatures, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, p. 26, fig. 1*).—The method of observation and the results obtained are thus described:

"Some soils in large pans were set in the open air, near a large body of water, and the temperatures of the soils, the air, and the water were observed each hour, beginning at 7 a. m. and concluding at 6 p. m. They were all exposed to the action of the sun's rays. The [temperature of] water rose from 61 to 68°, reaching 68° F. at 2 p. m. It then fell to 66° by 6 p. m. The [temperature of] air rose from 44 to 70°, reaching its highest at 2 p. m., and then fell by 6 o'clock to 63.5°. The soils all began at the same temperature as the air, namely, 44°; all the soils reached their maximum at 1 o'clock, and from that time declined rapidly. The highest temperature reached by the dark soil was 94°, by the light-colored soil 91°, and by the wet soil 80°."

The practical application of these results is briefly discussed.

Analyses of calcareous soils of Monferrato. New methods of determining easily soluble calcium carbonate, F. MARTINOTTI (*Staz. Sper. Agr. Ital., 33 (1900), No. 3, pp. 259-273; abs. in Chem. Centbl., 1900, II, No. 10, p. 593*).—The author reports determinations of moisture, organic matter, sand, clay, citrate-soluble, and total lime in 25 samples of soils, as well as tests of various citrate methods of determining the solubility of crystallized and amorphous calcium carbonate. On the basis of the results obtained he recommends the use of the neutral ammonium citrate solution for the latter purpose. For the determination of clay and sand he recommends a modified form of the Schöne apparatus, which is continuous and automatic in its operation. The adaptability of the soils examined to the American grape is discussed.

Arable soils of the Canton of Redon with respect to phosphoric acid, G. LECHARTIER (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 19, pp. 1225-1229; abs. in Jour. Chem. Soc. [London], 78 (1900), No. 452, II, p. 433*).—About half of the soils of this canton contain more than 0.1 per cent of phosphoric acid. The average percentages of this substance in soils derived from different geological formations were as follows: From granite, 0.87; pre-Cambrian, 0.90; Armorican sandstone, 0.57; Angers schist, 1.04; Poligné schist and sandstone, 1.05; and alluvium, 1.24. Phosphatic fertilizers proved beneficial even in soils containing more than 0.1 per cent of phosphoric acid. The mineral phosphates and basic slag were more effective than superphosphate.

Composition of the soils of the Canton of Redon as regards lime, magnesia, potash, and nitrogen, G. LECHARTIER (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 18, pp. 1163-1166; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 452, II, p. 432).—Analyses are reported of soils derived from granite, pre-Cambrian, Silurian, Upper Silurian, and ancient and modern alluvium formations. The average percentages of lime varied from 0.058 in Angers schist to 0.108 in Armorican sandstone soils; of magnesia, from 0.084 in granite to 0.16 in alluvial; and potash, from 0.232 in Angers schist to 0.577 in Poligné schist and sandstone. Nitrogen varied from 0.109 to 0.135 per cent.

Remarks on the sand-drift problem, J. H. MAIDEN (*Agr. Gaz. New South Wales*, 11 (1900), No. 1, pp. 12-18).—A brief report is given on the attempts which have been made to prevent the drifting of sands in two portions of New South Wales.

It was found at Newcastle that depositing ashes, cinders, and shale from collieries and tramways served to hold the sand to a marked extent. The addition of soil and manure rendered it possible to grow a number of plants.

A list of shrubs and trees suitable for seaside planting is given, together with brief notes as to their relative value. Among grasses, which are the most important of sand binders, notes are given on Bermuda grass, *Festuca littoralis*, carpet or Louisiana grass, marram grass (*Psamma arenaria*), *Saccharum arundinaceum* and *S. spontaneum*, *Spinifex hirsutus*, St. Augustine grass (*Stenotaphrum americanum*), and coast couch grass (*Zoysia pungens*).

Water and water supplies, J. G. THRESH (*Philadelphia: P. Blakiston's Son & Co.*, 1900, pp. VII + 438; *rev. in Jour. Amer. Chem. Soc.*, 22 (1900), No. 4, p. 231).—A second revised edition of this treatise.

Softening water for domestic use (*Tradesman*, 43 (1900), No. 12, p. 97).

The purification of water for household and technical purposes, O. KRÖHNKE (*Die Reinigung des Wassers für häusliche und gewerbliche Zwecke*. Stuttgart: Ferdinand Enke, 1900, Vol. V, No. 3-5, ill.).

Examination of water for sanitary and technical purposes, H. LEFFMANN (*Philadelphia: P. Blakiston's Son & Co.*, 1899, 4. ed. *rev. and enl.*, pp. 145, ill.).

Soil studies, A. M. SOULE (*Tennessee Sta. Rpt. 1899*, pp. 37-39, fig. 1).—A brief popular discussion of the physical properties of soils and their relations to moisture.

The study of sandy soils, WEISS-WITTSTOCK (*Deut. Landw. Presse*, 29 (1900), No. 69, p. 857).—A popular article pointing out the importance of farmers understanding the characteristics of their soils, especially in case of sandy soils.

Binding drift sand (*Jour. Agr. and Ind. South Australia*, 3 (1900), No. 7, pp. 552-555).—A list of plants for sand binding, with methods of planting.

Hamet Experimental Farm (*Semaine Agr.*, 20 (1900), No. 1005, pp. 261, 262).—Mechanical and chemical analyses are reported of 5 samples of soils and subsoils from this farm, which is situated at Survilliers, Seine-et-Oise, France.

How are the best arable soils derived? HABERSTROHM (*Fühling's Landw. Ztg.*, 49 (1900), No. 17, pp. 638-642).—A brief general discussion of the agencies involved in the formation of soils, the loess and chernozem soils being especially considered.

Practical utilization of soil analysis, H. LAGATU (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 35, pp. 278-284).—A general discussion of this subject.

The influence of surface cultivation on the moisture of the soil, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1899*, pp. 24, 25, fig. 1).—The experiments here described are a continuation of those of the previous year (E. S. R., 11, p. 625) and lead to the same conclusions.

Principles of plowing, A. M. SOULE (*Tennessee Sta. Rpt. 1899*, pp. 39-41).—The interrelationship between plowing and the moisture content of the soil is brought out.

Soil temperature for the growing season, J. E. BOXEBRIGHT (*Idaho Sta. Bul. 23*, pp. 134, 135).—A tabular record is given of weekly averages of soil temperatures at depths of 1 in. to 6 ft. during the growing seasons (April to October) of 1898 and 1899.

A contribution to the knowledge of nitrification, W. MIGULA (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 11, pp. 365-370; *abs. in Chem. Ztg.*, 24 (1900), No. 50, *Reper.*, p. 183).—Contrary to Ebermayer, the author found that the process of nitrification goes on in forest soils as well as in cultivated soils, varying somewhat with the depth and with the time of year.

Instructions for determining in the field the salt content of alkali waters and soils, M. WHITNEY (*U. S. Dept. Agr., Division of Soils Circ. 6*, pp. 9).—Instructions with formulas for the field standardization of the electrolytic bridge (E. S. R., 11, p. 325) in determining the salt content of soils and waters.

Available plant food, H. SNYDER (*Proc. Soc. Prom. Agr. Sci.*, 1899, pp. 91-95).—This is a discussion based mainly upon investigations by the author, which are reported elsewhere (E. S. R., 11, p. 1018), of the value of the Dyer and Goss methods for determining the available phosphoric acid in soils. The conclusion is reached that "both fail to indicate the amount of available phosphoric acid and potash. Both Dyer's method and Goss's method are without doubt applicable to certain types of soil, but they are not applicable to soils where a large part of the plant food exists in organic forms."

FERTILIZERS.

The storage of stable manure, F. HOLDEFLEISS (*Mitt. Landw. Inst. Breslau. 1900*, No. 3, pp. 49-55; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 454, II, p. 571).—In continuation of previous experiments (E. S. R., 11, p. 828), the author studied the gains or losses of different constituents in 3 lots of manure kept (1) without preservative, (2) with the addition of potassium salt, and (3) with superphosphate. The preservatives reduced the loss of proteid nitrogen and increased considerably the amount of nitrogen in the form of ammonia. Of the nonnitrogenous constituents the pentosans were most readily decomposed. In case of crude fiber free from pentosans there was a loss of 17.5 per cent in one instance and gains of between 7 and 8 per cent in other instances.

Economy in the use of barnyard manure, W. SAUNDERS (*Proc. Soc. Prom. Agr. Sci.*, 1899, pp. 47-52).—This is a discussion of this subject based upon the results of experiments during 11 years at the Central Experimental Farm at Ottawa, Canada (E. S. R., 11, p. 833). These experiments were designed mainly to test the relative merits of barnyard manure when applied to different crops fresh from the barnyard, as compared with the same material rotted. The data obtained in experiments with spring wheat, barley, oats, corn, mangel-wurzels,

turnips, carrots, and potatoes are tabulated and discussed. The conclusion drawn from this data is that if farmers would preserve "all the liquids with the solids in water-tight troughs behind the animals, using cut straw for bedding and as an absorbent; then distribute this over the land in a fresh condition before any of the liquids so rich in fertilizing constituents are decomposed, the saving effected would be enormous, and the value of barnyard manure in bringing increased crops would probably be nearly double what it now is."

The reduction of nitrates in the presence of barnyard manure, J. P. STREET (*New Jersey Stat. Rpt. 1899, pp. 86-96*).—Previous investigations on the subject are briefly noted, and an account is given of a study of the changes in the nitrogen of a mixture of fresh solid cow manure (about 30 gm.) with nitrate of soda (1.25 gm.), with sulphate of ammonia (1 gm.), and with dried blood (1.5 gm.), with or without the addition of gypsum, acid phosphate, kainit, and sulphur (each 0.2 gm.), and carbon bisulphid (20 cc.). The volume was in each case made up to 300 cc. with water and the mixtures kept in open flasks in the laboratory at about 20° C. from February 28 to March 29, with occasional shaking. Two series of experiments were made—one being examined for nitrates by the Schulze-Tiemann method at intervals of 7, 14, and 24 days, the other remaining undisturbed until the end of the period. In case of the mixture of manure and nitrate denitrification was complete in 24 days; with other substances added to this mixture, the periods of denitrification were as follows: With gypsum 27 days, acid phosphate 27 days, kainit 16 days, and sulphur 23 days. The mixture sterilized with carbon bisulphid lost only 9.6 per cent of its nitrates in 24 days.

In case of sulphate of ammonia the changes in the nitrogen were slight, the greatest loss in 24 days being 4.1 per cent where acid phosphate was used. There was a slight gain in case of kainit and gypsum.

The examination of the second series of tests showed approximately the same results as the first as regards the nitrate.

"The loss where kainit was used was complete, as it was before, while the nitrate alone and nitrate with acid phosphate suffered a loss of over 97 per cent. The losses where sulphur and plaster was used were somewhat less, being 93.7 per cent and 85.4 per cent, respectively. The plaster seemed in this test to have a slight retarding effect on denitrification. The loss where carbon bisulphid was used, while more than in the first series, was only about one-fourth of that sustained by the other tests."

In the sulphate of ammonia tests, the changes in nitrates and total nitrogen were comparatively insignificant. There was a considerable gain in soluble organic nitrogen in every case, being most pronounced where carbon bisulphid and sulphur were used. This was also true of the nitrate series. There was also a marked gain in insoluble organic nitrogen in the sulphate of ammonia tests, being largest where the sulphate was used alone and least where carbon bisulphid was used.

Considerable amounts of free ammonia were formed during the fermentation, especially in the sulphate of ammonia tests in which kainit was used. In the dried blood tests all of the nitrates and combined ammonia were lost. Kainit appeared to have had a strong influence in liberating ammonia, causing a loss of over 26 per cent of the total nitrogen present. Carbon bisulphid on the other hand exerted a retarding influence in this respect.

Investigations relative to the use of nitrogenous materials, E. B. VOORHEES (*New Jersey Stas. Rpt. 1899, pp. 97-120*).—A review is given of literature relating to denitrification and the changes which may occur in the nitrogen of barnyard manure, and investigations relating to the composition, and the availability of the nitrogen of solid and liquid manure are reported.

The solid and the mixed solid and liquid excrement (without litter) of a well-fed cow were analyzed when fresh and after being exposed to fermentation and leaching in the open air in 100 lb. lots from February 4 to June 15. In that time the weight of the solid manure was reduced to 50 lbs., the mixed solid and liquid manure to 61 lbs. The composition of the fresh and leached manure, calculated to a water-free basis, was as follows:

Composition of manures on water-free basis.

	Fresh manure.		Leached manure.	
	Solid.	Solid and liquid.	Solid.	Solid and liquid.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Ash	12.166	12.924	14.161	15.282
Organic matter	87.834	87.076	85.839	84.718
Nitrogen (total)	2.286	3.553	2.489	2.529
Nitrogen soluble in water583	1.876	.377	.734
Nitrogen as nitrates101	.013	.058	.014
Nitrogen as ammonia248	1.070	.182	.521
Nitrogen soluble organic234	.793	.137	.199
Nitrogen insoluble organic	1.703	1.677	2.112	1.795
Phosphoric acid	2.915	2.582	1.408	1.617
Potash	1.488	2.331	.584	1.062

In the solid manure there was a loss by leaching of 46 per cent of nitrogen, 72 per cent of phosphoric acid, and 80 per cent of potash; in the mixed solid and liquid manure 57 per cent of nitrogen, 62 per cent of phosphoric acid, and 72 per cent of potash.

The availability of the nitrogen of fresh and leached solid and mixed solid and liquid cow manure used alone or in connection with nitrate of soda, sulphate of ammonia, and dried blood was tested in a series of experiments with corn and tomatoes grown in cylinders (without bottoms) 23½ in. in diameter, and 4 ft. long, sunk in the ground. The soils used were made as uniform as possible—a medium clay for the corn, a sandy loam for the tomatoes. The applications of manure were larger than are usual in practice, but not excessive, the largest application being about 20 tons per acre. The results of the corn experiments

are reported. These show that in every case there was a decided gain in weight of dry matter due to application of the nitrogenous fertilizers. There was also a considerable but more variable gain of nitrogen. The comparative availability of the nitrogen in the different forms of the manure as shown by these experiments was as follows:

Comparative availability of nitrogen in cow manure.

Character of manure.	Nitrogen recovered.	Increase in dry matter.	Increase in dry matter on basis of nitrogen in unleached manures.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Fresh manures:			
Solid	7.44	15.4	
Solid and liquid	22.04	59.4	
Leached manures:			
Solid	16.80	33.0	23.2
Solid and liquid	22.36	36.1	36.1

"The yields, when the various forms of yard manure are applied, together with nitrates in different quantities as well as with ammonia and dried blood, show one thing very clearly, viz, that the total recovery of nitrogen is in every case greater where the different materials are used together than when they are used singly. . . .

"It is also shown that the losses are not very different when the manure is used with the small or the large amount of nitrate of soda, which would seem to argue that the nitrogen was not dissipated by denitrification, but that the losses were due to other causes."

The relative availability of the nitrogen in the artificial forms and in the various kinds of cow manure, based upon recovery of nitrogen in the crop, is shown in the following table:

Relative availability of nitrogen in different forms.

	<i>Per cent.</i>
Nitrate of soda	100
Sulphate of ammonia	99.5
Dried blood	95.4
Solid manure, fresh	16.76
Solid manure, leached	37.86
Solid and liquid manure, fresh	49.66
Solid and liquid manure, leached	50.38

A summary is given of the results of experiments with nitrogenous fertilizers in different parts of New Jersey, which have already been published in a bulletin of the station (E. S. R., 11, pp. 439, 440, 444).

Experiments on the fertilizing effect of the phosphoric acid of bone meal, O. KELLNER and O. BÖTTCHER (*Deut. Ländw. Presse*, 27 (1900), No. 52, pp. 665, 666; *abs. in Chem. Ztg.*, 24 (1900), No. 82, *Repert.*, p. 22).—This is an account of experiments with summer rye grown in pots containing 6 kg. of a moderately compact loam soil with 1.91 per cent of humus and a very small amount of lime. Ten samples of partly degelatinized bone meal were compared in these experiments with superphosphate and Thomas slag with and without the addition of lime (carbonate). The results indicate that on soils which are not

abundantly supplied with calcium carbonate the phosphoric acid of bone meal has an important value especially for fall application. The bone meal, however, should not be applied on freshly limed soils or on those which are by nature rich in lime. The unfavorable results obtained by Wagner and Maercker with bone meal are attributed to the fact that these investigators experimented on soils which were rich in lime or had been recently limed.

Fertilizers (*New Jersey Stat. Rpt. 1899, pp. 17-85*).—This is mainly a reprint of Bulletin 139 (E. S. R., 11, p. 829), with the addition of statistics of the fertilizer trade in New Jersey during 1898 and thirteen preceding years, the market prices of fertilizers, text of the fertilizer law, and lists of inspectors and of manufacturers whose goods were inspected in 1899. From data furnished by 92 out of 109 firms selling fertilizers in New Jersey in 1898 it is estimated that the total consumption of fertilizers in the State was 60,094 tons, valued at \$1,569,061, in 1898, as against 56,172 tons in 1897. "The complete manures represent 70 per cent of the total number of tons sold in 1898 and 77 per cent of the total values of all sales." It will thus be seen that the farmers of the State paid over \$1,200,000 for complete manures during 1898. The statistics reported show that there has been a decline in the prices of complete fertilizers from 1885 to 1898, but that this decline in price has not been accompanied by a corresponding decrease in the absolute amounts of plant food delivered to consumers.

Some principles in the use of fertilizers, C. A. MOOERS (*Tennessee Sta. Rpt. 1899, pp. 46-50, fig. 1*).—A general discussion.

Suggestions for the use of barnyard manure, C. WELLINGTON (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 301-315, pl. 1*).—A general discussion of this subject under the following heads: What barnyard manure is made of, how it compares with other manures, how to make it, and how to use it.

On the fertilizer valuation of sewage, W. BRESLER (*Deut. Zuckerind., 25 (1900), No. 34, Sup. 1, pp. 1338, 1339*).—Brief descriptions are given of various methods which have been proposed for estimating the fertilizing value of the sewage from cities and factories of various kinds.

Fertilizer inspection, C. D. WOODS (*Maine Sta. Bul. 60, pp. 23-30*).—"This bulletin contains the analyses of manufacturers' samples of brands of fertilizers licensed before March 7, 1900," accompanied by brief statement of the chief provisions of the State fertilizer law. The number of analyses reported is 131.

Analyses of commercial fertilizers sold in Maryland, H. B. McDONNELL ET AL. (*Maryland Agr. Col. Quart., 1900, No. 9, pp. 55*).—This bulletin contains a schedule of trade values of fertilizing materials, tables of analyses and valuation of 404 samples of fertilizers examined from March to July, 1900, inclusive, and a list of fertilizers licensed for sale in the State during the year ending February 1, 1901.

The composition and economical use of commercial fertilizers, H. J. WHEELER (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 131-169*).—A very thorough general discussion of this subject.

Cooperative experiments with fertilizers, C. A. MOOERS (*Tennessee Sta. Rpt. 1899, pp. 53-56*).—A plan of cooperative experiments in different parts of the State under supervision of the station is described.

Perchlorate in nitrate of soda, F. W. DAFERT (*Oesterr. Chem. Ztg.*, 3 (1900), No. 15, pp. 369, 370).—Examinations of a number of old samples of nitrate of soda as well as various museum specimens of crude nitrate, etc., are reported, which show that in only two of the old samples of nitrate was perchlorate present, while none of the museum specimens contained this substance. From these facts the author concludes that perchlorate is an impurity which has appeared in nitrates only in recent years.

Chemical fertilizers, DE COQUET (*Engrais chimique*. Paris: J. B. Baillière & Sims, 1899).

Decomposition of bone meal by micro-organisms, J. STOKLASA (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 16, pp. 526-535, fig. 1; *Böhm. Ztschr. Zuckerind.*, 24 (1900), p. 627; *abs. in Chem. Ztg.*, 24 (1900), No. 68, *Repert.*, p. 244).—The results of a series of laboratory and plant-house experiments are reported, which show that the bacterial action in decomposing bone meal varies with the kind of organism and with the kind and amount of carbohydrates present. The practical application of the results is discussed.

FIELD CROPS.

Grain experiments: Surface and subsoil or underground moisture, A. E. SHUTTLEWORTH (*Ontario Agr. Col. and Expt. Farm Rpt. 1899*, pp. 44-48, fig. 5).—In these experiments, surface soil from a field in which roots had been grown the preceding year, was thoroughly mixed and used in 10 galvanized iron cylinders, 12 in. in diameter and 3 ft. long, and so constructed that water could be applied from the bottom in imitation of underground moisture. The cylinders were placed in 2 parallel rows. A cotton sheet containing circular holes was stretched over them in such a way that only the surface of the soil was exposed to the sun. Oats, barley, wheat, and peas were grown. One cylinder of each was subwatered, while the duplicate pots were surface watered. The surface-watered oats required 43 lbs. of water from the time they were sown until maturity; barley, 38.5 lbs.; wheat, 29.75 lbs.; and peas, 28 lbs. The water required for maturing the crops in the subwatered cylinders was as follows: Oats, 65.25 lbs.; barley, 25.5 lbs.; wheat, 34.25 lbs.; and peas, 104 lbs. The total yields, including grain, straw, and roots, obtained in the different pots are shown in the table below:

Yield of crops grown in surface and subwatered cylinders.

	Oats.	Barley.	Wheat.	Peas.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Surface watered	67.66	45.39	29.95	63.32
Subwatered.....	82.39	45.34	26.62	116.60

The surface-watered oats ripened 4 days earlier than the subwatered, but the yield of both grain and straw was considerably less. In the case of barley there was little difference in growth, maturity, and yield between surface-watered and subwatered pots. The results in this case are interpreted as showing the necessity of surface moisture,

and hence the desirability of fall plowing for barley. The root development of wheat in the subwatered pot was somewhat better than in the surface-watered pot but it is thought that the yield would have been greater had the crop in the subwatered pot not been injured by blight. Peas developed especially well in the subwatered pot.

On variations in plants with special reference to the relation between the grain weight and the nitrogen content of barley, W. JOHANNSSEN (*Medd. Carlsberg Lab., 1899, No. 4, pp. 228-313*).—Experiments are reported with Carter Goldthorp barley which were made with the object of producing a strain especially low in nitrogen, but having a large and plump grain, to meet the requirements of a good malting barley. In the fall of 1893, 500 practically perfect heads of this variety were picked from 8 different places in a barley field, out of which the best 86 heads were chosen to form the foundation stock for the study. Five kernels on the same side of each head were taken for analysis and their weights and nitrogen contents determined in case of each head. The average weight per kernel ("grain weight") for all 86 samples was 62.28 mg., and the average nitrogen content 1.606 per cent. By grouping the results as to the grain weight, a marked increase in the nitrogen content was found with increasing grain weight.

In 1894 the kernels from a number of the best heads were sown separately and at harvest 185 of the largest and finest heads were analyzed as in the previous year. The average grain weight was 54.24 mg., and the average nitrogen content 1.489 per cent. Here again the nitrogen content increased, as a rule, with the weight of kernel, although there were exceptions to this general rule in about 30 per cent of the cases.

About 50 heads from the crop of 1894 served as seed in 1895, selected mostly from the exceptions mentioned above, and this was repeated the two following years. Through systematic selection of heads with heavy kernels and low nitrogen content for 3 generations, a progeny was obtained in the fourth generation, samples of which were characterized by a somewhat higher average grain weight and an appreciably lower nitrogen content than that found in the rest of the crop. The following summary shows the results obtained with 2 samples and their progeny:

Grain weight and nitrogen content of barley from selected seed.

Year.	Average for year.			Sample 13 and progeny.			Sample 182 and progeny.		
	Number of samples.	Grain weight.	Nitrogen content.	Number of samples.	Grain weight.	Nitrogen content.	Number of samples.	Grain weight.	Nitrogen content.
		<i>Mg.</i>	<i>Per cent.</i>		<i>Mg.</i>	<i>Per cent.</i>		<i>Mg.</i>	<i>Per cent.</i>
1894.....	173	54.3	1.490	54.8	1.310	56.6	1.430
1895.....	515	45.0	1.510	3	47.6	1.413	4	46.8	1.413
1896.....	347	56.0	1.680	4	59.4	1.630	6	59.4	1.650
1897.....	140	51.4	1.606	10	57.3	1.612	16	49.0	1.487

The average of 26 samples of 182 grown in 1897 was a grain weight of 52.2 mg. and a nitrogen content of 1.535 per cent, while the average of all other samples grown that year was 51.3 mg. and 1.622 per cent.

The results would seem to justify the conclusion that the correlation between grain weight and nitrogen content can be disturbed by systematic selection, and can not, therefore, be of paramount importance in the improvement of plants. Correlations were found between the length of head and the grain weight (the latter increasing with the former), and between length of head and nitrogen content (the latter likewise increasing with the former). But these correlations are still less fixed than that of the grain weight and the nitrogen content. The length of head and the number of kernels in the head, on the other hand, stand in a much closer relation than the preceding factors, although in the author's opinion a perfect correlation does not exist even here.

The theory of the incompatibility of valuable qualities in cultivated plants, especially emphasized by Schindler and von Proskowetz, according to the author, has but slight scientific importance, while, viewed from a practical standpoint, it is only an expression of the fact that certain ends aimed at in the improvement of crops are more difficult to reach than others. Practical experiences must be carefully scrutinized before they are used for the support of the principle of heredity and variability. In the point under discussion one must be particularly on the lookout for complications brought about by external conditions, the confounding of which with correlation phenomena may cause considerable confusion.—F. W. WOLL.

Some investigations of the relation of the size of grain to the nitrogen content of wheat and peas, W. JOHANNSEN and F. WEIS (*Tidsskr. Landbr. Plantearb.*, 5 (1899), pp. 91-100).—The investigations were conducted with 5 different kinds of wheat, viz. Sonne Extra Squarehead, Bahlson Squarehead, Urtoba Peters, Urtoba Metz, and Light-colored East Prussian wheat. The results obtained show that the different kinds of wheat grown in Denmark agree with the two-rowed barley in the relation between grain weight and percentage of nitrogen; as a general rule the percentage of nitrogen is increased with increasing grain weight, but there are many exceptions to the rule, so that this can not be used as an absolute starting point in studies of plant improvement.

In a supplement to this paper, W. Johannsen shows that this statement also holds good in case of Victoria peas. Ten large peas had an average weight of 0.450 gram, and an average nitrogen content of 3.35 per cent, against a grain weight of 0.226 gram and a nitrogen content of 3.17 per cent for 10 small peas. The average of 20 determinations was: Grain weight, 0.338 gram; nitrogen content, 3.26 per cent.—F. W. WOLL.

Report of the experimentalist, C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 101-129*).—The experiments here reported consist largely of variety tests and are in continuation of the work reported in 1898 (*E. S. R.*, 11, p. 628). The work recorded covers experiments with oats, winter and spring wheat, barley, rye, buckwheat, Indian corn, teosinte, grasses, millet, sachaline, prickly comfrey, spurry, yarrow, potatoes, field roots, chicory, rape, kale, cabbage, white mustard, field peas, cowpeas, grass peas, Egyptian peas, *Lathyrus sylvestris*, field beans, soy beans, horse beans, velvet beans, clover, alfalfa, sanfoin, vetch, lupines, lentils, serradella, peanuts, flax, hemp, ramie, chufas, pumpkins, squashes, and sunflowers.

The Joannette heads the list as regards yield of oats. It is a black variety, possessing a very short straw, suitable for growing only on lands which naturally produce a large amount of straw. It stools abundantly and should not be seeded at a rate greater than 4 pecks per acre. The crop should be cut while somewhat green to avoid shelling. White Siberian stands next on the list. It is the most extensively grown and popular oat in Ontario, and has made the highest average record of all the oats grown in cooperative tests for 7 years.

In the fall of 1898, 87 varieties of winter wheat were sown at the station. Many of the varieties winter-killed. The hardiest varieties were Tasmania Red, Red Velvet Chaff, Red Wonder, Prize Taker, Standard, Soules, Siberian, Dawson Golden Chaff, Pride of Genessee, and Early Arcadian, mentioned in the decreasing order of merit. Dawson Golden Chaff has given the largest yield of 70 varieties tested for 5 years, with Early Genessee Giant a close rival. These, with the American Bronze, possessed the stiffest straw of the large yielders. Winter wheat that does not lodge until cut has produced a crop more than double the value of the lodged grain. Large, plump grains have given better results for seeding than those which were small, shrunken, or broken. As catch crops preceding winter wheat, peas have given the best results and buckwheat the poorest. The largest yield of grain and the best quality of seed have been obtained by allowing the grain to ripen fully. Copper sulphate and hot water treatment have been found effective in combating stinking smut.

The trials of common varieties of spring wheat show greatest yields from Red Fife, Herison Bearded, Saxonka, and Wellman Fife. Spring wheat with a solid straw has been tested and some varieties have exceeded in yields the common kinds. By far the largest yield in the solid straw varieties was given by Wild Goose, a hard wheat yielding a yellow flour. During the last 3 years there has arisen a demand for this wheat for shipment to Italy for manufacturing macaroni, so that at present it commands a higher price than the finer varieties.

In tests of 200 varieties of corn grown at the station during the past 3 years Mammoth Cuban and Mastodon Dent have been found well

adapted to the warmer soils of southern Ontario. Wisconsin Earliest White Dent for southern and central Ontario, and Salzer North Dakota, Compton Early, and King Phillip for central and northern Ontario.

In experiments with grass mixtures for pasture or hay the best and most permanent mixture has consisted of 4 lbs. of orchard grass, 4 lbs. of meadow fescue, 3 lbs. of tall oat grass, 2 lbs. of timothy, 2 lbs. of meadow foxtail, 5 lbs. of alfalfa, 2 lbs. of alsike clover, 1 lb. of white clover, and 1 lb. of trefoil. The yield from this mixture has averaged 3.6 tons per acre. Fringed brome grass alone has averaged 3.9 tons of hay per acre during a period of 5 years. Teosinte, sachaline, prickly comfrey, spurry, *Lathyrus sylvestris*, cowpeas, velvet beans, tufted and kidney vetches, crimson clover, lupines, lentils, serradella, and ramie have thus far proven unprofitable crops for Ontario.

Extensive variety tests of potatoes for a number of years lead to the recommendation of Empire State, American Wonder, Pearl of Savoy, and Rural New Yorker No. 2 as the best varieties for general cropping in Ontario. Of the Swedish turnips grown Hartley Bronze Top and Buckbee Giant are recommended. The Wisconsin Blue pea has been found identical with the Striped Wisconsin Blue, and the Small Canadian Blue identical with the Prussian Blue.

Alfalfa seems adapted to certain sections of Ontario, but is not generally satisfactory. Hairy vetch has averaged 10.2 tons of green crop per acre, which is about $2\frac{1}{2}$ times as much as the yields obtained with common spring vetch (*Vicia sativa*). Some of the earlier varieties of peanuts have been grown to perfection on the sandy loam soils in the warmest portions of the Province. Russian flax has given the best yields of seed per acre. Chufas have averaged 22.6 bu. per acre at the station. Black Giant and Mammoth Russian have proven the best yielding varieties of sunflowers. Rennie Yellow Mammoth Squash produced the heaviest yield of pumpkins and squashes tested, followed by Thorpe Mammoth Pumpkin and Mammoth Bright Red Etampes.

Turkestan alfalfa, P. B. KENNEDY (*U. S. Dept. Agr., Division of Agrostology Circ. 25, pp. 20*).—A report relative to the growth and value of Turkestan alfalfa (*Medicago sativa turkestanica*), imported and distributed by this Department in 1898 and 1899. Notes on the natural condition of the soil and climate of Russian Turkestan, the native home of the Turkestan alfalfa distributed, are given.

Out of 466 reports received relative to its value, 237 indicate some superiority over the common alfalfa. Many of the reports from experiment station workers and others in the different States as regards results secured are quoted:

“The reports from the region west of the Mississippi River and north of Kansas and California indicate that this variety is hardier and more productive than that commonly grown in this region. It seems to endure drought better, is not so easily

affected by freezing, and gives better results on strongly alkaline soils. In the East, however, where there is a heavy rainfall and where heavy soils predominate, this variety seems to be little, if any, superior to the French or Chilean varieties; in fact, it seems certain that, in some localities at least, it is less valuable. In the South so few tests have been made that no definite conclusions can be drawn, the reports from some sections being favorable to the Turkestan alfalfa, while those from others indicate that the commonly grown varieties are the most valuable. In the extreme Southwest the results are as yet quite contradictory, and further experimentation is needed.

"The seed of Turkestan alfalfa will germinate much quicker and the plants start into growth earlier under the same conditions than common alfalfa. The plants are more leafy, grow more rapidly, and have a stronger, more vigorous root system. Another advantage which the Turkestan variety has is that the stems are more slender and less woody, the plants making a more nutritious hay of finer quality. That it will withstand drought under the same conditions better than ordinary alfalfa seems certain from the reports of the experimenters. In the West and Northwest, at least, it seems to be more productive, both with and without irrigation."

Experiments with three varieties of corn, C. B. LANE (*New Jersey Stas. Rpt. 1899, pp. 201, 202*).—The relative value of Southern White, Leaming, and Early Klondike field corn and their adaptability to the soil and climate of the station were studied. The results as regards yield of stover and grain are shown in tabular form. "The Southern White variety gave highest yields of both corn and stover, although the proportion of cobs to shelled corn was 24 per cent, or 7 per cent higher than the Leaming and 8 per cent higher than the Klondike." The total yield of ears of this variety was 133 bu. per acre. Leaming variety yielded 115 bu. per acre and Klondike 91 bu. per acre.

Fertilizer experiments with corn on washed land, C. A. MOOERS (*Tennessee Sta. Rpt. 1899, pp. 51-53*).—Corn was grown in 1899 on land that had lost the greater part of its surface soil by an overflow of the Tennessee River in 1875. Nitrate of soda and muriate of potash at the rate of 160 lbs. each per acre, and double this amount of acid phosphate, were used alone and combined in two's and three's as fertilizers. Stable manure at the rate of 5,000 lbs. per acre was used in some instances, combined with either potash, acid phosphate, or both. The results are tabulated and the profit or loss on the different plats calculated. The largest yield per acre, 32.4 bu., and greatest net profit, \$3.55, were obtained from the plat fertilized with stable manure and acid phosphate.

The ratio of stover to corn on the different plats was especially investigated. On the plat without fertilizer, the ratio was in the proportion of 3:1. This unusually wide ratio was not due to large stocks but to sterility, due in a large measure to deficiencies of nitrogen and phosphoric acid in the soil, as was shown by analyses of the soil from productive and nonproductive ear-bearing plats. A smaller amount than usual of these same elements was also found in the nonbearing stalks when analyzed.

Fertilizer experiments with cotton, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 3, pp. 16, figs. 3*).—Experiments were made in growing cotton with commercial fertilizers on a soil so exhausted and worn out that cowpeas failed to make a fair growth upon it. Sixteen tenth-acre plats divided into 2 equal series were used in the experiments. The series were duplicates except that one received burnt lime at the rate of 2,000 lbs. per acre. All the plats were plowed deep and well prepared. Nitrate of soda was used at the rate of 200 lbs. per acre, acid phosphate at the rate of 600 lbs. per acre, and muriate of potash at the rate of 120 to 240 lbs. per acre. These fertilizers were used in combinations of two's and three's. In one instance sulphate of potash was used at the rate of 240 lbs. per acre for comparison.

Sweet potatoes were grown on the plats the first year, and cotton the second. Nitrogen was again added to the plats the second year, but none of the other fertilizers. The yield of seed cotton on the fertilized plats of the unlimed series averaged about 6 times that from the unfertilized plats of the same series; and the yield on the unfertilized limed plats was more than double that of the unfertilized plats of the unlimed series.

Lime used in connection with other fertilizers seemed to have no special effect on the yield. In these experiments the combination of 120 lbs. of muriate of potash and 200 lbs. of nitrate of soda gave the largest net money returns. All combinations, however, were used at a profit except possibly the plat which was fertilized with phosphoric acid and nitrogen. Sulphate of potash gave slightly better results than muriate. Phosphoric acid used with potash and nitrogen decreased the yields. Doubling the amount of potash in the formula increased the yields of seed cotton 102 lbs. per acre.

Notes on cowpea tubercles, C. B. LANE (*New Jersey Stas. Rpt. 1899, pp. 200, 201, pl. 1*).—The third successive crop of cowpeas is reported upon. The first season but few tubercles were noted and the yield of forage was 6.56 tons per acre. The second year the tubercles were more abundant and the yield of forage per acre is reported at 7.19 tons. The third season the tubercles grew abundantly and the yield of forage per acre is given at 10.02 tons. The fertilizer applied the third season was less than one-half the amount applied the second, and it is believed that the increase is due in a large measure to a greater abundance of tubercles.

A special experiment with forage crops, C. B. LANE (*New Jersey Stas. Rpt. 1899, pp. 196-199*).—The value for forage of a number of plants not commonly grown at the station was tested. The crops were grown on one-twentieth acre plats and consisted of 3 varieties of corn, Yellow and Rural Branching doura, Early Orange and Early Amber sugar cane, Red and White Kafir corn, teosinte, Evergreen

broom corn, Dwarf Essex rape, cowpeas, soy beans, and velvet beans. The yield obtained on each plat, nutrients per acre, and character and value of each crop are noted.

The Evergreen broom corn produced the highest yield of total nutrients per acre. Its high percentage of fiber and the fact that it is not readily eaten by stock make it an undesirable forage crop. Corn, on account of its succulence, palatability, and total food value is placed at the head of the list. The douras are not as desirable a forage crop as corn because they are not so palatable. Velvet beans, while rich in protein and readily eaten by stock, are too expensive as regards seed to occupy a place in a forage crop rotation at the station. The low yield obtained with soy beans prevents their recommendation as a general forage crop. Dwarf Essex rape, while rich in protein, can not be recommended for the dairy because of the flavor it imparts to the milk. It is considered admirably suited for sheep and hogs.

"The sugar canes, Kafir corns, and teosinte do not possess any marked advantages over Indian corn, and are found to be much inferior in yields of nutrients per acre. The cowpea stands lower in total nutrients than many of the other crops, but it is valuable because of its palatability and the high percentage of protein it contains."

Cooperative experiments with grasses and forage plants, P. B. KENNEDY (*U. S. Dept. Agr., Division of Agrostology Bul. 22, pp. 86, pls. 13, fig. 1*).—A tabular register is given of the different grass and forage plant seeds distributed throughout the United States and foreign countries for the fiscal years 1897–1899, inclusive. Of 251 varieties of seeds sent out, reports of investigators are presented covering 40 of these. These reports are from many States and discuss soil, planting, harvesting, ripening, yield, quality, and value of the plants for the different localities.

The varieties of plants most extensively distributed were Turkestan alfalfa, blue grama, burr clover, Dwarf Essex rape, hairy vetch, Japanese barnyard millet, meadow fescue, Metcalfe bean, Russian clover, rescue grass, Rhode Island bent grass, shad scale, smooth brome grass, slender velvet grass, side oats grama, soy beans, sorghum, sulla, velvet bean, and Virginia lime grass.

Kafir corn, H. M. COTTRELL, D. H. OTIS, and J. G. HANEY (*Kansas Sta. Bul. 93, pp. 29–48, figs. 4, maps 2*).—A popular bulletin summarizing the results of cultural and feeding experiments with this crop at the station. The feeding experiment is noticed elsewhere (p. 375).

Two varieties of Kafir corn are grown in Kansas, the red and black-hulled white. The latter has proven the more profitable at the station. In three-year comparative trials Kafir corn was found to be superior to rice corn, Jerusalem corn, and millo maize. The averages of 11 years show a production of Kafir corn of 46 bu. per acre, and of corn 34.5 bu. per acre.

The results of observations are given on seeding, cultivating, harvesting, and threshing Kafir corn, and the danger to stock when grazing on second growth, and other objections to Kafir corn are discussed. Statistical maps of the State are shown, and from the facts presented advice is given on growing Kafir corn in different parts of the State.

Fertilizer experiment with potatoes, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul.* 65, pp. 127-134).—The object of the experiment was to compare the effect upon the yield of potatoes of similar amounts of nitrogen applied alone and in combination in the form of nitrate of soda, sulphate of ammonia, and dried blood; also to test the influence of potash applied as sulphate and as muriate and a combination of equal amounts of the two. The fertilizers were applied in the drill at the rate of 1,500 lbs. per acre, containing nitrogen, 4.7 per cent; potash, 9.3 per cent; and phosphoric acid, 9.3 per cent.

As the sole source of nitrogen for potatoes, dried blood ranked first, followed by nitrate of soda and sulphate of ammonia. The best combination for nitrogen appears to be either two-thirds dried blood and one-third nitrate of soda, or else equal parts of the three fertilizers mentioned. Experiments at this station have shown that on extremely acid soils dried blood is only about one-half as assimilable as it should be. Such soils should be limed in order to get the full benefit of this fertilizer.

As a source of potash, the high grade sulphate proved somewhat superior to the muriate. There was a net gain from using the sulphate even after deducting the higher cost. However, better results at less expense were obtained by applying the potash in equal amounts of sulphate and muriate.

Soil inoculation for soy beans, H. M. COTTRELL, D. H. OTIS, and J. G. HANEY (*Kansas Sta. Bul.* 96, pp. 97-116, pls. 6, *diagms.* 2).—The preliminary experiments reported herewith on root tubercles and their production by inoculation have been abstracted from another source (E. S. R., 10, p. 119). This earlier work showed that inoculating soil for soy beans was entirely practicable. Experiments were therefore undertaken to extend the work under field conditions. Beans were (1) inoculated with a water extract of infected soil; (2) with the mud which remained after the extract had been decanted; (3) were drilled in with 150 to 750 lbs. of inoculating soil per acre; and (4) planted and inoculated soil sown broadcast over the field, both before and after seeding, at rates of 100 to 1,000 lbs. per acre. "The only satisfactory results were obtained by drilling the infected soil with the seed." No tubercles developed when the infected soil was sown broadcast. "In a plat inoculated with Massachusetts soil 2 years before, 20 plants bore 136 tubercles. . . . In another plat inoculated Massachusetts soil was spread thickly in the bottom of the drilled fur-

row and the seed dropped in it. Twenty plants in this plat bore 509 tubercles on their roots."

In another experiment soy beans were planted on a field of $11\frac{1}{2}$ acres which had been inoculated with infected soil at the rate of 1,000 lbs. per acre sown broadcast and harrowed in. "A careful examination of hundreds of plants in this field failed to show a single tubercle, and this method with the quantity of soil used is a total failure." In a later experiment 46 acres were inoculated with infected soil applied in the row by the use of a fertilizer attachment on the drill. "The results were satisfactory, nearly all plants bearing a large number of tubercles."

The value of tubercles on the roots of soy beans lies largely in the increased amount of nitrogen obtained from the air which they leave in the soil for succeeding crops. Even when the soil is not inoculated and no tubercles develop on the roots, the crop is still considered a desirable one to grow in rotation, both for those who own the land and for renters, because of its strong root system, drought-resisting qualities, and the large amount of protein furnished by the crop.

Directions for growing tuberculous-rooted soy beans on a small scale for the purpose of obtaining a supply of inoculated soil are given.

Sugar-beet experiments during 1899, A. J. McCLATCHIE (*Arizona Sta. Bul. 31, pp. 263-272, fig. 1*).—These experiments on the station farm near Phoenix were made mainly to study the question of irrigation for the sugar beet. Incidentally data were secured on the limits of the season, best time to sow and harvest, and on the changes taking place in the beet during the time of ripening.

It was found advisable to irrigate the land before seeding and again when the plants were two or three months old. Excessive irrigation should be guarded against. While too much water increased the yield, it greatly reduced the percentage and total yield of sugar.

Beet seed germinated fairly well in the locality from September to May. A good stand may be secured without irrigation from December to March. The best results from winter-sown beets were obtained from a sowing made the latter part of January. Fair results were obtained in heavy soils from seeding as late as the first of April. Winter-sown beets improve in quality until the end of July, when they usually begin to deteriorate. Beets grown after beets resulted in a decreased yield.

Sugar beets, 1899, J. T. WILLARD and R. W. CLOTHIER (*Kansas Sta. Bul. 94, pp. 49-55*).—Sugar beets were grown by 40 growers throughout the State and samples sent to the station for analysis. The data for the analyses are given in the usual tabular form. The average results obtained were not as good even as those obtained in previous years (E. S. R., 10, p. 346), the percentage of sugar in the juice averaging 10.89 and the purity coefficient 73.4. The author states

that "the results of the past 3 years confirm those of former years and indicate that while Kansas has produced many individual plats of excellent quality, she has produced more of inferior quality, and that States in higher latitudes are better situated for successful sugar-beet production."

Plans for growing sugar beets in 1900 in given localities are added, together with directions for growing sugar beets.

Sugar-beet investigations for 1899, J. L. STONE and L. A. CLINTON (*New York Cornell Sta. Bul.* 182, pp. 368-385).—A report is given on culture, variety, and fertilizer experiments with sugar beets at the station, and of cooperative experiments along the same lines carried out by 38 farmers living in the vicinity of the two sugar-beet factories of the State. Data as to the character of the soil, varieties of beets grown, yield per acre in tons, percentage of sugar in beets, and purity of the juice are tabulated.

In the cooperative tests the variety Zehringen contained the highest average percentage of sugar in the juice, 16.47, and the highest percentage of purity, 81.8, of the 5 varieties tested, but gave the lowest average yield of beets, 11.1 tons per acre. The variety Mangold yielded the most sugar per acre, 3,662 lbs.

In the culture experiments at the station the time of thinning the beets seemed to have no effect whatever on the percentage of sugar in the juice of the beets or on the purity of the same.

The effects of fertilizing sugar beets with different forms of commercial fertilizers alone and combined on plats made exactly similar as regards soil conditions, are shown in tabular form for the years 1897-1899, inclusive, and summarized for all 3 years.

"Where nitrate of soda was used alone as a fertilizer the percentage of sugar in the beets was very materially reduced, as was also the purity of the juice. The average percentage of sugar in the beets where nitrate of soda alone was used was 13.53, with the purity of the juice 81.6. The average of all plats where no nitrate of soda was used was 16.24 per cent of sugar in the beets, with a purity of juice of 86.63.

"Contrary to the popular belief, the beets upon the plat receiving muriate of potash alone as a fertilizer contained the highest percentage of sugar of any of the beets grown, and the purity of the juice compared well with that of all others. The percentage of sugar in the beets fertilized with muriate of potash alone was 17.02, with a purity of the juice of 85.94. The average percentage of sugar in the beets grown on all plats not receiving any muriate of potash was 15.82, with a purity of the juice of 86.04. It is usually considered that the sulphate of potash is superior to the muriate of potash as a fertilizer for sugar beets, but our experiments do not indicate that the sulphate is superior in any way to the muriate."

Bulk fermentation of Connecticut tobacco, M. L. FLOYD (*U. S. Dept. Agr., Division of Soils Circ.* 5, pp. 10).—Changes in "styles" in tobacco have made desirable changes in the character of the Connecticut Valley product to accord more nearly with the present market demands. The present circular gives the results of experiments car-

ried out in cooperation with the Connecticut State Station in fermenting Connecticut tobacco by the bulk method used in Florida (E. S. R., 11, p. 729), Sumatra, and Cuba. This method is considered superior to the case method (E. S. R., 11, p. 730) of fermentation usually followed in Connecticut, as it greatly shortens the period of fermentation, tends to give a better color and aroma, and to largely eliminate the element of chance in tobacco fermentation. Details as regards the method of handling and the temperature records obtained in the bulk fermentation of about 3,000 lbs. of all grades of good leaf and 1,900 lbs. of trash tobacco are reported.

With regard to the results obtained the author states that—

“The Connecticut tobacco is not supposed to have any desirable filler leaves for domestic cigars, but this year’s experience has shown that the short top leaves if properly fermented will make a fairly good filler and that it will even pay to pick out such heavy-bodied top leaves from what is commonly classed as trash and ferment them for filler goods. Some of these heavy-bodied leaves were thoroughly fermented with very good results.”

The expert opinions of a number of Connecticut and New York dealers as to the quality of the bulk-fermented tobacco were obtained.

“They pronounced the leaf perfectly sound in every respect, color very desirable, and even the whole leaf perfectly fermented and having the appearance of old tobacco, while the grain was perfectly developed and the style excellent. The burn was also good. . . . It was the general expression that more had been gotten out of the leaf than had ever before been obtained, and that the method would entirely supersede the present case method of fermentation.”

Some of the top leaves of the trash which had been heavily fermented were made into “booked fillers” and submitted to dealers and manufacturers. They estimated its value at prices ranging from 15 to 18 cts. per pound, and in one instance, from 30 to 40 cts. per pound. Thin, trashy leaves were valued at about 7 cts. per pound.

In conclusion the author states that the work “while thoroughly satisfactory so far as the present style of leaf is concerned, has demonstrated that the Connecticut leaf needs to be radically changed to accord with the present market requirements.” Experiments with this end in view are being inaugurated.

Experiments with Alinit on winter wheat, R. SALZER (*Deut. Landw. Presse*, 27 (1900), No. 13, pp. 133, 134).—This article gives the results of experiments with Alinit on winter wheat in different districts of Austria.

In a trial in Giuliomajor alluvial soil containing humus was used. The wheat was sown October 10, 1897, and the plats harvested July 15, 1898. The yield of the inoculated plat was 2,009 kg. per hectare; the uninoculated, 1,738 kg., a gain of 271 kg. per hectare with Alinit.

In Budovalla, on lowland not easily cultivated and that had been treated with stable manure after lying fallow, the inoculated plat pro-

duced 1,680 kg., the uninoculated 1,549 kg. per hectare; a gain of 131 kg. by the use of Alinit. In Csanad, on alluvial soil containing humus, the yield with Alinit was 1,542 kg. per hectare; without, 1,490 kg.; a gain of 52 kg. by inoculation. In the district of Vizesda, on sandy soil well treated with stable manure, the yield per hectare with Alinit was 2,207 kg.; without, 1,738 kg., giving a gain of 469 kg. by inoculation. Trials on sandy loam gave a yield with Alinit of 1,477 kg. per hectare; without, 1,450 kg.; a gain of 27 kg. by inoculation.

In all cases a gain in yield was obtained by the use of Alinit, and in every instance but two, in Csanad and again in Vizesda, the gains were made at a profit. The grain lodged but little on the inoculated plats, and was little affected by rust. These features are considered of considerable importance by the author and will be studied further.

Experience notes on plat experiments, B. D. HALSTED (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 19-27).—Difficulties to be met in securing accurate results in field experiments are noted and some suggestions given for overcoming them.

Cassava culture in Florida (*Tradesman*, 44 (1900), No. 2, p. 67).—A brief note calling attention to the importance of this industry in Florida.

Cassareep in Paraguay, J. N. RUFFIN (*U. S. Consular Rpts.*, 63 (1900), No. 236, pp. 12, 13).—The growing of cassava in Paraguay is discussed, and the composition of two samples called *Mandioca dulce* and *M. amarga* is reported.

The manuring of catch crops, J. LESLIE (*Agr. Gaz.* [London], 52 (1900), No. 1385, p. 36).—Experiments in which the profitable use of commercial fertilizers, especially superphosphate and kainit, for catch crops of trifolium and Italian rye grass, are reported.

The utility of the cowpea, A. M. SOULE (*Tennessee Sta. Rpt.* 1899, pp. 67-71, fig. 1).—The value of the cowpea as a green manure and forage crop is discussed and suggestions given regarding its culture and use as a green manure. A comparison of its food value with that of other forage crops is made.

Notes on grasses, J. R. FAIN (*Tennessee Sta. Rpt.* 1899, pp. 74, 75).—Suggestions regarding seeding for succession. Timothy is regarded as excellent for permanent pastures in Tennessee.

Observations on buffalo grass, C. E. BESSEY (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 105, 106).—Notes on the disappearance of this grass from the western plains, with a brief account of a cultural experiment.

Why grasses fail, A. M. SOULE (*Tennessee Sta. Rpt.* 1899, pp. 71-73, fig. 1).—Lack of a properly prepared seed bed and the use of insufficient or impure seed are given as reasons for the failure of many meadows. Suggestions regarding seeding are given, together with a list of forage plants best suited to different soils and the amount of seed to be employed in each case.

The hop: Its culture and curing, marketing and manufacture, H. MYRICK (*New York: Orange Judd Co.*, 1899, pp. 299, figs. 137).—"A practical handbook on the most approved methods in growing, harvesting, curing, and selling hops, and on the use and manufacture of hops." Chapters are given on the history and peculiarities of the industry; characteristics and composition of the hop plant and its fruit; climate and soils for hops; laying out hop yards; manuring, planting, tying, and cultivation; hop pests; harvesting the crop; kilns for curing hops; curing, baling, growing, sampling, and marketing hops; concentration in hop growing; expenses and profits in the industry, and hop statistics.

The work deals especially with the methods of hop growing in New York and the Pacific States. Methods and practices followed in England and Germany are also

considered in some detail. Not the least valuable feature of the work is a glossary of hop terms by N. F. Walter. A bibliography of 17 books on hops is appended.

Hop culture in California, D. FLINT (*U. S. Dept. Agr., Farmers' Bul. 115*, pp. 26, figs. 2).—This bulletin discusses the methods of hop culture followed in California, including systems of training, tying up the vines, harvesting, curing, baling, marketing, and the prices, wages, and expenses involved in hop growing in that State. Some introductory remarks on the botanical features of the hop plant, varieties of hops grown in this country, counties in California devoted to hop culture, and the climatic conditions of California are given. Some hop statistics prepared by the Division of Statistics of this Department as to the acreage, yield, and value of hops in the United States in 1889 and 1890 conclude the bulletin.

Our mustards and their rôle in agriculture, A. BAROT (*Nos moutardes et leur rôle en agriculture. Paris: Charles Mendel*, pp. 63).

Tests of Alinit in the culture of oats and barley, A. DAMSEAUX (*Bul. Agr. [Brussels]*, 15 (1899), No. 7, pp. 615, 616).—Oats were not benefited by the use of Alinit. Barley gave increased yields of both grain and straw seemingly due to its action.

Oil-producing plants and their culture, V. KRIES (*Deut. Landw. Presse*, 27 (1900), No. 63, pp. 784, 785).—The various sorts of rape are dealt with especially.

Potato raising in Canada, W. T. MACOUN (*Amer. Gard.*, 21 (1900), No. 298, pp. 597-599).—The author states that the average yield of potatoes in Ontario is 115 bu. per acre. The average yield of 15 varieties at the Central Experimental Farm in 1898 was 240 bu. per acre. This difference in yield is thought to be largely due to more careful selection of seed and varieties by the station than is usually given by farmers. Of white-skinned varieties American Wonder, Empire State, and Carmen No. 1 are recommended, and of pink potatoes Everett and Rochester Rose. Early Ohio is considered a good potato for the early market. Seed, cultural methods, spraying, world's production of potatoes, etc., are other subjects discussed in the article.

Experiments on pasture (*Farm and Home*, 19 (1900), No. 963, p. 229).—Some details as to the effect of various manurial dressings are reported.

Experiments on pasture, 1900 (*Agr. Students' Gaz.*, n. ser., 10 (1900), No. 1, pp. 16-19).—Data on the hay yield of a large number of plats differently fertilized with commercial fertilizers and barnyard manure.

Manurial experiments in Devon (*Farm and Home*, 19 (1900), No. 963, p. 228).—A summarized report of results obtained by the Devon County Technical Education Committee in manurial experiments with root crops, potatoes, and grass.

Breeding experiments with rye and wheat, M. FISCHER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 16, pp. 609-613; 17, pp. 642-649, figs. 4).—The interrelation of quality and color of the grain was studied.

Three years' fertilizer experiments with rye on light soil (*Deut. Landw. Presse*, 27 (1900), No. 69, p. 861).—Plat experiments were made and 19 combinations of fertilizers used. The results are tabulated. The greatest profit followed the use of a mixture of 448 lbs. of kainit, 336 lbs. of Thomas slag, and 112 lbs. of nitrate of soda.

When do swedes cease growing? (*Farmers' Gaz.*, 59 (1900), No. 26, p. 509).—A record of measurements which show that in this test no root growth took place after November 1, though there was some leaf development.

Sugar beet analyses, A. E. SHUTTLEWORTH (*Ontario Agr. Col. and Expt. Farm Rpt. 1899*, pp. 48-50).—Analyses are given of a number of samples of sugar beets pulled at different dates between October 24 and November 27. The sugar in the beets ranged from 11.9 to 15.3 per cent with a purity coefficient varying from 74.1 to 82.5. The November-pulled beets were richest in sugar.

Improvement of sugar cane by chemical selection (*Florida Agr.*, 27 (1900),

No. 33, pp. 495, 496).—Text of a paper read by Professor Albuquerque before the West Indian Sugar Conference, held at Barbados, on the practicability of increasing the sugar content of cane by planting seed selected from canes which are shown by chemical analysis to be especially rich in sugar.

Sugar cane culture in Ecuador (*Mitt. Deut. Landw. Gesell.*, 15 (1900), *Sup.* to No. 26, pp. 209–215).—Cultural methods, methods and cost of manufacture, exports, and the possibilities of the sugar industry in Ecuador are considered in detail.

Tobacco (*Sci. Amer. Sup.*, 49 (1900), No. 1268, pp. 20332, 20333).—Some general notes on the culture and manufacture of tobacco in this and foreign countries.

Tobacco (*Bul. Bot. Dept. Trinidad* (1900), No. 24, pp. 252, 253).—Tobacco in Trinidad gives the best results when seeded in September, planted out in November, harvested in February, and dried and cured by the methods followed in Cuba a month later. A crop in 1899–1900 yielded at the rate of 800 lbs. of tobacco per acre, estimated to be worth 12 cts. per pound. The largest item of expense was in picking the worms night and morning.

Field fertilizer experiments on tobacco, W. FREAR (*Pennsylvania Sta. Bul.* 49, pp. 1–8).—The data here recorded have been abstracted from another source (*E. S. R.*, 11, p. 924).

Comparative analyses of tobacco, J. C. BRÜNNICH (*Queensland Agr. Jour.*, 7 (1900), No. 2, pp. 162, 163).—Complete analyses as regards acids, gums, alkaloids, oil, starch, resins, albuminoids, pectose bodies, and ash constituents are given in parallel columns of Virginia and Queensland raw leaf tobacco.

Results obtained from the cross-fertilizing of cereals, W. SAUNDERS (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 74–81). Changes in the composition of wheat effected by climate, soil, etc., are mentioned. Some Russian, Indian, and other varieties of wheat used in crossing are noted, and descriptions given of 5 crossbred wheats originated by the author and 2 hybrid barleys.

Report on experiments carried out at the experimental plats at Drakesbrook, G. BERTHOUD (*Jour. Dept. Agr. West. Australia*, 1900, May, pp. 56–76).—Notes on the manuring and growth of a number of varieties of wheat on new lands, old lowlands, and on highlands; and on fertilizer and variety tests with potatoes.

Wheat manuring experiments in Victoria, A. N. PEARSON (*Jour. Agr. and Ind. South Australia*, 3 (1900), No. 8, pp. 653–655).—The average results are given of growing wheat with concentrated superphosphates alone and combined with nitrate of soda. In one experiment Thomas slag was used, and in another, sulphate of ammonia. The experiments were carried out in 5 different localities under very unfavorable weather conditions. The increased yields obtained due to the fertilizers varied from 1 to 5.33 bu. per acre. The use of 10 lbs. of concentrated superphosphate per acre was scarce sufficient, while the use of 30 lbs. generally proved superabundant. The medium dressing of 20 lbs. gave the best average results. The use of nitrogen seemed to decrease the effect of the superphosphate.

Thick and thin seedings, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, II, No. 33, pp. 221, 222).—Experiments carried out at Princes Park in seeding wheat and oats at different rates are reported. Wheat was drilled at rates of 90, 156, and 194 kg. per hectare, and oats at rates of 36, 105, and 162 kg. per hectare. With both crops the yields increased as the quantity of seed sown increased. In a test of sowing similar amounts of seed broadcast and in drills, seeding in drills gave largely increased yields over the broadcasted plats with both oats and wheat.

Deep-rooted plants as related to the health of crops, J. KLÖCKER (*Deut. Landw. Presse*, 27 (1900), No. 49, pp. 631, 632).—A compiled article showing the greatly increased length and development of potato roots when preceded by a crop of long-rooted lupines, and the consequent increase in growth of vines, freedom of the vines from disease, and yield of tubers. These results were especially noticeable in dry years, and are thought to be due to the greater supply of water brought within

reach of the plants by the longer roots, which resulted in a vigorous growth. Deep working of the soil produced similar results.

Accessories in grain breeding, VON SEELHORST (*Deut. Landw. Presse*, 27 (1900), No. 43, pp. 533, 534, figs. 3).—Devices to facilitate work in grain breeding and improvement are described, illustrations being given in some instances.

The value of seed selection, C. R. GIES (*Farming World*, 18 (1900), No. 3, p. 117).—The increased yields obtained by the author by using large plump seed rather than small plump seed are tabulated for oats, barley, wheat, and peas. With average crops on a farm of 100 acres the increased value of the crop due to seed selection is calculated at \$217 yearly.

HORTICULTURE.

Experiments to determine the amount of water used by crops, H. VON SCHRENCK and H. C. IRISH (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 96, 97).—Pot and bench experiments in a greenhouse were made with radishes, cauliflowers, tomatoes, and beans. The maximum amount of water was required by the radishes during the third week's growth. With cauliflowers the maximum was reached after 10 weeks, and with beans and tomatoes after about 6 weeks.

In one experiment the fruit or heads of tomatoes, beans, and cauliflowers were removed as soon as formed in one series, while in the other they were allowed to mature. "The plants in the first series, on an average, had the period of maximum amount of water transpired at a later date than those of the second series." The amount of water transpired for each gram of dry substance formed by these vegetables was as follows: Radishes, 539 gm.; beans, 384 gm.; and cauliflowers, 324 gm.

Notes on vegetables, J. CRAIG (*Iowa Sta. Bul.* 47, pp. 308-337, figs. 18).—These notes are made up largely of results of variety tests with cucumbers, eggplants, peppers, Lima beans, sweet potatoes, and tomatoes. Cultural directions are given in each instance, together with the methods employed in combating injurious insects and diseases. Four recipes are given for preparing eggplant for the table.

The most satisfactory varieties of the different crops grown are as follows:

Cucumbers: *Early*—Boston Pickling, Evergreen, Green Cluster; *mid-season*—Cool and Crisp, Taily Hybrid, White Spine, and Commercial Pickle; *late*—Long Green, Short Green, and Giant Pera. Eggplants: Fordhook Improved, New York Improved, White Improved, and Round Purple. Peppers: Red Chili, Ruby King, Golden Dawn, and Long Cayenne. Lima beans: Carolina, Jersey Extra Early, Horticultural Lima. Descriptive notes on 18 varieties are added. Sweet potatoes: Florida, Red Jersey, Benson, and Early Carolina. Descriptive notes on 12 varieties are added. Tomatoes: *Early mid-season varieties*—Early Ruby, Perfection, and Ignatum; *late varieties*—Buckeye State, Best of All, Favorite, and Fordhook First.

In a test of methods of training tomato vines 2 vines each of 6 varieties were (1) allowed to grow naturally, (2) trained to a 4 foot stake,

(3) hilled and a good-sized mound of earth drawn up at the base of the plants when fruit began to set, and (4) mulched, 4 in. of strawy manure being spread under the vines as the fruit began to set. The yields of good and of rotten fruits obtained from the different varieties by each method of training are detailed. The following table summarizes these data:

Results of training tomatoes.

Vines, how treated.	Yield, sound fruit.	Yield, rot- ten fruit.	Ratio, rotten fruit.
	Lbs. ozs.	Lbs. ozs.	Per cent.
Untrained.....	157 14	34 7	20.0
Staked.....	197 5	15 7	7.9
Hilled.....	184 10	20 10	10.8
Mulched.....	253 14	44 4	17.5

"This summary shows that the smallest yield was given by the untrained vines and that the percentage of rotten fruit on these was greater than in any other case; that staked vines gave a larger percentage of sound fruit than untrained and showed the smallest percentage of decayed fruit in the experiment; hilling did not give any striking results; mulching greatly increased the productiveness and also the tendency to rot. These are the results obtained during a year of unusually large precipitation in June and marked by light rainfall in August and September."

The solidity of the flesh of 13 varieties was determined by their specific gravity.

"According to this test Terra Cotta takes first place of those tested, being equal in weight to an equal volume of water. This indicates small seed cavities and firm flesh. There is a difference of 26 gm. between Terra Cotta and New Jersey, meaning that New Jersey was 26 gm. lighter than the volume of water which it displaced and thereby suggesting large seed cavities. Large seed cavities, or lack of solidity, would seem to be correlated with susceptibility to rot, as New Jersey, a light tomatfo, rotted to the extent of 27 per cent, while Terra Cotta and Lorillard, both heavy varieties, were affected to the extent of only 5 and 14 per cent, respectively."

Experiments with muskmelons, F. W. RANE (*New Hampshire Sta. Bul.* 70, pp. 17-44, figs. 7).—In the author's study of muskmelons an examination was made of the pistillate flowers of 93 varieties grown under both field and forcing-house conditions. In 83 of these so-called pistillate flowers he found both stamens and pollen, and the pollen was effective in the production of fruit. From these results it would seem that the general belief that the muskmelon is monœcious needs qualification.

An experiment was conducted to determine the comparative yield and profitableness of sowing seeds out of doors and of transplanting plants started early. Three varieties were used in the test. The vines grown in the field from seed gave the best yields in every instance. The comparative earliness up to September 5 of the trans-

planted vines and of the vines grown from seed sown in the field is shown in the following table:

Comparative earliness of muskmelons transplanted or sown in the field.

Variety.	Yield of 10 hills.				Total yield to Sept. 5.	Gain from trans-planting.
	Aug. 23.	Sept. 1.	Sept. 2.	Sept. 5.		
Rose Gem:						
Transplanted	2	5	11	12	30	18
Seed			3	9	12	
Netted Gem:						
Transplanted			10	13	23	17
Seed			2	4	6	
True Jenny Lind:						
Transplanted		2	6	2	10	1
Seed			3	6	9	

“Whether this extra-early yield [from transplanting] will pay for the extra labor can be determined only by the conditions and facilities of the grower. Generally speaking, it is doubtless a questionable undertaking, but in a few instances might be profitable.” From September 5 on, the planted hills outyielded those which were transplanted.

In the experiment to determine the relative productiveness of pinched v. unpinched vines, pinching the main vines and allowing the laterals to grow naturally, or pinching the main vine when it was 3 ft. long and the laterals after two fruits had set on each, was found to increase the yield scarcely at all, and if the work of pinching be taken into consideration, the practice resulted in a loss. The practice of pinching or heading-in is not considered desirable when vines are grown out of doors.

Removing the staminate blossoms, which usually appear some time before the pistillate flowers, increased the yield slightly, but the additional labor required rendered the practice unprofitable.

Variety tests of muskmelons at the station have been previously noted (E. S. R., 10, p. 50). Illustrations and descriptions of varieties not previously noted are here included, together with tabular data on the yields, dates of ripening and flowering, and form characteristics of 95 varieties. Out of a list of about 100 recently imported varieties, the variety Lida, of Russian origin, was the only one which gave satisfactory results. The following list of best varieties is recommended for planting in the North: *Gem type*—Oval Netted Gem, Golden Netted Gem, Netted Gem, Rose Gem, Paul Rose, and Emerald Gem. *Medium type*—Extra Early Hackensack, Kinsman Queen, Satisfaction, Chicago Nutmeg, Improved Jenny, New White Japan, Nectar of Angels, Extra Early Cantaloupe, and Acme. *Large, long type*—Granite State, Long Yellow, and Improved Cantaloupe.

Onion growing, F. A. HUNTLEY (*Idaho Sta. Bul. 22*, pp. 115-127, figs. 8).—Methods of onion culture adapted to Idaho soils and climate

and based on three years' experience in growing onions at the station are given. Six varieties are described, and the comparative results obtained in growing the greater number of these by transplanting and from seed sown in the open field are shown in tabular form. The transplanted bulbs gave the best results in every instance. Prizetaker stood at the head of the varieties tested, whether transplanted or grown from seed in the open field. The labor involved in the two methods of onion culture are considered to be about the same. Directions for irrigating onions are given.

The Oregon prune: Its composition, food value, soil draft, G. W. SHAW (*Oregon Sta. Bul. 61, pp. 18*).—This bulletin presents the results of analyses of a large number of samples of fresh and cured Oregon prunes. Previous work of a similar character at the station (E. S. R., 9, p. 753) is reviewed. The results, showing the proportion of flesh, juice, and pits, and the composition, are tabulated and summarized. Some of these data follow.

Composition of prunes.

	Average weight.	Percentage of flesh.	Percentage of juice in flesh.	Water.	Protein.	Nitrogen-free extract (including fat and fiber).	Sugar.	Acid.	Ash.
	Gm.			Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.
Oregon fresh prunes (average)	29.3	94.5	81.7	77.37	1.14	21.14	2.39	0.35	0.83
Oregon fresh prunes (Petites)	22.2	94.28	78.6	72.26	1.14	25.49	13.14	.35	.76
Oregon fresh prunes (Italians)	29.8	94.39	76.4	77.07	1.09	20.56	10.82	.42	.86
Oregon dried prunes (average)	19.27	2.03	76.48	2.22
California prunes (average)	80.20	.80	18.5040	.50
California plums	78.40	1.00	20.1040	.50
Oregon cherries	81.30	.90	17.3050
California cherries	79.40	1.20	19.0040

With reference to cured prunes the author states that—

"The average of all analyses shows [Oregon] prunes to contain about seven times as much edible matter as waste (pits). The fruit which had satisfactory keeping qualities carried about 20 per cent of water. From the observations made I do not regard it as safe to leave a greater quantity of water than this in the fruit. In most cases where the fruit carried over this there was a tendency toward mold. . . . The fact that this product carries about 80 per cent of dry matter shows that it is of high food value. About three-eighths of this is composed of the carbohydrates which serve to develop energy and fat, hence prunes must be considered as essentially a fattening food and should be used with other foods rich in nitrogen."

The average results of ash analyses of prunes are given, and are discussed with reference to the draft on the soil. A fertilizer consisting of 2,000 lbs. of air-slaked lime and 400 lbs. of muriate of potash is suggested for prunes on Oregon soils.

The resistance to drought of some American vines, C. GRIMALDO (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 25, pp. 731-734*).—The relative resistance to drought of some 70 hybrids and varieties of grapes grown in both sandy and clay soils is shown in tabular form.

In general, American varieties leave much to be desired as regards their resistance to drought. European-American hybrids proved more resistant than American sorts. Some varieties of *Riparia* proved quite satisfactory. *Rupestris* suffered, especially in sandy soils. *Berlandieri* of the American species proved most resistant to dryness, and this quality was often found in its hybrids.

A new substitute for rubber (*Sci. Amer.*, 82 (1900), No. 20, pp. 309, 310).—It is reported that a substitute for rubber has been found in the extract obtained by hydrocarbon solvents from the macerated wood of a shrub growing in Central Mexico, sometimes called yule, and having the botanical name of "*Synathereæas mexicanas*."

"The shrub grows wild on the rolling land and attains the average height of 3 ft. . . . It grows abundantly, may be easily cultivated, roots readily from cuttings, may be cut two or three times a year and immediately begins to grow, and shoots up again to form new wood. It does not belong to the plants which yield milky juices, being a comparatively hard wood and growing as a small scrubby bush, but there is found within its bark and wood a large amount of gummy matter, and upon comminuting it by cutting finely, grinding, or pounding the same, and macerating it with a hydrocarbon solvent, such as gasoline, naphtha, ether of petroleum, oil of turpentine, or the like, this gum is softened and extracted from the wood, and when extracted does not harden to crystallization, but still holding a small portion of the hydrocarbon remains as a viscid sticky mass that fulfills all of the physical conditions of crude rubber. It may be vulcanized perfectly, and is superior to most India rubber, since it is free from all mechanical impurities, and needs no preliminary cracking, grinding, and washing as does the ordinary crude rubber."

The process of maceration is described. A yield of 40 lbs. of gum, having a density at 15° C. of 0.98, is reported for each 100 lbs. of the shrub macerated. Its advantages over ordinary rubber are saving in cost of reproducing the plant, exportation, material used in purifying establishments, fuel, machinery, and time.

Plant breeding, D. R. PILLSBRY (*Florida Agr.*, 27 (1900), No. 38, pp. 561, 562).—Popular presentation of some results already obtained by plant breeding.

Summary of the work of the horticultural division for the year 1899, S. T. MAYNARD (*Massachusetts Hatch Sta. Bul.* 66, p. 19).—Summarized results obtained in variety and fertilizer tests with orchard and small fruits and grapes are reported and suggestions given on thinning fruits and the pruning of fruit trees and plants. A spraying calendar concludes the bulletin. In the fertilizer tests with apples on sod, marked improvement was observed only when nitrate of soda was used.

Report of the assistant in horticulture, A. T. JORDAN (*New Jersey Stas. Rpt.* 1899, pp. 131-187, pl. 1, dgm. 1).—The fertilizer and irrigation work here reported in detail with blackberries, raspberries, strawberries, currants, gooseberries, orchard fruits, lettuce, and tomatoes is in continuation of similar work reported in 1898 (*E. S. R.*, 11, p. 735), and has been abstracted from another source (*E. S. R.*, 11, p. 1039). Articles included in these pages on pear growing in New Jersey and on forcing tomatoes have also been noted (*E. S. R.*, 12, pp. 144, 146). In experiments with lettuce, radishes were grown between the rows and subject to the same conditions of soil, irrigation, and fertilizers. With this crop, surface irrigation proved better than subirrigation, and benches seem to have given better results than solid beds. Lime added to a good forcing soil resulted in considerably decreasing the yield of radishes, while nitrate of soda on the same soil in the absence of mineral fertilizers decidedly increased the yield.

Report of the horticulturist, H. L. HUTT (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 87-92*).—This report covers the results obtained in tests with orchard fruits, small fruits, grapes, ornamental plants, and tomatoes. Of the grapes tested, Moore Diamond, Worden, Early Ohio, Wyoming Red, Moore Early, and Jessica were the hardiest varieties grown. Earliest of All, Atlantic Prize, Stone, and Aristocrat were the most satisfactory tomatoes grown.

The best cantaloup for the Paris market, L. MESLÉ (*Rev. Hort., 72 (1900), No. 16, pp. 464-466, figs. 3*).—Different forms of the Large Prescott variety are noted and the qualities sought by the trade in cantaloupes pointed out.

Lettuce culture under canvas, H. G. FLETCHER (*Florida Agr., 27 (1900), No. 35, p. 520*).—A popular presentation of cultural details involved.

Onions, R. H. GARRAHAN (*Tennessee Sta. Rpt. 1899, pp. 64-66*).—Popular cultural directions for growing onions and onion sets.

New Zealand spinach as a garden crop, H. C. IRISH (*Proc. Soc. Prom. Agr. Sci. 1899, pp. 30-34*).—The nature of this plant, known also as New Zealand iceplant (*Tetragonia expansa*), its use for greens, and methods of culture are discussed. The seeds are slow of germination, requiring from 3 to 4 weeks' time, and seeds more than a year old require from 3 to 4 times as long for germination. Soaking the seed in warm or boiling water for various lengths of time had but little influence in hastening the period of germination. Each plant will furnish about a peck of greens a week and continue to furnish a supply until heavy frosts.

Tomato products, E. BONAVIA (*Sci. Amer. Sup., 49 (1900), No. 1268, p. 20333*).—The uses of fresh tomatoes; Italian tomato preserves; tomato chutney—a kind of relish for curries, cold meat, and fish; tomato sauce; and green tomato jam are noted, recipes being given for making.

The cultivation of yams (*Queensland Agr. Jour., 7 (1900), No. 1, pp. 58-60*).—Several species of tropical yams (*Dioscora* spp.) are described and cultural directions given.

Orchard management, J. C. BLAIR (*Illinois Sta. Bul. 59, pp. 371-396, figs. 9*).—Popular directions for the cultivation, pruning, fertilizing, and spraying of orchards, with notes on fungicides and spraying machinery. The bulletin is written with special reference to Illinois conditions.

The renovation of unproductive orchards. Why are old orchards unproductive? C. A. KEFFER (*Tennessee Sta. Rpt. 1899, pp. 57-61, fig. 1*).—Popular discussion of this subject, with suggestions regarding the time, method, and purpose of pruning.

Fertilizers for the orchard, C. A. MOOERS (*Tennessee Sta. Rpt. 1899, pp. 61-64*).—The necessity for orchard fertilization is pointed out, and the principles involved in the use of nitrogen, potash, and phosphoric acid in the orchard are noted.

The manuring of fruit trees, R. BRUNET (*Jour. Agr. Prat., 1900, II, No. 34, pp. 277-280*).—A general discussion of the principles involved.

Irrigation in fruit growing, E. J. WICKSON (*U. S. Dept. Agr., Farmers' Bul. 116, pp. 48, figs. 8*).—A popular discussion of the relation of irrigation to fruit production and of irrigation methods. The work is based on Pacific Coast experiences and deals with all the more important phases of diverting, pumping, storing, and applying water to orchard fruits when grown on different soils and under different climatic conditions.

Observations on packing and transport of plants, fruits, and seeds, J. H. HAET (*West Indian Bul., 1 (1900), No. 3, pp. 296-305, figs. 3*).—Diagrams and descriptions are given of 3 different forms of packing cases for plants. Fruit and seed packing and shipping are also considered.

Storing apples for exposition (*Amer. Gard., 21 (1900), No. 290, p. 470*).—This article has been abstracted from another source (*E. S. R., 11, p. 849*).

Notes on figs under glass (*Jour. Hort.*, 52 (1900), No. 2710, p. 220).—Cultural and fertilizer notes.

Mangoes (*Bul. Bot. Dept. Trinidad*, 1900, No. 24, pp. 257-271, figs. 7).—Seven promising sorts of mangoes growing in the botanical gardens are illustrated in outline and described.

Pineapple culture, T. COOMBER (*Garden*, 58 (1900), No. 1496, p. 48).—Directions for the culture of this fruit under glass.

Fertilizers for pineapples (*Bul. Bot. Dept. Jamaica*, n. ser., 7 (1900), No. 3-5, pp. 39-45).—In experiments with different fertilizers in Jamaica the use of 550 lbs. of cotton-seed meal supplemented with 100 lbs. of high-grade sulphate of potash at time of flowering has given the best results. The use of phosphoric acid for pineapples has been without any effect whatever. A review is given of Rolfs' experiments in fertilizing pineapples in Florida (*E. S. R.*, 11, p. 739).

Protection of small fruits from frost, J. W. SMITH (*Jour. Columbus Hort. Soc.*, 15 (1900), No. 2, pp. 89-91).—The use of various coverings, smudges, etc., for protection against frosts are considered.

Notes on varieties of the strawberry, W. R. LAZENBY (*Jour. Columbus Hort. Soc.*, 15 (1900), No. 2, pp. 94-97).—The characters which an ideal strawberry should possess are noted and an account given of the growth of 11 of the newer varieties fruited on the Ohio State University grounds in 1900.

Strawberries in Ohio, M. CRAWFORD (*Amer. Gard.*, 21 (1900), No. 300, pp. 629-631).—As the result of tests the author concludes that "those who want the largest, best, and most beautiful berries should grow the Marshall for early, Gandy or Empress for late, and the Wm. Belt, Downing Bride, Sample, Nick Ohmer, and Margaret. Those who want 'good berries and lots of them' should grow August Luther or Johnson Early for early, Klondike or Hunn for late, and Senator Dunlop, Wm. Belt, Sample, McKinley, Warfield, and Ridgeway." For big berries for market the additional list of Clyde, Bubach, Haverland, Parker Earle, and Parsons Beauty are recommended.

Grape growing in the South, S. M. TRACY (*U. S. Dept. Agr., Farmers' Bul.* 118, pp. 32, figs. 6).—Under this heading the author discusses the location of the vineyard, methods of propagation, selection of varieties, planting, cultivating, fertilizing, pruning, training, and gathering the fruit. Notes are also given on the insects and diseases of grapes and suggestions as to methods for their control.

Green manures in vineyards, A. CARRÉ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21, (1900), No. 11, pp. 322-327).—The value of the practice and of different plants for the purpose are considered.

Grafting resistant vines, F. T. BIOLETTI (*Pacific Rural Press*, 60 (1900), No. 4, p. 52).—A controversial article in which the superiority of grafting in the field over bench grafting resistant vines is questioned. "While this superiority may be real with regard to Lenoir and other similar stocks, it is doubtful with regard to Riparia varieties, and almost certainly not true with respect to all Rupestris varieties."

The irrigation of vineyards, P. FERROUILLAT (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 18, pp. 524-531).—This article is largely devoted to a discussion of the size of the ditches, tiles, and wells needed in irrigating vineyards.

Caoutchouc or India rubber: Its origin, collection, and preparation for the market, etc., J. C. WILLIS (*Roy. Bot. Gard. Ceylon Circ.*, 1. ser., 1899, No. 12-14, pp. 105-168, figs. 4).—The results of a number of experiments in tapping, collecting the latex, and preparing the rubber for the market are included in the circular.

Commercial culture of caoutchouc, F. HERBET (*Manuel de culture pratique et commerciale du caoutchouc*. Paris: J. Fréchet, 1899, pp. 138, figs. 38).

Caoutchouc-producing plants, P. VAN ROMBURGH (*Teyssmannia*, 11 (1900), No. 1, pp. 16-24).—*Willughbeia firma*, belonging to the Asclepiadaceæ, is common in the East Indies and produces an abundance of caoutchouc of fair quality. It is a climber

with short-stalked leathery leaves and small white flowers. A vine $6\frac{1}{2}$ years old may be expected to yield 100 gm. of marketable caoutchouc.

Willughbeia tenuifolia is common with the former species and produces a gutta-percha of inferior quality.

The product of *Willughbeia firma* is not equal to that of *Ficus elastica* but a greater quantity is produced by crushing the sections of stem after the flow of sap has ceased. Special factories have been built to crush the stems and prepare the product for market.—H. M. PIETERS.

About vanilla (*Boston: Joseph Burnett Co., 1900, pp. 44, figs. 9*).—Popular account of the habitat, history, culture, and curing of the orchid producing the vanilla bean.

Experiments with lawn grasses, B. D. HALSTED (*New Jersey Stas. Rpt. 1899, pp. 409, 410*).—A report is given of 9 plats of grass which were seeded in 1896, in which 9 different species of grass are compared for lawn purposes. Notes are given upon the relative value of each. Based upon the experiments of 4 years, the author suggests as a satisfactory lawn mixture Rhode Island bent grass, Kentucky blue grass, redtop, and perennial rye grass.

American floriculture, retrospective and prospective, B. T. GALLOWAY (*Florists' Exchange, 12 (1900), No. 36, pp. 868, 869*).—Historical and statistical review.

Ornamental trees and shrubs, W. R. LAZENBY (*Jour. Columbus Hort. Soc., 15 (1900), No. 2, pp. 63-68*).—Paper read before the society at its April meeting. It discusses the planting of trees and shrubs for home grounds, public grounds, and roadsides.

Ornamental climbers, W. R. LAZENBY (*Jour. Columbus Hort. Soc., 15 (1900), No. 2, pp. 85-88*).—A number of annuals and perennials are noted, their characters being given.

Status of the rose, E. G. HILL (*Amer. Gard., 21 (1900), No. 297, pp. 583, 584*).—The author holds that in order for the rose to hold the same high place in American gardens that it does in English and continental gardens it must first be freed from the fungus disease known as the "black spot." If this can not be done a new race of roses must be built up by crossing the hardier species with our present highly developed Tea and Hybrid Tea varieties. For forcing purposes varieties with new colors are needed—something "like Gen. Jacqueminot, or Rodocanachi, or a variety with the tint and fragrance of Marechal Niel combined with the fine practical qualities of Bride or Bridesmaid."

The best sweet peas (*Amer. Gard., 21 (1900), No. 299, p. 612*).—Some of the most popular exhibition varieties of sweet peas at the recent Sweet Pea Conference in London in the decreasing order of merit were: Blanche Burpee, Mars, Lovely, Navy Blue, Triumph, Mrs. Eckford, Princess of Wales, Queen Victoria, Lady Grisel Hamilton, America, Black Knight, Salopian, and Sadie Burpee. A list is given showing the merits of each variety in the entire competitive display.

The classification of sweet peas (*Amer. Florist, 16 (1900), No. 637, pp. 56, 57*).—A list is given of sorts adjudged the most distinct and also of those which have received awards from the Royal Horticultural Society.

SEEDS—WEEDS.

The germination of seeds as affected by certain chemical fertilizers, G. H. HICKS (*U. S. Dept. Agr., Division of Botany Bul. 24, pp. 15, pls. 2*).—A series of investigations are reported, in which the effect of immediate application of certain chemical fertilizers to seeds is shown by the germination and growth of the seedlings.

Previous investigations in this line are reviewed and an outline of the author's experiments is given, in which it is claimed that ferti-

lizers are generally supposed to influence the swelling of the seed, the nature and availability of the reserve material, the awakening and growth of the embryo, and the young sprout before it reaches the surface of the soil. A large number of experiments were conducted with wheat, lettuce, radish, and crimson clover seed grown in soil in a greenhouse. The fertilizers used were nitrate of soda, muriate of potash, boneblack, oyster-shell lime, and a mixed fertilizer consisting of boneblack, muriate of potash, and nitrate of soda. These different substances were drilled in the rows in which the seeds were planted and also mixed with the soil. In the tabular results it is shown that in many cases, if not in most, the application of the fertilizer directly in the row had detrimental effects, and the injurious influence was exerted upon the sprout after it had passed through the seed coats. The author's summary of his results is as follows:

"(1) That muriate of potash and sodium nitrate used as fertilizers in strengths of 1 per cent or more are very detrimental to the germination of seeds, whether applied directly or mixed with the soil.

"(2) That fertilizers composed of phosphoric acid or lime are much less injurious to germination than sodium nitrate or muriate of potash, and if not used in excess may be harmless.

"(3) That commercial fertilizers should not be brought into direct contact with germinating seeds.

"(4) The effect of treating seeds with chemicals before planting is no index to the action of those chemicals when applied as manure to the soil.

"(5) That the chief injury to germination from chemical fertilizers is inflicted upon the young sprouts after they leave the seed coat and before they emerge from the soil, while the seeds themselves are injured only slightly or not at all.

"(6) It is highly improbable that potash, phosphoric acid, nitrogen, or lime used as fertilizers actually favor germination."

Investigations on the rôle of oxygen in germination, P. MAZÉ (*Ann. Inst. Pasteur*, 14 (1900), No. 5, pp. 350-368).—The author has investigated the effect of submersion on the germinative power of seed and also the diastatic action produced by such treatment. Peas, maize, lupines, peanuts, colza, cabbage, lucern, and clover were studied.

The failure to germinate on the part of submerged seed was found to be due to a lack of aeration. The hydrolyzing enzymes, especially zymase, continued their activity, but the oxidizing diastases were unable to produce the liquefied condition necessary for the elaboration of the reserve material, and as a result the embryos remained dormant. In the case of small seeds, such as the crucifers, it was found that they were able to develop slowly, the air content of the seeds being sufficient to supply the oxygen necessary for respiration. Starchy seeds were found to lose their germinative ability sooner than oily ones when submerged, but there is nothing to indicate that any kind of seed can long endure such a state.

The actual diminution of vitality of seeds which have been submerged in water is said to be largely due to the production of poison-

ous compounds, particularly aldehyde, in the surrounding liquid. The temperature at which the experiments were carried on was found to have an important bearing on the results.

The destruction of weeds in cereal crops by means of solutions of chemicals sprayed upon the foliage, H. L. BOLLEY (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 107-109).—The author reports having made in 1896 attempts to destroy the English charlock by means of a solution of corrosive sublimate sprayed over oat fields. The strengths of solutions selected and the weather conditions were such that the experiment was a failure.

In 1899 the author conducted a series of experiments for the destruction of weeds over large areas by spraying the crops with different solutions and in the present paper he reports upon the effect of copper sulphate as a weed destroyer. The effect of a 10 per cent solution of copper sulphate sprayed over wheat is stated. At the time of the spraying, the wheat was 3 to 5 in. in height and the portion of the field selected for the experiment was exceedingly weedy, the principal weeds being charlock, wild barley, wild rose, penny cress, shepherd's purse, wild buckwheat, lamb's quarter, and the great ragweed. This application was made June 1 and on August 8 all the weeds except the wild rose and older plants of penny cress had been destroyed. The wheat leaves were burned slightly at the tip, but the yield was considerably larger than that of an adjoining untreated plat. A number of tests were made with a 1 per cent solution of copper sulphate which was found to kill the great ragweed and charlock but failed to destroy the older plants of penny cress. June 20 an oat and mustard field was sprayed with copper sulphate at the rate of 1 lb. to 4 gal. of water. The oat plants were about 6 in. high, the mustard about equaling it or in some places a little higher. On August 1 the crop on the treated area was entirely free from weeds except for pigeon grass and wild rose. The plants were stalky and well stooled. Upon the untreated area the plants were weak and failed to stool, and the crop was considered at least $\frac{1}{3}$ less than upon the treated plat. The amount of liquid used in the author's experiments was approximately 40 gal. per acre, and he believes the results indicate that spraying to destroy weeds in cereal crops can be carried out on an economic basis.

Seed selection, P. O. VANATTER (*Tennessee Sta. Rpt.* 1899, pp. 75, 76, fig. 1).—Popular notes are given on the advantages derived from the use of clean seed and also the value of selected seed in the improvement of crops.

Clover seed, A. D. SELBY (*Ohio Sta. Spec. Bul.* 4, pp. 7, figs. 31).—Notes are given on the vitality, purity, and manner of testing clover seed. A number of the more common weed seeds found in samples of clover seed are figured by means of photo-engravings. Detailed reports are given on the analyses of 15 samples of clover seed purchased in the market, and comparisons are drawn between the market price and the actual value of the seed.

Some methods of seed investigation, L. VON THAISZ (*Bot. Centbl.*, 82 (1900), No. 9, pp. 269, 270).—Different methods for treating refractory seed before placing them in the germinating chamber are discussed. For such seeds the author recommends soaking in water, after which they are heated in weak caustic potash and then neutralized with acetic acid.

Regulations and standards of the Vienna seed-control station, T. RITTER VON WEINZIERL (*Pub. K. K. Samen-Control-Sta. Wien*, No. 208, pp. 23).

Rules for agricultural wholesale dealers of seeds and feeding stuffs, T. RITTER VON WEINZIERL (*Pub. K. K. Samen-Control-Sta. Wien*, No. 205, pp. 23).

Composition of grass-seed mixtures, T. RITTER VON WEINZIERL (*Pub. K. K. Samen-Control-Sta. Wien*, No. 207, pp. 48).—A third edition of the author's bulletin on grass-seed mixtures. Suggestions are given for making grass mixtures for different purposes and the amount of seed required per hectare.

Some difficult germinations, N. BERNARD (*Rev. Gén. Bot.*, 12 (1900), No. 135, pp. 108-120).—Results are given of a study of the germination of a number of seeds and spores of plants whose subterranean parts are normally inhabited by endophytic fungi. The plants studied were several species of orchids, lycopodiums, and ferns.

Resistance of seeds to mercury, C. DE CANDOLLE (*Arch. Sci. Phys. et Nat.*, 8 (1899), pp. 517, 518; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 2, p. 222).—Grains of wheat, after being submerged for 4 years in mercury, were germinated and produced normal plants.

Nineteenth annual report of the Vienna seed-control station, T. RITTER VON WEINZIERL (*Jahresber. K. K. Samen-Control-Sta. Wien*, 1900, pp. 32).—Gives a report of the activity of the station for the year ended July 31, 1899. During this period 25,763 analyses were made, as well as field and laboratory investigations upon a number of topics, as grass mixtures; experiments with Nitragin and Alinit; and studies of clover, beet, flax, tree, and cereal seeds. The usual data as to purity, germinative ability, etc., are given in tabular form.

The vitality of weed seeds twenty years in the soil, W. J. BEAL (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 86, 87).—This article has been previously noted (E. S. R., 11, p. 856).

New weed arrivals, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 37-39, figs. 3).—Descriptive notes are given of 2 weeds which have made their appearance in Ontario, and it is thought possible may become troublesome. They are prickly lettuce (*Lactuca scariola*) and the broad-leaved gum plant (*Grindelia squarrosa*).

Experiments with weeds, B. D. HALSTED (*New Jersey Stas. Rpt.* 1899, pp. 407, 408).—In continuation of experiments outlined in a previous report (E. S. R., 11, p. 749), the author has conducted his investigations on the ability of weeds to withstand or encroach upon each other. These experiments have been conducted for 3 seasons. The most aggressive weeds at the present time are *Ambrosia artemisiifolia*, *Polygonum persicaria*, *Syntherisma [Panicum] sanguinalis*, *Rumex acetosella*, and *Alsine media*.

The extermination of weeds, E. W. HILGARD (*California Sta. Circ.*, Sept., 1898, pp. 3).—Brief rules are given regarding the principles of weed extermination.

The passing of the Russian thistle, C. E. BESSEY (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 83-85).—This paper has been previously noted (E. S. R., 11, p. 858).

Destruction of Cardamine pratensis, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, I, No. 21, pp. 742, 743).—Notes the destruction of this weed by spraying with copper sulphate. The author advised the substitution of iron sulphate for copper sulphate on account of the possible injury to stock eating herbage that contained considerable of the copper. Analyses of samples of mixed herbage that had been sprayed with copper sulphate showed about 3.94 gm. of copper sulphate to 10 kg. of forage.

The destruction of troublesome cruciferous plants, A. VILCOQ (*Jour. Soc. Agr. Brabant-Hainaut*, 1899, pp. 718, 719).

Destruction of charlock by spraying with solutions of iron and copper sulphate, C. JOURNÉE (*Agronome*, 1899, pp. 435, 436).

The destruction of thistles and charlock by ammonium sulphate, G. CASTEL-DELÉTREZ (*Jour. Roy. Soc. Agr. L'Est Belg.*, 1899, p. 199).

Charlock spraying (*Ann. Rpt. Field Expts. Irish Agr. Organization Soc.*, 1 (1899), pp. 43-46).—Results of spraying experiments with iron and copper sulphate solutions for the destruction of charlock in barley fields are given. A solution of copper sulphate, 3 or 4 per cent, at the rate of 40 gal. per acre gave the best results. Stronger solutions injured the barley to some extent. Dock and thistles were injured, but not killed by the spray.

Recent experiments in combating charlock, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, I, No. 15, pp. 525-527).—A 12.5 per cent solution of iron sulphate sprayed over weed-infested crops at the rate of about 200 liters per acre is said to destroy charlock, mustard, wall flower, and ground ivy, without injury to cereals, clovers, colza, and lupines.

Combating field mustard, T. RITTER VON WEINZIERL (*Pub. K. K. Samen-Control-Sta. Wien*, No. 199, pp. 1-3).—Recommends spraying fields with a 15 per cent solution of iron sulphate at the rate of 40 to 50 gal. per acre.

DISEASES OF PLANTS.

Report of the botanist, B. D. HALSTED (*New Jersey Stas. Rpt.* 1899, pp. 323-419, figs. 16).—The principal lines of experimentation reported upon are investigations on truck crops, of which turnips, potatoes, beans, tomatoes, and eggplants have been foremost. The soil treatments for club-rooted turnips and scabby potatoes and beets have been continued, while the spraying experiments of the station were confined to Bordeaux mixture and soda-Bordeaux mixture.

Soil fungicides for potato and turnip diseases (pp. 326-367).—In continuation of the experiments reported previously (E. S. R., 11, p. 751), the author reviews 6 years' experiments with potatoes in which was sought the means for the prevention of the potato scab. Differences are noted in the susceptibility of different varieties to this disease, and in the experiments conducted the author states that sulphur gave the best results, although the showing for this season was not very striking. An investigation was conducted in this connection to determine the susceptibility of other plants to these diseases, in which 9 species of plants belonging to the same botanical order as the potato and a number of other plants were grown on infested soil. With the exception of the radishes, beets, and potatoes, no scab was noted. Experiments on soil inoculation with the potato-scab fungus showed that the steam heating of potatoes for 20 minutes destroyed the fungus only to a limited extent, while there was almost entire absence of scab where the tubers were fed to cattle and the manure placed upon the land where potatoes were grown.

Experiments with soil rot of sweet potatoes (E. S. R., 11, p. 753) indicate that 300 or 400 lbs. of sulphur and kainit per acre will give

good results in combating this disease. Experiments with club root of turnips (E. S. R., 11, p. 750) have been continued, indicating that the application of 35 to 50 bu. of air-slaked lime per acre is a practical remedy. Irrigation seems to favor the development of this disease, and shading has but little effect upon it. The indications are that the germs of the disease will exist for a long time in the soil, even when weeds, upon which it abounds, are absent. Soil may be inoculated by using infested turnips, either applied directly or as manure from animals to which the clubbed turnips have been fed.

Experiments with Nitragin and other germ fertilizers (pp. 367-379).—A report is given of experiments in which Nitragin and Alinit were tested on a number of crops. The Nitragin experiments were conducted upon 11 varieties of leguminous plants, none of which gave particularly striking results in favor of the substance. As a possible explanation the author states that on the roots of all plants, both treated and untreated, tubercles were abundant, indicating the presence of a considerable amount of the organisms in the soil. Experiments with Alinit were conducted on a number of plants, but the results obtained gave no indication of any advantage in its use. An experiment was conducted with various substances which were thought to have an effect upon the germs in the soil whereby their growth and reproduction would probably be stimulated. The materials used were agar, egg albumen, asparagin, diastase, dextrin, and dyspepsin. The plants tested were peas, beans, and oats. There seems to have been no influence exerted on the crops by the different substances employed.

Experiments with beans (pp. 379-386).—In continuation of previous experiments (E. S. R., 11, p. 751), the author reports results with the eleventh and twelfth crops of beans grown continuously upon the same soil. Spraying experiments were conducted, but as the crop was free from disease there was little difference between the treated and untreated plats. This was true both where the soil was sprayed and where the plants were sprayed with fungicides. Experiments in planting beans at various depths of from 1 to 5 in. showed little difference between the shallower plantings; beans planted 5 in. deep did not grow.

Experiments with Lima beans and peas are reported in which the effect of treatment and planting on new soil was noted.

Experiments with tomatoes (pp. 387, 388).—Two varieties of tomatoes were planted upon soil which had borne tomatoes for the sixth successive time. Some of the plants were sprayed with Bordeaux mixture and soda-Bordeaux mixture. But as there was little fruit rot the results of spraying are not very striking. A considerably greater amount of green fruit was obtained at the end of the season from the sprayed than from the unsprayed plants.

Experiments with eggplants (pp. 388, 389).—The fifth consecutive

crop of eggplants is reported upon, but the yield of fruits was so small that conclusions can not be drawn from the investigation.

Experiments with cucumbers (p. 390).—Two varieties of cucumbers are reported upon which were sprayed with the fungicides above mentioned, in which Bordeaux mixture gave the better results. The effect of soil inoculation, in which soil from an area on which cucumbers had been previously grown was transferred to the hills, was investigated without any results.

Experiments with lettuce (pp. 390, 391).—Plats of Boston Market and Wonderful lettuce were sprayed with Bordeaux mixture and soda-Bordeaux mixture, 8 applications being given them. The rot was observed in the crown of the Wonderful early in July, and even the sprayed plants were not wholly exempt from it. At this time the other variety was in bloom and did not show any evidence of disease. The leaf spot (*Septoria lactucae*) was somewhat abundant, but, as it did not appear until after the plants had passed the marketable stage, was of little consequence. Inoculation experiments were conducted in which soil from an old lettuce bed was distributed evenly among the open rows in soil that had not previously grown lettuce. The experiment demonstrated that the leaf spot can be readily transmitted in this way.

Experiments with onions (p. 392).—A brief report is given upon experiments with onions grown for the third consecutive year on the same soil for the purpose of studying onion smut and other diseases. The crop was nearly a failure, and there was no smut on any of the plants where the disease had been introduced the previous year.

Experiments with beets (pp. 392, 393).—The author investigated the susceptibility of beets to the potato scab and also studied the influence of soil treatment upon its prevalence. The beets were severely infested with scab before the roots were large enough for table use. There seemed to be little difference in the susceptibility of the different varieties tested. The soil treatment appeared to indicate that the best results were obtained from the use of sulphur and then only after it had been in the soil for more than 1 year.

Experiments with sweet corn (pp. 393–395).—Experiments were conducted with Black Mexican and Egyptian corn in which cross fertilization of the 2 varieties was shown.

Experiments with Swiss chard and New Zealand spinach (pp. 395–398).—Experiments are reported with these vegetables in which Bordeaux mixture was used for preventing their diseases, especially in the case of the former. The results obtained were entirely favorable to the use of the fungicide.

Experiments in winter ridging of the soil (pp. 398–402).—Experiments are reported in which the effect of ridging the soil during the winter or allowing it to lie flat as shown by the occurrence of various

diseases are reported. The plants experimented with were tomatoes, turnips, potatoes, bush beans, peas, chard, Lima beans, and beets. The ridging of the soil for the added exposure does not show any marked advantage. There was a slight gain in the amount of crop with beets, bush beans, peas, and turnips, but an actual loss in case of tomatoes, potatoes, and Lima beans.

Experiments with spraying (pp. 402-404).—The formulas for the fungicides used in the foregoing experiments are given and the details of the experiments are briefly reviewed. So far as opportunity offered for comparison, the soda-Bordeaux mixture was about equal to the Bordeaux mixture in its efficiency.

Experiments with soil inoculation (pp. 406, 407).—These experiments were conducted with beans, peas, corn, Lima beans, cucumbers, lettuce, and tomatoes; with the exception of the lettuce, as noted above, there was little evidence that plant diseases can be transported by the method pursued.

Experiments with ornamental plants (pp. 408, 409).—Brief notes are given on experiments with a number of ornamentals, most of which were almost wholly free from fungus attacks.

Experiments with asparagus rust (pp. 410-413).—The author gives an account of the present season's investigations in spraying as a preventive of asparagus rust in continuation of experiments previously reported (E. S. R., 11, p. 753). Bordeaux mixture was the only fungicide used, and 5 applications were given during June and July. In August a number of plants were noticed to be injured by the fungicide, and half strength solution was used during August and September. A difference of 16.9 per cent was noticed in favor of sprayed plants. Observations made in the field seemed to indicate that the rust has not proved as harmful to the asparagus industry as was first expected. Clean culture and the use of commercial fertilizers have tended to produce a strong growth, so that the plants escaped serious injury.

Experiments with pear blight (pp. 414-417).—The third year's experiments with pear blight are reported. The results agree with those previously given (E. S. R., 11, p. 753), in that summer-pruned trees yielded better than others, but there is little in the way of conclusions to be drawn from the experiments thus far conducted.

Brief notes are given on the forcing of peaches attributed to causes similar to, if not identical with, peach yellows and on fungi as related to weather. During the season covered by the report there was an unusual precipitation in February and March, followed by a drought in April and May. As a result there was but slight occurrence of fungus diseases early in the season.

Cultures of Uredineæ in 1899, J. C. ARTHUR (*Bot. Gaz.*, 29 (1900), No. 4, pp. 268-276).—An outline is given of studies made by the author on the relationship between the aecidial and teleutospore forms

of a number of rusts. The experiments were, with a single exception, conducted in the greenhouse upon potted plants and, where the inoculation had been successfully made, results appeared in from 6 to 14 days.

Inoculations with the teleutospores of *Puccinia phragmitis*, a common species of rust on *Phragmites communis*, when sown on *Rumex crispus* and *R. obtusifolia*, produced abundant æcidia. Teleutospores of *Puccinia convolvuli* sown upon *Convolvulus sepium* produced æcidia, showing that this species of rust is autœcious. Æcidiospores from *Æcidium urticæ*, sown upon leaves of *Carex stricta*, in 11 days produced uredospores of *Puccinia caricis*. Sowings on another species of *Carex* failed to produce infection. Æcidiospores from *Euphorbia nutans* were sown upon that species, as well as upon *Euphorbia maculata*. The uredo occurred on *Euphorbia nutans*, followed by teleutospores. While not conclusive, the author thinks this indicates that *Uromyces euphorbia* is an autœcious species. Teleutospores of *Phragmidium speciosum* sown upon cultivated roses gave a Cæoma indistinguishable from *Cæoma miniata*, and it is assumed that the American rose Cæoma belongs wholly to *Phragmidium speciosum*. *Triphragmium ulmarie*, according to the author, a hitherto unknown rust in America, failed to produce infection except when sown upon *Ulmaria rubra*. Teleutospores of *Puccinia americana* from *Andropogon scoparius*, when sown upon *Pentstemon pubescens*, produced æcidia, and reciprocal infections of *Andropogon scoparius* with æcidiospores from *Pentstemon* were successfully made. Spores of *Æcidium lycopi*, sown on *Scirpus atrovirens*, produced the uredo form of *Puccinia angustata*. *Puccinia windsoriæ*, a very common rust on *Triodia cuprea*, is proved to be connected with the *Æcidium pteleæ* of *Ptelea trifoliata* by successful inoculations. The relationship between *Puccinia vilfæ* and *Æcidium verbenicola* is established by production of the uredo form of *Sporobolus longifolius* when inoculated with æcidiospores from *Verbena stricta*. In a similar way, connection between *Puccinia peridermiospora* and *Æcidium fraxini* is established, the teleutospores of the *Puccinia* readily producing the æcidia when sown upon *Fraxinus viridis*.

The smuts of Illinois agricultural plants, G. P. CLINTON (*Illinois Sta. Bul.* 57, pp. 289–360, pls. 10).—The author gives the results of studies made during the past 5 years to ascertain the kind of smuts infesting cultivated plants, the injuries inflicted by them, their life histories, and the most practical methods of preventing their ravages. The general structure of smuts is described, and directions given for their prevention.

Loose and hidden smuts of oats (pp. 297–316).—These 2 smuts, due to *Ustilago arenæ* and *U. levis*, have been under investigation, but the prevention and infection experiments were mainly confined to the

latter. The life histories of the fungi are described at some length, their effect on the host plants are stated, and the results of extended investigations to ascertain the percentage of damage done are given. The author concludes that about 6 per cent of the crop is annually destroyed by these diseases.

Investigations are reported on the effect of different times and depths of seeding on smut infection. The investigations seem to indicate that late planting tends to reduce the percentage of smut, while broadcasting the seed gave the lowest amount of the disease. In the case of seed broadcasted and lightly covered, the average amount of smut was 2 per cent. Seed covered to a depth of 1 in. averaged 6 per cent; 4 in., 10 per cent.

Investigations for the control and prevention of smut showed hot water and formalin proved the most efficient of the means tested. The author thinks the best procedure in most cases would probably be to treat only enough grain to obtain clean seed for another year.

Smut of tall oat grass (pp. 316, 317).—This smut (*U. perennans*), which was formerly thought to be identical with that of oats, is said to be less destructive to the flower parts of the grass than the loose smut of oats. The host plant of this species is not very commonly grown in Illinois, consequently the smut is of comparatively little importance.

Loose and covered smuts of barley (pp. 317, 318).—These 2 smuts (*U. hordei* and *U. nuda*) have been until recently considered the same species, the general appearance leading to this supposition. Both forms gain entrance to the host through the young tissues of the germinating seed. It has been shown that the spores falling between the open glumes are the chief source of infection and it is thought likely that with the loose smut the spores germinate and infect the seed coats with a hibernating mycelium which produces the disease the next year. On this account ordinary methods of treatment will prove failures.

Loose smut of wheat (pp. 318, 319).—This smut (*U. tritici*) is closely related, as its life history shows, to the smut of barley. An investigation by the author showed in 2 fields losses due to this source of 5 and 15 per cent, respectively. The author has conducted no experiments for its prevention but, based upon other recommendations, he suggests soaking the seed 4 hours in cold water, letting it stand 4 hours more in the wet sacks, and then treating it with hot water (133° F.) for 5 minutes. This treatment will probably kill some of the seed, hence about 1½ times the normal amount should be seeded.

Stinking smut of wheat (pp. 319–321).—This characteristic smut (*Tilletia foetens*) is comparatively well known and frequently very destructive. Hot-water treatment, as shown by experiments at the station, proved very efficient in its control.

Smut of Indian corn and teosinte (pp. 321–335).—The smut of these 2 plants infests the host on almost any part except the silk of the ears

and the underground roots. The general effect of the smut upon the host is described, and data cited from which it is concluded that the loss to the corn crop in the State amounts annually to about 2 per cent. Numerous experiments are cited for the prevention of the disease, showing that it can not be controlled by seed treatment. The corn smut seems to be more dependent upon its sporidia for its infection than any other smut of cereals. Infection takes place rarely, if at all, through the germinating seed, but is aerial and local. Winds serve as the carrying agent for the sporidia of the plants and land can not be selected that will be entirely free from smut. It is suggested that by avoiding the use of manure, planting the crop where smutted crops have not been grown the previous season, and careful cultivation would reduce the amount of smut to a minimum. Mutilation of plants at certain stages of their growth tends to largely increase the amount of smut. This is particularly true in the case of topping. Some observations indicate that different varieties of corn vary in their susceptibility to the disease, but this point must be confirmed by further experimental work.

Grain smut of sorghum and broom corn (pp. 335-346).—The grain smut of sorghum and broom corn (*Utricularia sorghi-vulgaris*) has been investigated at considerable length by the author. With broom corn this smut tends to produce an inferior brush, and while ordinarily fields do not have a very high percentage of smut, yet, on the whole, it is considered the worst fungus enemy of this crop. On the sorghum the smut tends to reduce the size and weight of the cane. Investigations showed that the smutted cane possessed a somewhat higher percentage of sugar, but the quantity of juice was reduced about in proportion to the reduction in the size and weight of the cane. The smut seriously affects the production of seed and, on the whole, lessens the yield of sorghum. It is recommended that sorghum and broom corn seed should be soaked for 15 minutes in water heated to 135° F. This method seems to be the most satisfactory and, as but little seed is required in planting these crops, the objection generally raised against the hot-water treatment of oats can not be urged.

Head smut of sorghum (pp. 346, 347).—This smut (*C. reiliana*) differs from the common grain smut of sorghum in converting the whole panicle into a large irregular mass. It has been reported as occasioning considerable damage in some localities, and in 1898 field experiments were conducted with a view of infecting the Orange variety of sorghum with this smut. Negative results were obtained in all the experiments, and it is thought probable that the variety was, to some extent at least, responsible for these results.

Grain smut of Hungarian grass (pp. 347, 348).—The presence of *Ustilago crameri* is noted in the spikes of cultivated millet. Generally only the lower parts of the glumes are destroyed, the fungus showing

through the thin membrane. This disease is not common, having been observed but once by the author in a field of German millet.

Leaf smut of timothy, redtop, and blue grass (pp. 348, 349).—The author reports the common occurrence in timothy, redtop, and sometimes on blue grass of *U. striæformis*. It is generally found in the late spring or early summer occurring on the leaves, sheaves, and rarely in the inflorescence. Affected plants are smaller than healthy ones and often, especially in the case of blue grass, are so inconspicuous as to be easily overlooked. The fungus is not uncommon and frequently said to do considerable damage, one estimate placing a loss of 30 per cent due to its presence.

Variations in the amount of leaf curl of the peach in the light of weather conditions, A. D. SELBY (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 98-104).—In continuation of his observations upon the leaf curl of the peach (*Eccouscus deformans*) (E. S. R., 10, p. 557), the author gives an account of a study of the relationship between the weather conditions in the spring of the year and the amount of leaf curl. The data cover the seasons from 1893 to 1899. The author concludes that in northern Ohio the April weather is very largely responsible for the serious outbreaks of leaf curl. It is not prevalent there to a damaging extent except in years with cool, rainy, and cloudy weather. It is believed that the profitable spraying for leaf curl may be predicted with fair certainty from the temperature and rainfall of the first half of April.

A parasite of carnation rust, F. H. BLODGETT (*New York State Sta. Bul.* 175, pp. 13, pls. 3).—The occurrence of a fungus parasite of carnation rust in several greenhouses in New York is reported. While not naturally very effective as a check, by the use of artificial cultures or inoculations the author believes that some benefit might be derived from its presence.

The parasite, which has been determined as *Darluca filum*, is described at some length. Its presence is best determined by microscopic examination. The same fungus is said to infest the rust of asparagus, and it is suggested that by growing garden asparagus in houses a sufficient abundance of fungus might be obtained to check the ravages of the rust on the carnation.

Plasmodiophora brassicæ, S. NAWASCHIN (*Flora*, 86 (1899), pp. 404-427, pl. 1; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 2, p. 239).—A series of observations on the minute structure of this parasite and on the changes which it undergoes during its intercellular life are reported. In the amœba stage it exhibits a decidedly abnormal kind of indirect division, while in the spore-forming plasmodium the division of the nucleus is of a typical karyokinetic character. The differentiated group of infected parenchymatous cells of the host arise by repeated division of the cells first infected. In the course of the

growth of this swelling, there arise in infected cells a number of multi-nucleated amœba which at first do not coalesce into a plasmodium. The formation of the plasmode is preceded by characteristic changes in the structure of the amœbæ and their nuclei and takes place only after the complete exhaustion of the nutrient cell. During the vegetative period of its development the parasite does not kill the nutrient cell but simply causes hypertrophy.

Investigations of plant diseases, A. D. SELBY (*Ohio Sta. Bul.* 111, pp. 93-142, figs. 12).—This bulletin is a summary of the work carried on at the Ohio Station in the control of the fungus diseases of plants and was prepared as a part of the collective exhibit of the American experiment stations at the Paris Exposition in 1900.

Fungus foes of vegetable fruits, B. D. HALSTED (*Pennsylvania Dept. Agr. Bul.* 59, pp. 39, figs. 20; *Rpt.* 1899, pp. 573-605, figs. 20).—A somewhat popular bulletin treating of the more common vegetable fruits, in which their diseases are briefly described and suggestions given for their prevention.

Plant diseases investigated at the botanical laboratory of the Institute Agricole during 1899, E. MARCHAL (*Bul. Agr. [Brussels]*, 16 (1900), No. 1, pp. 9-21).

Smut of cereals, E. THOMAS (*Bul. Roy. Soc. Agr. L'Est Belg.*, 1899, pp. 157, 158).

A review of the stinking smut of wheat in Belgium in 1898, G. STAES (*Tijdschr. Plantenziekten*, 5 (1899), Nos. 5-6, pp. 170-176).

Smut diseases of plants, H. VANDERYST (*Extr. Bul. Agr. [Brussels]*, 15 (1899), pp. 46).

Wheat smut, A. BOURGUE (*Jour. Soc. Agr. Brabant-Hainaut*, 1899, pp. 272, 273).

The smuts of Bermuda grass and their distribution, P. MAGNUS (*Les ustilaginées du Cynodon dactylon et leur distribution géographique. Lons-le-Saulnier: Declume*, 1899, pp. 8).

A bacterial disease of beans, G. DELACROIX (*Monit. Hort. Belg.*, 1900, pp. 26, 27).

A spot of tobacco leaves, A. SPLENDRE (*Giorn. Il Tobacco*, 1899, No. 34; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 11, p. 379).—The spots are said to be dry, olive-brown, and irregular and contain the mycelium of a fungus. Leaves placed in a moist chamber developed an *Alternaria* indistinguishable from *A. tenuis* and a *Macrosporium*. Whether the fungi were the cause of the spots was not determined. In Java a similar disease is common and is most abundant during rainy seasons.

Influence of seed parasites on the growth of sugar beets, J. STOKLASA (*Sucr. Belge*, 28 (1899), pp. 105-108).

A bacterial rot of onions, F. C. STEWART (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 43-46, pls. 2).—The substance of this paper has been already noted (*E. S. R.*, 12, p. 56).

Ergot from wild rice, R. H. DENNISTON (*Pharm. Rev.*, 18 (1900), No. 3, pp. 118, 119).

Two new diseases of Phlox, J. RITZEMA-BOS (*Tijdschr. Plantenziekten*, 5 (1899), No. 2, pp. 27-32).—Describes attacks of *Tylenchus devastatrix*, *Septoria phlogis*, and *Leptosphaeria phlogis*.

A new parasite on leaves of Vinca major, F. CAVARA and P. A. SACCARDO (*Nuovo Gior. Bot. Ital.*, n. ser., 6 (1899), pp. 7; *abs. in Bot. Centbl.*, 82 (1900), No. 5, pp. 141, 142).—On leaves of *Vinca* attacked by *Puccinia berkeleyi* the authors report finding a new Tuberculina, to which the name *T. sbrozii* is given.

A dangerous parasite of fruit trees, J. RITZEMA-BOS (*Tijdschr. Plantenziekten*, 5 (1899), No. 5-6, pp. 168, 169).—Describes *Agaricus squarrosus*.

Peach leaf curl and its prevention, G. STAES (*Tijdschr. Plantenziekten*, 5 (1899),

No. 3-4, pp. 135-138).—Describes *Exoascus deformans* and quotes from another source (E. S. R., 10, p. 557) that spraying with Bordeaux mixture greatly reduced the amount of disease.

The serious injury to sweet cherries in the Rhine Provinces, P. SORAUER (*Naturw. Wehnschr.*, 15 (1900), No. 12, pp. 133-135).

A bacterial disease of syringa, J. RITZEMA-BOS (*Tijdschr. Plantenziekten*, 5 (1899), No. 5-6, pp. 177-183).—A disease of syringa which is attributed to bacteria is described. Inoculation experiments were successfully made. The organism is said to be closely related to *Bacillus fluorescens liquefaciens*; forms a yellow pigment on bouillon gelatin, and gives a slight bluish fluorescence.

Notes on the red rot of spruce, G. STAEN (*Tijdschr. Plantenziekten*, 5 (1899), No. 5-6, pp. 183-192).—Notes the attack of *Agaricus melleus* and similar fungi on spruce and firs.

A disease of plane trees in Paris, A. GIARD (*Bul. Arboricult. et Floricult.*, 1899, pp. 356-359).

An epidemic disease of the common alder (*Alnus glutinosa*), P. NYPELS (*Bul. Soc. Belge Micros.*, 25 (1898-99), No. 8, pp. 95-104, pl. 1).

Combating pine leaf cast, WEBER (*Forstw. Centbl.*, 21 (1899), No. 12, pp. 625-634).—An account is given of experiments with Bordeaux mixture, and Bordeaux mixture with sugar and with gluten for the prevention of the leaf cast of pines caused by *Lophodermium pinastri*. The use of the first fungicide was the most successful.

Combating some coffee parasites, G. D'UTRA (*Bol. Inst. Agr. São Paulo*, 10 (1899), No. 11-12, pp. 778-795).

Concerning black rot, A. JACZEWSKI (*Westnik Winodelia*, 1899, No. 3, pp. 139-145; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 8, pp. 263, 264).—The form of black rot in the Caucasus is said to differ materially from that occurring in France. The parasitism of *Phoma reniformis* in the Caucasus is affirmed. Bordeaux mixture is said to have proved the most efficient fungicide for use against black rot.

Experiments in the treatment of black rot in 1899, J. B. SENDERENS (*Vigne Franc.*, 1900, No. 1, pp. 7, 8).

Grape white rot, B. BARNA (*Bot. Centbl.*, 81 (1900), No. 10, pp. 331, 332).—Notes the occurrence of *Charrinia diplodiella* in Austro-Hungary.

Combating grape mildew or oidium, J. SCHUSTER (*Allg. Wien Ztg.*, 1900, No. 6, pp. 52, 53).

The true mildew (*Oidium tuckeri*), J. MORGENTHAUER (*Aarau: E. Witz*, 1899, pp. 28; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 5, p. 157).—A number of fungicides were tested with more or less success. A mixture of 1 kg. soft soap, 0.5 kg. potassium sulphid, and 100 liters water is recommended. Winter washing of the vines with either of the following mixtures is advised: 10 kg. lime, 6 to 10 kg. iron sulphate, 100 liters water; 10 to 15 per cent solution of iron sulphate; or 5 per cent solution of sulphuric acid.

Permanganate of potash for grape mildew, C. TRUCHOT (*Vigne Amer. et Viticult. Europe*, 23 (1899), No. 10, p. 300).—Spraying vines with a mixture of 125 gm. potassium permanganate, 3 kg. lime, and 100 liters water is recommended for destroying oidium.

Causes of the stunted growth of vines, J. PERRAUD (*Prog. Agr. et Vit.* (Éd. L'Est), 21 (1900), No. 23, pp. 667-670).—The author discusses numerous causes for the stunted growth of grapevines, among them being fungi, physiological disturbances, etc.

Plant parasites of roses, F. RICHTER VON BINNENTHAL (*Mitt. K. K. Gartenbau Gesell. Steiermark*, 1900, No. 6, pp. 100-104).

Soil fungicides for potato and turnip diseases, B. D. HALSTED (*New Jersey*

Stas. Special Bul. 8, pp. 43, pls. 8).—The investigations reported in this bulletin are noted on page 351 from another source.

Notes on Bordeaux mixture, G. STAES (*Tijdschr. Plantenziekten*, 5 (1899), No. 3-4, pp. 130-134).—Notes are given on the relative adhesiveness of Bordeaux mixtures made by different formulas and the effect of Bordeaux mixture upon a number of varieties of potatoes. Most of the information is compiled.

ENTOMOLOGY.

The destruction of mosquitoes in the city, C. FERMI and S. LUMBAO (*Centbl. Bakht. u. Par.*, 1. Abt., 28 (1900), No. 6-7, pp. 179-185).—The authors give brief biological notes on the mosquitoes which most commonly infest cities. As insecticides against mosquito larvæ, the authors used petroleum and chrysanthemum powder with good success. Several substances were experimented with for the purpose of discovering means for the prevention of the too rapid evaporation of petroleum from the surface of infested water. The substances which were spread upon the surface of the petroleum for this purpose were lanolin, vaseline, tar, naphthalin, olive oil, flaxseed oil, castor oil, and lard. Vaseline and tar spread rapidly over the surface of the oil without coagulating. A large number of plant substances were tried in combination with chrysanthemum powder in the destruction of mosquito larvæ. For the destruction of adult mosquitoes the authors tried fumigation with a number of substances, among which the following gave the best results: Chloroform, turpentine and vinegar, sulphuric ether, tobacco fumes, and eucalyptus fumes. During the experiments with petroleum it was found that 5 cc. per square meter of water surface killed all mosquito larvæ. It was not found necessary to renew the kerosene upon the surface oftener than once in 14 days.

Some insects injurious to garden crops, F. H. CHITTENDEN (*U. S. Dept. Agr., Division of Entomology Bul. 23*, n. ser., pp. 92, figs. 23).—*A new vine borer of Lima beans (Monoptilota nubilella)* (pp. 9-17).—This insect produces gall-like swellings upon the stems of Lima beans. Its present distribution seems to be from Maryland, Virginia, and the District of Columbia southward to Florida and Alabama. The author gives a description of the species in its various stages. The insect attacks Lima bean vines at almost any point along their length, and it was observed that vigorous plants were able to survive the attack while weak ones suffered to a much greater extent. The moth deposits several eggs on each vine. The species is partly double-brooded, the second generation in the District of Columbia being a small one. The greater part of the first generation probably winters over. No natural enemies of the first generation were discovered. A single parasite was reared from a specimen of the second generation and was identified as *Omphale livida*. The remedial measures sug-

gested are trimming and destroying terminal portions of infested vines and removing larvæ from the lower portions of the stem by longitudinal cuts.

The smaller cornstalk borer (Elasmopalpus lignosellus) (pp. 17-22).—Specimens of this insect have been received from Georgia, South Carolina, North Carolina, Florida, Kansas, Texas, and Maryland. The species has also been observed in Indiana. The author gives a description of the moth and of the early larval stages. The only known natural enemy of this insect is *Orgilus mellipes*. The insect has been observed hibernating in all 3 stages. The remedies suggested against this species are plowing up and burning the corn stubble or other infested material, and rotation with some crop not attacked by this species.

The pale-striped flea-beetle (Systema blanda) (pp. 22-29).—A description is given of the adult and larval stages. The distribution of this species includes a large portion of the country from New England to the Gulf States and west to the Dakotas and Colorado and perhaps California. The native food plants of this flea-beetle seem to be especially ragweed and cocklebur, but it has recently attracted some attention as an enemy of beans and corn. The species hibernates as a beetle, and appears in the vicinity of the District of Columbia early in June. The larvæ feed below ground and probably have a wide range of native food plants. No insect enemies of the species have been observed, but the chipping sparrow and the yellow-winged sparrow have been seen eating the adult beetles. As a remedy against this insect the author recommends spraying with Bordeaux mixture and Paris green.

Observations on the bean leaf-beetle (Cerotoma trifurcata) (pp. 30, 31).—This species seems to be increasing in abundance and injuriousness. Serious outbreaks have been reported from various parts of Virginia, Alabama, Maryland, and Missouri.

Notes on the imbricated snout beetle (Epicarnus imbricatus) (pp. 31, 32).—Adult beetles of this species were observed feeding on bush beans and eating the blossoms of the Lima bean. One specimen of the beetle in a rearing jar was destroyed by *Sporotrichum globuliferum*.

A new tingitid on bean (Gargaphia angulata) (pp. 32, 33).—This insect was reported from Auburn, Ala., as injurious to the leaves of beans. On examination it was found to be a new species, which has recently been described.¹

The destructive green-pea louse (Nectarophora destructor) (pp. 33-37).—This insect has committed serious depredations on peas from Nova Scotia and Canada to Virginia and Maryland. No alternate food plant for the species has thus far been discovered. The following parasites have been reared from this species: *Praon cerasaphis*, *Aphidius fletcheri*,

¹ Canad. Ent., 31 (1899), p. 301.

and *Isocratus vulgaris*. The only remedies thus far suggested against this insect are the use of kerosene emulsion and the rotation of crops.

A note on the Mexican bean weevil (*Spermophilus pectoralis*) (pp. 37, 38).—The species is known to inhabit Nicaragua, Guatemala, Panama, Mexico, Peru, and Brazil. The eggs are deposited in considerable numbers, from 50 to 100 on each bean. It is suggested that the species may in time come to infest the Southern States.

The cabbage curculio (*Ceutorhynchus rapæ*) (pp. 39–50).—This insect is reported as injurious to cabbage, kale, turnip, and horse-radish. Its preferred native food plant seems to be hedge mustard. The author describes the insect in its different stages and gives bibliographical notes. In the hedge mustard the larvæ cut holes through the stalks as they approach maturity. Sixty or more larvæ have been observed in a single stem of this plant. The beetles were observed feeding upon cauliflower and cabbage, eating the edges of the leaves. Near Washington the beetles appear in April and deposit their eggs, preferably in the hedge mustard. The egg period varies from 5 to 8 days. The larvæ feed within the stems and leaf stalks and complete their growth in about 3 weeks. Pupation takes place under the ground, and the length of the pupal period is from 5 to 8 days. The only parasite reared from this species was *Omphala livida*. The remedies suggested include the destruction of the wild food plants of the species used as trap crops, the use of hot water and bisulphid of carbon poured on ground infested with larvæ, and the poisoning of the beetles by arsenical sprays.

Remarks on the food habits of species of Ceutorhynchus (pp. 50–52).—Brief notes are given on the host plants of certain native and foreign species of this genus.

Additional notes on the imported cabbage webworm (*Hellula undalis*) (pp. 53–61).—The first appearance of this insect in the United States was in 1895. It is probably distributed at present throughout the Gulf region and is reported as very destructive in western Australia. In breeding cages the larvæ feed to considerable extent on shepherd's purse. The insect has been reported from a number of new localities in Georgia and Alabama, and notes are given on its injuriousness during the year 1899. It was reported as feeding to some extent on the common garden purslane. Adult moths develop from the larvæ of the first generation by July 22. The egg period was found to be 3 days, the larval period 18 days, and the pupal period 6 days, making the entire life cycle 27 days. Three parasites were raised from the webworm: *Meteorus vulgaris*, *Temelucha macer*, and *Erorista pyste*. The remedies suggested are the planting of an excess of seed with a view to destroying the injured part of the crop later and growing cruciferous trap crops to be freely sprayed with Paris green.

The common rhubarb curculio (*Lixus concavus*) (pp. 61–69).—A seri-

ous outbreak of this beetle on rhubarb occurred in May, 1899, in Tennallytown, D. C. The distribution of this species includes the greater portion of the United States east of the Mississippi Valley. The more common native food plants are a species of dock and *Helianthus grosseserratus*. The beetle hibernates in the adult stage in the District of Columbia. The eggs are deposited singly in small cavities constructed in the stems of food plants. The egg period is found to be about 8 days and the larval stage about 2 months. Eggs deposited in rhubarb apparently do not develop. The remedies to be applied against this species are hand picking of the beetles and destruction of the native food plants after the deposition of the eggs.

The strawberry flea-beetle (Haltica ignita) (pp. 70-78).—This species is native to America and is distributed throughout the United States. Near Washington the beetles appear in May. The duration of the egg stage was found to be about 6 days; that of the larval stage, 11 days. There are apparently 2 generations annually in the vicinity of Washington. No insect enemies of this species have been discovered. The remedies suggested are spraying with arsenicals, either Paris green or arsenate of lead, both upon the cultivated and wild-food plants.

The fall army worm in 1899 (Laphygma frugiperda) (pp. 78-85).—This insect was unusually injurious during 1899. It was reported as attacking *Agrostis stolonifera*, *Euchena mexicana*, clover, grass, wheat, and a great variety of cultivated crops. A brief account is given of its distribution, life history, and habits, together with a short description of the species in its different stages. The observed natural enemies are the English sparrow, flicker, and *Winthemia quadripunctulata*. It is suggested that lawns might be freed from the caterpillars by the use of kerosene emulsion. Other remedies suggested are the use of poisoned baits, spraying trap crops with arsenicals, and the destruction of the volunteer grain and wild grasses.

The strawberry crown moth (Sesia rutilans) (pp. 85-90).—This insect has caused considerable damage to the strawberry, blackberry, and raspberry in California. A brief description of it is given. The most successful remedy appears to be the submerging of affected fields. Ordinary insecticide applications seem to be useless.

The black gooseberry borer (Xylocrinus agassizii) (pp. 90-92).—This insect was reported by Fletcher as having been introduced into British Columbia from Oregon and as being injurious to gooseberry bushes. A serious infestation by it was found in an Oregon nursery. The species had previously been considered rare. The only remedy suggested is the cutting out and destruction of the injured plants as soon as infestation is discovered.

Some insect pests of Salt River Valley and the remedies for them, T. D. A. COCKERELL (*Arizona Sta. Bul. 32, pp. 269-295*).—The author reports that Salt River Valley is comparatively free from insect

pests, no scales being found on either olive or orange trees. It is suggested that the isolation of the valley from other cultivated areas and the burning effects of the sun constitute the main reasons for this immunity. The author recommends strict quarantine measures regulating the importation of fruit and ornamental trees. A number of native scales were found in this region, but they do not seem to be especially injurious, and it is thought that this condition is brought about by the natural enemies of scale insects. Notes are given on a number of the more important insects of Salt River Valley, among which may be mentioned *Pycnoderes quadrimaculatus*, San Jose scale, *Colias eurytheme*, the corn worm, *Drosophila ampelophila*, the pear-leaf blister mite, and the Bryobia mite. Approved remedies are suggested in connection with a discussion of each insect pest.

Report of the entomologist, J. B. SMITH (*New Jersey Stat. Rpt. 1899, pp. 421-512, figs. 44*).—Brief notes are given on a large number of injurious insects affecting various garden and field crops, among which may be mentioned the pea-plant louse, the peach thrips, codling moth, pear slug, peach-twigg borer, woolly aphis, San Jose scale, Hessian fly, fall army worm, bagworms, and the tulip soft scale. The author discusses various insecticides, among which may be mentioned arsenate of lead, Green Arsenoid, potash soap, kerosene, crude petroleum, and whale-oil soap. The experimental orchard has been increased in size. Experiments made there with various insecticides, especially against the San Jose scale, are reported. General recommendations are given regarding the time and method of making various insecticide applications to different plants. It is urged that spraying should not be done except for specific reasons. A single Vermorel nozzle or a group of 3 such nozzles is recommended as the best for general purposes.

Observations have been continued on the San Jose scale. This was not affected by the unusually low temperature which occurred during the preceding winter. Unusually large swarms of larvæ appeared about June 15 and lasted for somewhat more than 10 days. The second brood appeared late in July, the third during the middle of September, and the fourth late in October. This insect is now reported from every county in the State. Kerosene was used for the most part on apple and pear trees and less frequently on peach trees with only rare cases of injury to the trees. Further experiments were made with crude oil, in an orchard of dwarf Duchess pears and apples. A portion of the orchard had been sprayed in March with a 30 per cent mixture of crude petroleum and water, but this application had been irregular and unsatisfactory. It had been intended to treat the dwarf Duchess pears with a 15 per cent mechanical mixture of crude petroleum and water. Preliminary tests, however, indi-

cated this to be an unsafe combination, and kerosene was substituted for the crude oil on the majority of the trees. Spraying was begun June 15. A detailed account of experiments in this orchard is given from which, in connection with other work done by the author, the following conclusions may be drawn:

"In the treatment of San Jose scale it was found that kerosene is a very efficient remedy, but when carelessly used it will injure trees. Whale-oil soap will also injure fruit buds if applied early in the winter at a greater strength than 1 lb. to the gallon of water. Crude petroleum was tried on all common orchard fruits except the cherry without in any instance causing injury. This substance is recommended as having the following advantages: Great penetrating power, lasting effect, and causing a slight temporary change in the color of the bark which enables one to see at once whether or not the application has been thorough. For work on the larvæ of the San Jose scale at a time when the leaves are in foliage, kerosene or crude petroleum in a 10 per cent mechanical mixture with water is effective, but crude oil is not to be recommended for this purpose on account of its bad effect on the foliage."

Among the natural enemies of the San Jose scale the author mentions *Erochonus tripustulatus* and *Pentilia misella*.

Report of acting field director [of Gypsy Moth Commission], A. H. KIRKLAND (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 356-383, pls. 3*).—In January part of the force was utilized in cutting over infested woodlands and in February and March considerable cutting and burning was done in various towns. During the year 2,300,000 trees were banded with burlap. In June 20 gangs of men operated with spraying outfits. The spraying was especially effective, since the season was unusually clear and dry. The inspection of burlaps was carried on during July and part of August. During the autumn months considerable attention was given to burning brush and the destruction of eggs.

As a result of sending circulars concerning the gypsy moth outside of the known limit of infestation, 2 new colonies were found—one at Newton and the other at Georgetown. Gangs of workers were at once dispatched to these 2 new centers of infestation and stringent measures were taken to exterminate the moth in these localities. Detailed notes are given on the progress of the work in the various infested towns. The general condition is said to be better and more encouraging than ever before.

Birds as destroyers of hairy caterpillars, E. H. FORBUSH (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 316-337*).—The present article is limited to observations on birds which feed upon the gypsy moth, the brown-tail moth, the tent caterpillar, and the forest tent caterpillar. A number of places were selected where serious outbreaks of one or more of these insects had occurred and observers were stationed there to record the frequency of the visits of different birds to infested trees and, when possible, the number of insects eaten by these bird visitors.

The following birds were observed carrying hairy caterpillars to their young: Black-and-white warbler, blue jay, scarlet tanager, wood thrush, chickadee, yellow-throated vireo, red-eyed vireo, crow, cat-bird, black-billed cuckoo, yellow-billed cuckoo, yellow warbler, and chestnut-sided warbler. A pair of red-eyed vireos made 125 visits in 10 hours and a pair of rose-breasted grosbeaks made 426 visits in 11 hours to secure caterpillars for their young. The birds which are most concerned in the destruction of hairy caterpillars belong to the following families: Cuckoos, woodpeckers, flycatchers, crows, orioles, sparrows, tanagers, vireos, warblers, mocking thrushes, wrens, titmice, and thrushes. The author gives a list of 47 birds which feed on these caterpillars. Many birds prefer smooth caterpillars when they can be had. A new colony of gypsy moths discovered in Georgetown, Mass., was seen to be visited by large numbers of several species of birds, and it is believed that the injuries from the gypsy moth were considerably reduced by the help of these birds.

Bee wintering, A. GALE (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 635-638, pl. 1).—The author states that in the Australian Colonies bees are exposed to greater dangers in the warm months than in the cold months. It is recommended, therefore, that beehives and houses be constructed especially for the purpose of properly protecting bees during the hot season. The same mechanical devices which prevent the absorption of heat also prevent the radiation of heat.

The pollination of fruit by honey-bees, W. R. LAZENBY (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 68-73).—This is essentially the same as an article previously published by the author (*E. S. R.*, 11, p. 956).

Protective powers of insects against cold, H. ROEDEL (*Helios*, 17 (1900), pp. 69-78).—A discussion of recent literature on this subject, especially that of the extensive investigations of Bachmetjew.

Entomological notes on specimens received during 1899, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 639-651, pls. 2).—In this article the author gives economic and biological notes on the following insects: Ambrosia beetle (*Xyleborus solidus*); *Tenebrio molitor*; *Ethemaia sellata*, injurious to garden crops in the caterpillar stage; *Prostaglyeus comosus*, attacking the foliage of fruit trees; *Desiantha caudata*, also injurious to fruit trees; *Paramorpha aquilina*, injurious to oranges; *Nola metallopa*, feeding upon the foliage of eucalyptus; *Nerius lineolatus*, injurious to the banana; Cattleya fly (*Cecidomyia* sp.); and *Pochazia australis*.

Notes on insects of the year 1899, F. L. HARVEY (*Maine Sta. Bul.* 61, pp. 31-42, figs. 2).—This bulletin contains brief notes on the chinch bug, elm plant louse, forest tent caterpillar, Buffalo carpet beetle, etc. The brown-tail moth (*Euproctis chrysorrhæa*) is reported as occurring in South Berwick and Kittery Point. At the latter locality the insect is supposed to have been introduced two years before on household goods shipped from Cambridge, Mass.

Insects of New Jersey, J. B. SMITH (*New Jersey State Bd. Agr. Rpt.* 1899, pp. 755, figs. 328).—A popular account is given of the life history, habits, and classification of insects in general, the injury caused by insects, and methods of preventing such damage. The greater part of the article is occupied with a catalogue of the insects found to occur in New Jersey with a brief characterization of the different orders and families, and notes on the more important injurious species.

New insect pests of the year 1899, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 34-37, figs. 4).—Brief notes on the asparagus beetles (*Crioceris asparagi* and *C. 12-punctata*), *Plutella cruciferarum*, the pea louse, and the corn aphid.

Recent additions to the list of injurious insects of Canada, J. FLETCHER (*Trans. Roy. Soc. Canada, 2. ser., 5 (1899-1900), Sec. IV, pp. 207-231, figs. 18*).—The author presents observations on the habits and economic importance of a number of injurious insects, among which the following may be mentioned: American frit fly, wheat-stem sawfly, *Hadena arctica*, *Aphis rumicis*, *A. brassicae*, *Psila rosae*, *Noctua fen-nica*, *Eriopeltis festucae*, San Jose scale, *Magdalis senescens*, *Anthonomus signatus*, apple maggot, clover mite, and *Psylla piricola*.

Notes on the geographical distribution of injurious Hemiptera, H. OSBORN (*Proc. Soc. Prom. Agr. Sci. 1899, pp. 59-62*).—This article contains a brief outline of the distribution of the various families of this order of insects.

The Hessian fly, G. MCCARTHY (*Bul. North Carolina State Bd. Agr., 21 (1900), No. 6, pp. 14-16*).—Popular notes on the life history and habits of this insect, together with brief descriptions of the most approved way of controlling it.

The diseases and insects affecting apple trees in North Carolina, with suggestions for their destruction, G. MCCARTHY (*Bul. North Carolina State Bd. Agr., 21 (1900), No. 7, pp. 28-39, figs. 18*).—Brief notes on insecticides, fungicides, and the spraying machinery necessary in the treatment of apple diseases.

Report on the brown-tail moth, E. W. WOOD ET AL. (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 384, 385, pl. 1*).—It is stated that the area of infestation of this insect is rapidly increasing and that no colony has been exterminated since the insect became well established.

Report of acting field director, A. H. KIRKLAND (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 386-388*).—The sum of \$10,000 was expended during 1899 in the destruction of the brown-tail moth. In April many webs were destroyed in the worst infested localities; spraying with arsenate of lead was carried out in June with good success. During November the majority of the webs in Medford, Malden, and Everett were destroyed.

The area of infestation by the brown-tail moth in the fall of 1896 was about 29 square miles. By the fall of 1899 this area had increased to 928 square miles. It is stated that the insect will probably become distributed in the near future over the whole State.

The gypsy moth in the legislature, M. A. MORSE (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 37-43*).—This is a brief statement of the investigation of the gypsy moth question before the legislative committee on this subject.

Report of the committee on the gypsy moth, insects, and birds, E. W. WOOD ET AL. (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 341-351, pls. 2*).—The committee presents a report of expenditures made and work performed during the year 1899. The work of the gypsy moth commission was carried out along lines similar to those adopted in previous years.

The committee recommends an attempt to secure the cooperation and aid of the National Government in exterminating the gypsy moth. It is maintained that although the work against the gypsy moth has been somewhat handicapped by insufficient and delayed appropriations that constant progress is being made toward the desired end.

Report of the entomologist, C. H. FERNALD (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 352-355, pl. 1*).—The author states that "there is no longer any question in the minds of those who have made a careful personal investigation of the work throughout the infested territory that the gypsy moth can be exterminated." An estimate is made of the amount of money which will be required in future years for the complete extermination of the insect.

The elm-leaf beetle in Massachusetts, A. H. KIRKLAND (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 289-300, figs. 4*).—Notes on the habits, life history, food plants, natural enemies, and remedies for this insect.

The extermination of the enemies of coffee, G. D'UTRA (*Bol. Inst. Agr. São Paulo*, 10 (1899), No. 11-12, pp. 778-785).—The author discusses the appearance, life history, and habits of *Dactylopius destructor* and gives brief notes on other related scale insects. Tables are given showing the amount of cyanid of potash, sulphuric acid, and water to be used in giving the fumigation treatment to infested trees of different sizes. Formulas are given for other insecticides to be used against scale insects, the insecticides containing sulphate of copper, essence of terebinth, kerosene, and water.

Coccidæ of Kansas, III, S. J. HUNTER (*Kansas Univ. Quart.*, 9 (1900), No. 2, pp. 101-107, pl. 1).—Brief descriptive and biological notes on species of *Chionaspis* and *Pulvinaria*.

Remarks on Indian scale insects, with descriptions of new species, F. E. GREEN (*Indian Mus. Notes*, 5 (1900), No. 1, pp. 1-13, pls. 2).—Descriptive and biological notes are given on species of *Aspidiotus*, *Florinia*, *Chionaspis*, *Lecanium*, *Pulvinaria*, *Ceroplastes*, *Eriochiton*, and other genera. A number of species are described as new, and notes are given on their economic importance and life history. Among the new species mention may be made of *Chionaspis separata*, which occurs on tea leaves; *Lecanium watti*, occurring on the twigs and stems of the tea plant; and *Eriochiton theae*, which is found upon the branches and twigs of the tea plant.

Harpalus caliginosus as a strawberry pest, with notes on other phytophagous Carabidæ, F. M. WEBSTER (*Canad. Ent.*, 32 (1900), No. 9, pp. 265-271, pl. 1).—In several localities in Ohio this beetle was found to attack strawberries, injuring or destroying in some cases a large percentage of the crop. The damage was done during the night and the beetles seemed to prefer the seeds, although in securing the seeds the pulp was necessarily rendered unmarketable. Brief notes are presented on the literature concerning similar habits of related species.

Recent experiments in the destruction of phylloxera upon grapevines, G. COUANON ET AL. (*Bul. Min. Agr. [France]*, 19 (1900), No. 1, pp. 135, 136).—A number of experiments were tried by the authors in ridding grapevine plants of the phylloxera. Plants were immersed in hot water for 5, 4, and 3 minutes for different lots. The water in each case had a temperature of 53° C. at the beginning and 51° at the end of the immersion. The plants were not injured in any case by the immersion in hot water and the phylloxera were killed in both the adult and egg stages.

Fumigation for insect pests, W. E. BEAR (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. II, pp. 263-291, figs. 3).—This article contains a descriptive and historical account of fumigation with hydrocyanic-acid gas, bisulphid of carbon, and tobacco, as practiced in the United States, Cape Colony, New Zealand, Victoria, New South Wales, South Australia, France, Belgium, and England.

Nursery fumigation and the construction and management of the fumigating house, W. G. JOHNSON (*Pennsylvania Dept. Agr. Bul.* 56, pp. 24, figs. 7; *Rpt.* 1899, pp. 606-621, figs. 7).—The bulletin contains a general account of the history of fumigation for the destruction of insects, the necessary equipment for this operation, the construction of the fumigating house, preparation of trees for fumigation, the method of generating the gas, and the effect of gas upon various kinds of nursery stock.

Cyaniding tents, A. H. BENSON (*Queensland Agr. Jour.*, 7 (1900), No. 1, pp. 39-41, pl. 1).—The materials and methods of making tents for cyaniding fruit trees.

Spraying crops for profit, S. T. MAYNARD (*Massachusetts State Bd. Agr. Rpt.* 1899, pp. 261-272, pls. 4, figs. 6).—This is a popular statement of methods and remedies to be applied in the treatment of the insect pests of various economic plants.

Crude petroleum as an insecticide, J. B. SMITH (*Proc. Soc. Prom. Agr. Sci.* 1899, pp. 63-67).—The essential facts of this article have been previously noted from another publication (*E. S. R.*, 11, pp. 760-762).

Nematodes and ammonia salts, C. SCHREIBER (*Rev. Gén. Agron. Louvain*, 9

(1900), No. 3, pp. 97-102).—It was found upon experiment that both chlorid and nitrate of ammonia are efficient agents in the destruction of nematodes. The rapid diffusion of nitrate of ammonia renders its effect less durable. In a dry condition it was much more effective than ammonia in a gaseous form.

FOODS—ANIMAL PRODUCTION.

Commercial beef extracts, T. MACFARLANE and A. MCGILL (*Lab. Inland Rev. Dept., Canada Bul. 62, pp. 22*).—The composition of a considerable number of beef extracts and similar products is reported. Methods of analysis are described and discussed at some length, and also the food value of these materials.

“It is evident that the flesh bases can not be called food stuff in the proper sense of that term. They represent a stage of the process by which complex nitrogen compounds are changed to simple ones, supplying the energy so set free to the animal organism in the form of vital force. They may still have some food value, since they are not excreted as such, but undergo further simplification, till they appear as urea. It is certain that their food value (if any) is very much less than that of proteids proper. When once the urea stage is reached, the urea must be promptly got rid of. A form of blood poisoning known as uremia results when any obstruction to the elimination of urea occurs. . . .

“Apart from any possible nutritive value which they have, these flesh bases undoubtedly possess a stimulant action on the system, analogous to that exhibited by the alkaloids of tea, coffee, cocoa, etc., and it is beyond question that to this stimulating effect, rather than to any nutritive power, they owe their medical value.

“If, however, the beef tissues have been peptonized before extraction by water, the peptone formed will be taken into solution, along with the flesh bases, and the extract so formed will possess a true food value. Some manufacturers claim to peptonize the material from which they prepare their extract. This peptonization is not usually effected by means of pepsin, which would be too costly, but by acids, mineral or organic, or by vegetable ferments, such as that present in pineapple juice.

“Another way of introducing into the article true proteid material is to add finely ground ‘beef meal’ to the extract proper. Of course, such proteid matter is insoluble, and requires to be digested in the stomach before it becomes available for the repair of tissue waste. It does not properly form a part of the real extract, but has been added to this, in order to furnish a food value, which the true extract is known not to possess. No special value can be claimed for the ground beef so added over an equivalent weight of ordinary lean beef, except such as may accrue from the fact of its being in very fine powder, and thus more easily acted on by the digestive fluids of the stomach.”

Composition and digestibility of corn fodder and corn stover, C. G. HOPKINS (*Illinois Sta. Bul. 58, pp. 361-370*).—Continuing previous work (E. S. R., 8, p. 509), the digestibility of corn fodder and corn-and-cob meal was tested with 4 lots of 2-year-old steers, each lot containing 4 animals. In general the methods previously described were followed. To secure more uniform material for feeding and for analysis, the ears were separated from the stover, the stover was run through a cutting machine, and the corn and cobs were ground. The experiments covered 10 days, the results being reported for the first 4 days, the last 6 days, and for the whole period, to permit a study of

the effect of the length of period on digestibility. The average results follow:

Coefficients of digestibility of corn fodder and corn stover.

	Dry matter.	Protein.	Fat.	Carbohy- drates.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Corn fodder = ground corn and cobs and shredded stover, fed 4 days.....	68.3	43.3	68.2	74.8	68.7	23.9
Corn fodder, fed 6 days.....	67.0	43.3	64.0	73.5	67.0	23.1
Corn fodder, fed 10 days.....	67.5	43.3	65.7	74.0	67.7	23.4
Shredded corn stover, fed 4 days.....	58.1	37.8	58.9	60.5	69.9	23.0
Shredded corn stover, fed 6 days.....	58.3	37.1	52.6	60.7	70.5	22.2
Shredded corn stover, fed 10 days.....	58.2	37.4	55.2	60.6	70.3	22.5

The author's conclusions follow:

"When the ears are ground to corn-and-cob meal, corn fodder shows a higher percentage of digestibility than any other common coarse food stuff, the digestibility of the dry matter being 8 per cent higher than timothy hay and 14 per cent higher than clover hay. The total digestibility of corn fodder is increased 6 per cent by grinding the ears to corn-and-cob meal previous to feeding, while the value of the ears alone is increased nearly 20 per cent by grinding. In both its composition and digestibility corn stover closely resembles timothy hay, and the edible portion of the stover has a nutritive value fully equal to that of timothy."

Bullock feeding experiments in Norfolk, T. B. WOOD (*Jour. Bul. Agr.* [London], 6 (1899), No. 3, pp. 311-332).—In the first test reported, which was made in 1895-96, with 20 3-year-old Irish steers divided into 4 uniform lots of 5 each, the special object was to determine the amount of roots which could be profitably fed. After a preliminary period of about a month, the test proper began, November 28, 1895, and continued 77 days. All the steers were fed 10 lbs. per head of a grain ration made up of equal parts of linseed meal, cotton-seed meal, crushed wheat, and crushed barley. Hay and chaffed straw were fed *ad libitum*, and the following amounts of Swedish turnips: Lot 1 42 lbs. per head daily, lot 2 84 lbs., lot 3 126 lbs. (only 107 lbs. being consumed, on an average), and lot 4 all they would eat, averaging 115 lbs. per head.

The steers weighed on an average 1,254 lbs. at the beginning of the test. The average daily gains for the 4 lots were 1.8, 2, 2, and 2.2 lbs. per head, respectively. It was calculated that lot 1 converted 6.9 per cent of the dry matter consumed into beef; lot 2, 7.5 per cent; lot 3, 7.1 per cent, and lot 4, 7.6 per cent. At current prices for feeding stuffs, the profits on the 4 lots are calculated at \$15.35, \$18.23, \$15.13, and \$17.63, respectively. "The Norfolk practice of giving bullocks all the roots they will eat appears, therefore, to be an economical one, as it leads to a larger consumption of dry matter, a high percentage of which is converted into beef."

The comparative value of different commercial feeding stuffs was tested in 1896-97, 1897-98, 1898-99. The first of these tests was begun with 4 lots of 5 Irish steers, but one animal in each lot was dropped

on account of illness. The other two tests were each made with 4 lots of 5 each. Irish steers being used in 1897-98 and red polled Norfolks in 1898-99. The lots in every case were numbered from 1 to 4 consecutively. Each year lot 1 was fed linseed cake alone and lot 2 a mixture of equal parts of linseed cake and ordinary cotton-seed cake. Lot 3 was fed decorticated cotton-seed cake and maize meal (1:1) in 1896-97; in the other 2 tests dried brewers' grains was substituted for maize meal. Lot 4 was fed a mixture which through the greater part of the first test consisted of linseed cake, cotton-seed cake, maize meal, and dried grains. In the latter part of the test the dried grains was omitted. In the second test the grain mixture consisted of equal parts of linseed cake, cotton-seed cake, and maize meal; and throughout the greater part of the third test, of linseed cake and cotton-seed cake (1:1:1:1), linseed cake being used alone in the latter part of the test. The average daily gain made in the 3 years by the lots numbered 1 was 1.94 lbs.; by those numbered 2, 1.68 lbs.; and by those numbered 3, 1.61 lbs., the gain per hundred pounds of dry matter consumed being 7.04, 6.08, 5.8 lbs., respectively. The average daily gains made by the lots numbered 4 in the 3 years were 1.91, 1.53, and 1.41 lbs., respectively. "From the point of view, therefore, of the absolute increase produced by the feeding, linseed cake alone, as an addition to the usual Norfolk diet of chaff and roots, has shown in each of 3 years a decided advantage over each of the mixtures which have been tried."

A discussion of financial returns of the experiment, however, in the author's opinion, showed that at present prices a mixture of decorticated cotton-seed cake and some less expensive material, such as dried grains or maize meal, is more economical than linseed cake alone. "We must therefore add to the general conclusions that while linseed cake alone, and decorticated cotton-seed cake as part of a mixture, have given good results when fed to bullocks, the use of common cotton-seed cake has been throughout the experiment most unprofitable."

The live and dressed weight of the steers is recorded and the ratio of the latter to the former, the average of the 3 years for the lots numbered 1 being 59.1 per cent; the lots numbered 2, 57.99 per cent; the lots numbered 3, 58.69 per cent; and the lots numbered 4, 59.46 per cent. "[The steers fed linseed cake], which have made the greatest increase in weight, also give the highest proportion of carcass weight, while those which received common cotton cake are lowest both in rate of increase and percentage of carcass weight, the decorticated cotton cake lot coming midway in both cases."

Heavy, medium, and light meal rations for fattening steers, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 75, 76*).—In continuation of previous work (E. S. R., 11, p. 664), 3 lots of 3 steers each were fed for 168 days, beginning December 6, on different amounts of corn and oats, equal parts. The aim was to feed lot 1 a

pound of this mixture; lot 2, $\frac{2}{3}$ lb., and lot 3, $\frac{1}{3}$ lb. per 100 lbs. live weight at the start, and to increase this as rapidly as was deemed advisable. Lot 1 would not eat all the desired quantity, but was kept as near the limit as was deemed safe. All the lots were fed hay and pulped roots in addition to the grain.

The average daily gain of the 3 lots was 1.77, 1.74, and 1.62 lbs., respectively, the corresponding cost of food per pound of gain being 7.68, 7.22, and 7.21 cts. These results and those of previous tests are briefly discussed.

Feeding experiments with steers to compare Liebig's meat meal and cotton-seed meal, F. ALBERT (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 963-972).—The comparative value of meat meal and cotton-seed meal was tested with 2 lots of 7 steers each at the Lauchstädt Experiment Station. Lot 1 was fed, per 1,000 kg. live weight, 50 kg. of ensiled beet leaves, 2 kg. of meadow hay, 12 kg. of straw and chaff, 4 kg. of palm-cake molasses, 2 kg. of meat meal, and 7.59 kg. of ground corn. This furnished 3 kg. of digestible protein and 17 kg. of digestible nitrogen-free material. Lot 2 was fed the same ration except that 3.772 kg. of cotton-seed meal was substituted for the meat meal, and the ground corn was diminished to 5.899 kg. This furnished the same amount of digestible protein and nitrogen-free material as the ration fed lot 1.

During the test the amount of ensiled beet leaves was diminished to 30 kg., and 20 kg. of beet chips was added to the ration of each lot, more meadow hay and some alfalfa hay being fed also.

During the 154 days of the test, lot 1 made a total gain of 1,064 kg.; lot 2, 1,029 kg. The steers were slaughtered and judged by an expert. The conclusion was drawn that the meat meal used was a suitable feeding stuff and without bad effects on the condition of the steers or the dressed carcasses. The author also reports some figures regarding the loss which steers suffer in transportation and the length of time required to make good such losses.

Experiments in sheep feeding, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 82, 83).—Continuing previous work (E. S. R., 11, p. 666), a test of 42 days' duration is reported of the value of first and second cuttings of alfalfa and red clover for lambs.

"Everything considered, it can not be said that either of the fodders showed marked superiority over the other. The experiments indicate that the feeding values of red clover and alfalfa hay are very similar. All animals continued in perfect health from the beginning to the end of each experiment, indicating that alfalfa hay is a safe fodder for sheep, if it is cut and cured at the right stage of growth, say in early bloom."

A test is also briefly reported in which corn and peas were compared as food for fattening lambs. Three equal lots were used. Lot 1 was fed ground corn; lot 2, ground peas; and lot 3, a mixture of equal

parts of these grains. In every case a pound of meal per lamb was fed at the beginning of the test, the amount being increased until it reached $1\frac{1}{2}$ lbs. The test covered 104 days. The average weekly gain of the lambs in lot 1 was 2.52 lbs., 3.8 lbs. of meal being consumed per pound of gain. The lambs in lot 2 made an average weekly gain of 2.91 lbs., 3.3 lbs. of meal being consumed per pound of gain. The average weekly gain of the lambs in lot 3 was 2.6 lbs., the meal consumed per pound of gain being 3.68 lbs. "According to the results of the second trial, if pea meal is valued at \$20 per ton, ground corn would be worth \$17.35 per ton."

Sugar-beet pulp for sheep, H. C. PRICE (*Breeders' Gaz.*, 36 (1899), pp. 844, 855; *Agr. Student*, 6 (1900), No. 6, pp. 111-113).—A comparison of sugar-beet pulp with other feeding stuffs for sheep is briefly reported. The work was carried on at Cornell University. Four lots of 10 sheep each were used. Lot 1 was fed clover hay, lot 2 corn silage, lot 3 oat straw, and lot 4 sugar-beet pulp, enough grain being given in each case to make the nutritive ratio of the different rations the same. The conclusions reached follow:

"Sugar-beet pulp may be successfully fed to fatten sheep at the rate of 12 to 15 lbs. a day per head. At \$1 per ton it is a cheaper food for fattening sheep than corn silage at \$3 or clover hay at \$8 per ton. It can not become a stock food of importance outside of a radius of a few miles from the sugar-beet factory until some means is invented for expressing the water out of it. The best results can be obtained in fattening sheep on sugar-beet pulp and corn silage when some hay is fed with them."

Experiments with pure-bred swine, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 77-79, figs. 7).—Continuing previous work (*E. S. R.*, 11, p. 668), corn and barley were compared on 6 lots of pure-bred swine. The test is briefly reported. The food required per pound of gain in the different lots was as follows: Berkshire, 3.18 lbs.; Tamworth, 3.31 lbs.; Yorkshire, 3.35 lbs.; Chester White, 3.37 lbs.; Duroc Jersey, 3.37 lbs.; Poland China, 3.50 lbs. At the close of the test the pigs were slaughtered.

"In each of 4 experiments the Yorkshires and Tamworths were pronounced by the packers more suitable for the export bacon trade than the representatives of other breeds. Generally speaking, the results of 4 experiments indicate that economy of production is more dependent upon the individuality of animals than upon their breed. The experiments indicate that it does not necessarily cost more to produce a pound of gain upon a hog of suitable bacon type than upon a hog of undesirable bacon type."

Experiments with grade swine, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 80-82).—The value of different rations, as shown by the gains made and firmness of bacon produced, was tested with 4 lots of grade pigs, weighing about 60 lbs. each. Corn, peas, and barley were each fed alone and with middlings. The experiment lasted from July 28 to October 10, and included 49 pigs. At the close

of the test the pigs were slaughtered and judged by an expert. The author's conclusions follow:

"Exclusive corn feeding during a somewhat extended period gave very unsatisfactory results in point of gain, and produced bacon of extremely soft, undesirable character. The exclusive feeding of pea meal resulted in unthrifty animals and poor gains; but a mixture of 3 parts pea meal and 1 part middlings by weight gave good gains and produced bacon of excellent quality. An exclusive ration of barley gave satisfactory gains and produced exceptionally firm bacon. A two-thirds ration of barley with all the rape the hogs would eat, followed by about 3 weeks' exclusive barley feeding at the close, gave economical gains on the whole and produced bacon of good quality, though scarcely so firm as that produced by barley or by peas and middlings.

"Barley appears to be an exceptionally safe and valuable food for swine, whether fed alone or in combination with other foods. Peas should always be fed in combination with other foods, in which case they give good results. Exclusive corn feeding is no doubt risky under any conditions, but the practice can not be too strongly condemned when followed for any considerable length of time."

Fattening hogs with drought-resisting crops, H. M. COTTRELL and J. G. HANEY (*Kansas Sta. Bul.* 95, pp. 69-95, figs. 10).—Eight series of feeding experiments with pigs are reported on the value of crops which resist drought and are adapted to the Kansas uplands. These include Kaffir corn, soy beans, and alfalfa. Corn meal, cottonseed meal, and skim milk were fed in addition in some of the tests. Pure-bred Berkshire and Poland China pigs were used in the first 3 series, and in the remainder, cross-bred pigs, mostly Berkshire-Poland Chinas of average quality. Series 1 to 6 were made in the winter, series 7 in the spring, and series 8 in the fall and winter. Care was taken in each case to insure uniform lots. In the second series the pigs were fed in closed sheds. In the other series they were fed in the winter in sheds open to the south and in the summer had access to low sheds without sides. All the lots were given salt, wood ashes, and charcoal. The tests which had to do with soy beans were briefly reported in a previous publication (E. S. R., 12, p. 142).

The results of the different series are given in full in tabular form and are discussed in detail. General deductions are drawn from the work as a whole. Among the more important are the following:

"[The fact that] average mixed-bred hogs require from 10 to 30 per cent more food per hundred pounds of gain than the pure-bred hogs is a strong argument for better breeding. . . . The hogs that made the best gains in these experiments were well boned, with both fore and hind quarters well developed, rather rangy, well developed through the heart, with heavy-boned legs of fair length. The average amount of feed required to produce 1 lb. of gain was 5.28 lbs. of grain, with variations in feed ranging from 3.69 to 7.49 lbs. of grain. It is noticeable that the hogs requiring the least amount of feed per pound of gain had soy-bean meal in their rations. The 6 lots of hogs having soy beans as part of their ration required an average of 4.11 lbs. of grain per pound of gain, while the 19 lots not fed soy beans required an average of 5.64 lbs. of feed per pound of gain, an increase in food required of over 37 per cent. The moral of this is, raise and feed soy beans. Skim milk and alfalfa hay also greatly reduced the amount of grain required per pound of gain.

"Grinding Kafir corn gave greatest returns in our first experiment, showing a saving of 13 per cent in amount of feed required per pound of gain. In all other trials Kafir corn meal gave less gains than the whole grain, the loss from grinding being 9 and 14 per cent in the different trials.

"Soaking the Kafir corn resulted in losses of 7 and 17 per cent. Wetting the grain at the time of feeding gave best results, and this is the method we recommend. We put the whole grain dry into the trough and pour over it sufficient water or skim milk to thoroughly wet the grain. When water is used we add enough to have a little left in the trough after the grain is eaten. Kafir corn is dusty, and when fed dry makes hogs cough. Grinding alfalfa hay resulted in a loss, and we recommend the hay to be fed whole, just as to cattle. Grinding the soy beans caused a loss of 11 per cent in the one experiment where both ground and whole beans were fed.

"These experiments show that Kafir corn and either soy beans or alfalfa, properly combined, produce good results in fattening hogs. On an upland farm an acre of Kafir corn will produce more pork than an acre of corn. Kafir corn fed alone to hogs does not give nearly so large gains as when fed with soy beans or alfalfa hay. Kafir corn combined with either soy beans or alfalfa hay will produce more pounds of pork per acre from upland than are usually produced from adjoining bottom lands from corn. Kafir corn, or its near relatives, rice corn and Jerusalem corn, yield well in every part of the State. The experiments reported in this bulletin show that, by combining soy beans or alfalfa hay with Kafir corn, hogs may be fattened profitably on every farm in the State. Corn should be raised where it will yield more than Kafir corn, and Kafir corn where its yield is the higher. . . .

"The yields we have obtained from Kafir corn, soy beans, and alfalfa hay, the showing of only one crop failure in 11 years, and the good results obtained from fattening hogs with combinations of these feeds show a greater certainty of crop and more pounds of pork per acre than are usually secured by ordinary feeds in other States."

Report of the manager of the poultry department, W. R. GRAMHAM (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 130-134, fig. 1*).—Brief statements are made on the work of the poultry department during the past year. The points touched on are summer layers, early winter layers, feeding, artificial incubation, artificial *v.* natural incubation, egg preservation, raising ducks, fattening chickens, and cramming machine.

The different methods of preserving eggs tested were (1) immersion in solutions of water-glass of different strengths, (2) in lime solution, (3) coating with vaseline, (4) packing in common salt, (5) packing in dry oats, and (6) immersing in water-glass and packing in an egg case after drying. The author did not obtain as favorable results with solutions of water-glass as other investigators have. The eggs preserved in limewater had a slight taste of lime. Those coated with vaseline kept well, but absorbed a very undesirable flavor of the vaseline. Only a small percentage of the eggs packed in salt were bad, but all had suffered a good deal from evaporation. The eggs packed in oats were musty and had evaporated fully as much as those packed in salt. Those coated with pure water-glass were fairly well preserved, but lacked flavor.

The comparative value of skim milk and boiling water for moisten-

ing food was tested with 2 lots, containing respectively 6 and 7 Pekin ducks. Lot 1 was fed shorts, bran, and corn meal, 1:1:1, moistened with skim milk. Lot 2 was fed the same mixture, moistened with boiling water. After the first week a little animal meal was added to the ration of this lot. The lot fed skim milk made the better gain in 6 weeks. In 4 weeks following, when all had the skim-milk ration, the gains were the same for both lots. "It would appear that there is no advantage in mixing the food with boiling water."

Brief statements are made concerning the food eaten and gains made by 115 chickens fattened in coops. In 38 days the chickens consumed a total of 910 lbs. of oats, 305 lbs. of buckwheat, 900 lbs. of skim milk, and 9 lbs. of tallow, and made a total gain in weight of 216 lbs.

The possibility of influencing the color of dressed chickens by the ration fed was tested with 2 lots, each containing 3 Plymouth Rock pullets from the same hatching. Lot 1 was fed a mixture of finely ground oats and buckwheat, moistened with skim milk, and lot 2, yellow corn moistened with water. After 11 days they were killed and dressed. "Those on the oat and skim-milk ration presented a creamy-white appearance, while those fed on the yellow corn were of a deep yellow color."

What to eat and why, W. O. ATWATER (*Sci. Siftings*, 17 (1900), Nos. 436, p. 273; 437, p. 286; 438, pp. 300, 301; 439, p. 315; 440, p. 329; 441, p. 343; 442, pp. 356, 357; 18 (1900), Nos. 443, p. 7; 444, pp. 20, 21; 445, p. 35).—Reprinted from Farmers' Bulletin 23 of U. S. Department of Agriculture (E. S. R., 6, p. 752).

Banana or plantain flour (*Indian Forester*, 26 (1900), No. 3, pp. 90-92).—From articles in *Belgique Coloniale* and *Revue des Cultures Coloniales*, the composition of unripe and ripe plantain is quoted, the food value of the fruit is discussed, and directions given for a number of dishes made from plantain flour. Two analyses of banana flour are also quoted. (The term banana and plantain seem to be used interchangeably.)

Tolokno, a useful food, W. F. WELJAMOWITSCH (*Wojenno Med. Jour.*, 77 (1899), p. 1277; *Chem. Ztg.*, 23 (1899), No. 29, *Repert.*, p. 314).—Tolokno is a food product much used in northern Russia and other parts of the Empire. It is made by soaking oats for a day in water, heating them in an oven for a day, and then drying and removing the hull.

Value of gluten in flour, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 40, 41).—The author discusses briefly the importance of gluten from the standpoint of baking quality of flour, the influence of climate and soil on the character of the wheat, etc.

Analyses of cocoa, J. HUGHES (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 5, pp. 288-290).—Analyses of a number of brands of cocoa are quoted from the Ceylon *Tropical Agriculturist*.

Contribution to the chemical examination of tea, A. BEYTHIEN, P. BOHRISCH, and J. DEITER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 3 (1900), No. 3, pp. 145-153).—The author reports analyses of a number of sorts of tea.

Feeding stuff inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 59, pp. 22).—The points of the Maine law regarding the sale of feeding stuffs which the authors consider of most interest to the dealer and consumer are noted, and analyses

made in accordance with the law are reported of cotton-seed meals, gluten meals and gluten feeds of different brands, calf meal, linseed-oil meal of different brands, corn-and-oat feed of different brands, corn, oats, and barley; cereal by-products, poultry feed, rice feed, poultry meal, beefs craps, meat meals, and cattle or poultry bone. The constituents reported are protein and fat. The violations of the State law are discussed.

Feeding stuffs, H. B. McDONNELL (*Maryland Agr. Col. Quart.*, 1900, No. 8, pp. 1-14).—Theories of nutrition and other general matters are discussed, and the State law regarding feeding stuffs quoted. A number of analyses, made in accordance with this law, are reported, including corn, oats, and barley; cereal by-products, ground rye, corn meal, ground corn-and-cob meal, corn chops, fine siftings from ground corn, and a commercial mixed feed.

Fodders and feeds, L. A. VOORHEES and J. P. STREET (*New Jersey Stat. Rpt.* 1899, pp. 120-125).—Analyses are reported of oats and peas, cowpeas, soy beans, velvet beans, barnyard millet, pearl millet, crimson clover, sand vetch, green rye, green barley, corn fodder, teosinte, leaming corn, red and white Kafir corn, flint corn, rural branching durra, Southern white corn, evergreen broom corn, yellow millo maize, sugar cane, alfalfa (different cuttings), Dwarf Essex rape, hay, clover hay (second crop), gluten meal, cotton-seed meal, dried brewers' grains, dairy feeds, corn feed, wheat bran, wheat bran mixed with palm oil, grain hulls, mill sweepings, and beef meal.

Miscellaneous cattle-food analyses, W. FREAR (*Pennsylvania Sta. Bul.* 50, pp. 7-12).—Analyses are reported of cereal by-products, corn-oat-and-barley feed, buckwheat feed, buckwheat bran, buckwheat hulls, dried brewers' grains, cerealine feed No. 2, yellow dent corn, corn meal, ground corncobs, corn feed, adulterated cotton-seed meal, gluten feed and meal—misbranded, kiln-dried feed, wheat bran, and a condimental food.

Feeding and feeding stuffs, H. J. WHEELER and A. W. BOSWORTH (*Rhode Island Sta. Bul.* 64, pp. 103-124).—The authors discuss feeding stuffs and feeding standards and give a brief table showing the digestible nutrients in the principal feeding stuffs. The protein and fat in a number of samples of concentrated feeding stuffs sold in Rhode Island are reported, and when such data were available, the results compared with the manufacturers' guaranty of the composition of the feeding stuffs. The materials examined include cotton-seed meal, gluten meal, barley sprouts, corn-oat-and-barley feed, hominy feeds, cereal by-products, commercial mixed feed, and provender.

Condimental stock foods, R. W. CLOTHIER (*Industrialist*, 26 (1900), No. 34, pp. 457-461).—The composition of condimental stock food is reported and compared with other feeding stuffs. A lot of 211 sheep fed alfalfa hay and ear corn gained 117 lbs. more than a lot of 209 fed the same ration and condimental stock food in addition.

Distillery waste, W. FREAR and C. A. BROWNE (*Pennsylvania Sta. Bul.* 50, pp. 3-6).—The authors report the composition of distillery waste obtained in the manufacture of vinegar from fermented grain. In preparing this product for market the greater part of the water is removed from the material, which is finally pressed and dried. The sample analyzed represented the drained residue before drying.

Market prices of commercial feeds, L. A. VOORHEES and J. P. STREET (*New Jersey Stat. Rpt.* 1899, pp. 126, 127).—The market prices for several years of a considerable number of commercial feeding stuffs are reported.

Table of nutritive equivalents of different feeding stuffs, L. GRANDEAU (*J. Engrais*, 15 (1900), No. 3, pp. 65, 66).—A condensation of an article previously noted (*E. S. R.*, 12, p. 80).

Pie melons for stock feed, M. E. JAFFA (*Pacific Rural Press*, 59 (1900), No. 17, p. 261).—An analysis is reported.

Feeding value of beet tops and beet pulp (*Pacific Rural Press*, 59 (1900), No. 8, pp. 117, 118).—The comparative value of beets and other feeds is discussed.

Cattle feeding in the United States with residuum beet pulps and molasses (*Sugar Beet*, 21 (1900), No. 1, pp. 8, 9).—A brief account of the successful use of sugar beet by-products as feeding stuffs.

Use and abuse of rations, A. M. SOULE (*Tennessee Sta. Rpt.* 1899, pp. 31-33).—Brief popular notes are given on this subject.

Investigations on the behavior of animal food in the human body, K. MICKO, P. MÜLLER, H. PODA, and W. PRAUSNITZ (*Ztschr. Biol.*, 39 (1900), No. 2, pp. 277, 278).—A note on a series of investigations of which the following is the first.

Concerning plasmon, a new protein preparation, H. PODA and W. PRAUSNITZ (*Ztschr. Biol.*, 39 (1900), No. 2, pp. 279-312).—A full account of experiments briefly reported elsewhere.¹ Plasmon, a preparation made from the casein of skim milk was consumed as part of a mixed diet by several men. The digestibility of the ration was determined and the balance of income and outgo of nitrogen. The principal conclusions follow: Plasmon is well assimilated. Only very small amounts are excreted in the feces. As shown by the balance of income and outgo of nitrogen, plasmon can replace meat in the diet.

Comparative studies of the feces from plasmon and meat diet, K. MICKO (*Ztschr. Biol.*, 39 (1900), No. 3, pp. 430-450).—Continuing the work reported above, the author studied the feces when plasmon and meat were consumed, special attention being given to determining the ratio of nitrogen to phosphorus, the xanthin-nitrogen and nuclein bodies, casein, and paranuclein.

In the author's opinion the investigation showed that there was no appreciable quantity of undigested plasmon or its phosphorus compounds, casein or paranuclein, in the feces from plasmon. It was apparently completely digested, surpassing meat in this respect.

On the metabolism of matter in the living body, E. B. ROSA (*Phys. Rev.*, 10 (1900), No. 3, pp. 129-150).—A method for computing the balance of income and outgo of oxygen and hydrogen from the data usually recorded in experiments with the respiration calorimeter is described. The author believes such calculations are useful and that the weight of the subject should be determined at short intervals and this and other data used as a check on the accuracy of the work.

Farm superintendence, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, pp. 83-86, fig. 1).—Brief notes are given on farm superintendence; cattle, sheep, and swine kept at the station; methods of feeding; and the financial affairs of the agricultural college.

White cattle: An inquiry into their origin and history, R. H. WALLACE (*Reprint from Trans. Nat. Hist. Soc. Glasgow, n. ser.*, 5 (1897-1899), Nos. 2, pp. 220-273, figs. 32, pls. 7; 3, pp. 403-457).—A large amount of historical and other data leads the author to the conclusion that the white breed, commonly called Park Cattle, and White Cattle, are descendants of domesticated cattle which became feral many generations ago. Scotland is regarded as the source of the present English herds of white cattle. The origin of the Scotch herds is not definitely settled. The present publication is regarded as an introductory. An extended bibliography of the subject is given.

Heavy, medium, and light meal rations for fattening steers, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Bul.* 110, pp. 1-4).—Noted from other publications (E. S. R., 10, p. 277; 11, p. 664; 12, p. 372).

Pasteurized v. raw skim milk for calves, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt.* 1899, p. 67).—A brief account of a test in continuation of previous work (E. S. R., 11, p. 666). The total gain in 4 weeks of 4 calves fed pasteurized skim

¹ München Med. Wehnschr., 46 (1899), No. 26.

milk as part of a ration was 110 lbs. and of 4 calves fed raw skim milk under similar experimental conditions was 105 lbs.

Sheep, hogs, and horses in the Pacific Northwest, J. WITHEYCOMBE, H. T. FRENCH, and S. B. NELSON (*U. S. Dept. Agr., Farmers' Bul. 117, pp. 28, figs. 2*).—*Sheep husbandry*, J. Withycombe (pp. 5-16).—The author discusses sheep husbandry in the Pacific Northwest and in western Oregon with special reference to different forage crops, methods of feeding, pasturage, etc. The management of breeding ewes and lambs is also spoken of.

Hog raising in the Northwest, H. T. French (pp. 16-23).—Among the points treated of are breeds and breeding, quality of product, and feeds and feeding stuffs. In the author's opinion, hogs in the Northwest are generally very free from disease.

The horse industry of the Northwest, S. B. Nelson (pp. 23-27).—The horse industry of the past decade is reviewed and the effects on the industry of new inventions discussed as well as the present and prospective demand and the home market.

Alfalfa and red clover hay for lambs, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Bul. 110, pp. 6, 7*).—Summarized from earlier publications (*E. S. R.*, 11, p. 600; 12, p. 373).

Corn v. peas for fattening lambs, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Bul. 110, pp. 7, 8*).—Summarized from earlier publications (*E. S. R.*, 11, p. 667; 12, p. 373).

The Belgian hare, C. C. CHAPMAN (*Pacific Rural Press, 59 (1900), No 3, p. 38*).

DAIRYING—DAIRY FARMING.

A study of dairy cows, C. L. BEACH (*Connecticut Storrs Sta. Bul. 20, pp. 40, figs. 16*).—In order to get some idea of the average production of dairy cows in Connecticut the author collected data during the summer of 1899 as to the production of a number of herds supplying one of the large creameries in the State. A summary of the results showed an average annual yield of butter of 199 lbs. for 392 cows representing 47 herds. Only 9 herds, comprising 68 cows, averaged over 250 lbs. per year. Estimates by the author, based on records of the college herd, show that under conditions existing in the State cows yielding less than 250 lbs. of butter per year are not kept at a profit.

The author discusses variations in the production of individual cows, using illustrations from the records of the college herd, and gives suggestions for increasing the average production and for judging dairy cows.

A tabulated record of the college herd for 1898 is given showing the cost of food and the amount and value of milk and butter produced by each cow with the corresponding profit or loss. The principal facts presented in the record are summarized. The average yield per cow was 5,653 lbs. of milk and 313 lbs. of butter. The best butter cow produced 509 lbs. of butter, at a profit of \$42.82 over cost of food, and the poorest cow 172 lbs., at a loss of \$4.09. The two most profitable cows for butter were also the most profitable cows for milk. Of the 4 cows in the herd producing butter at a loss, 3 were registered cows of the dairy breeds.

The anatomical and physiological features of the dairy cow are discussed at some length.

A comparative study was made of individual cows as regards type and economy of production. In most cases 2 cows of the same breed representing different types were compared. Illustrated descriptions are given of 12 of the cows of the herd, with deductions from their records. The whole herd was divided into three groups corresponding to the following types: (1) Dairy type, cows spare in form with deep bodies; (2) beef type, cows with large frames and having a tendency to lay on flesh easily; and (3) cows lacking in depth and width of body. The following table summarizes the record of the college herd grouped according to types and breeds:

Average record of cows of different types and breeds.

	Number of cows.	Cost of food.	Amount of milk produced.	Cost of 100 lbs. milk.	Amount of butter produced.	Cost of 1 lb. butter.	Profit from milk at \$1.00 per 100 lbs.	Profit from butter at 18c. per lb.
		Dollars.	Pounds.	Cents.	Pounds.	Cents.	Dollars.	Dollars.
Types:								
Dairy	16	41.66	6,190	69	351	12.0	20.24	21.49
Lacking depth	5	39.83	5,322	77	267	14.9	13.40	8.36
Beef	4	38.59	3,916	100	217	18.1	.56	.55
Breed:								
Jersey	4	43.35	5,981	75	371	12.1	16.46	23.47
Grades	14	39.99	5,323	76	314	13.2	15.20	16.46
Guernseys	3	41.40	5,140	83	293	14.3	10.00	11.45
Ayrshires	1	40.65	6,166	69	266	16.0	21.01	7.32
Average of herd	25	40.80	5,653	76	313	13.6	15.72	15.51

"The record shows that in our herd the dairy type is nearly equal to the Jersey and excels the other breeds in production of butter. The dairy type is equal to the Ayrshires and excels the other breeds in the production of milk. On the whole the comparison seems to show that, under the present conditions, the type of the cow is more essential than the breed as indicating the ability to produce milk and butter economically."

Exercise for cows, B. TORSSELL (*Meddel. K. Landtbr. Sty.* 1900, No. 63, pp. 170-172).—Ten cows were separated into two even lots, one of which (lot A) was kept in the stable, while the other (lot B) was driven about 3.5 kilometers back and forth daily for 10 days. After 10 days the second lot was kept in, while the other one was exercised in the same way as lot B in the first period. The average yield and fat content of milk during a preliminary period of 3 days and during the experiment proper are shown in the following table:

Milk production with and without exercise.

	Preliminary.		With exercise.		Without exercise.	
	Milk.	Fat.	Milk.	Fat.	Milk.	Fat.
	Liters.	Per cent.	Liters.	Per cent.	Liters.	Per cent.
Lot A, 5 cows	63.47	3.48	59.29	3.60	57.91	3.42
Lot B, 5 cows	58.33	3.46	59.13	3.72	54.87	3.48
Total	121.80	3.47	118.42	3.66	112.78	3.45

In the author's opinion the conclusion seems warranted that the possible lower production obtained by giving the cows exercise in winter is more than compensated for by the favorable influence of this practice on the health and the hardiness of the cows.—F. W. WOLL.

Dairy husbandry, C. B. LANE (*New Jersey Stas. Rpt. 1899*, pp. 189–196, 202–269, *pl. 1, dgm. 1*).—Deductions from the results of dairy experiments previously reported (E. S. R., 11, p. 883) are quoted, and a detailed account is given of dairy work during the year.

Soiling crops (pp. 192–196).—Tabulated data, including dates of sowing and cutting, yield, and cost of production, are given for a long list of forage crops grown for the dairy herd. Brief notes are also given on the culture and growth of the different crops.

Experiments with different rations (pp. 202–220).—Seven tests of 14 days each and 2 tests of 7 days each were made with 2 cows to study the influence of rations varying widely in character, upon the yield and composition of milk and the economic production of milk and butter. The nine rations compared included the following feeding stuffs in various combinations: Wheat bran, dried brewers' grains, linseed meal, oats, cornstalks, hay, silage, green clover, and sugar beets. The nutritive ratios of the different rations varied from 1:4 to 1:14. The highest yield of milk and fat was produced on a ration having a nutritive ratio of 1:6.5, and the lowest yield on a ration having a ratio of 1:14. With one exception, changing from a wide to a narrower ration increased the yield of milk and fat, and changing from a narrow to a wider ration decreased the yield. A diagram shows the yield and composition of the milk of the cows on the changing rations as compared with like data for cows in the same stage of lactation fed uniformly during the same period. The fat content of the milk during the different periods ranged from 3.66 to 4.26 per cent. Tabulated data in regard to the economy of milk and butter production on the different rations show a net gain over cost of food of 32.9 per cent greater on well-balanced rations than on poorly balanced rations. The results of the study are summarized as follows:

“(1) The feeding of irregular rations caused a wide variation in the yield of milk and fat, and had a tendency to decrease the total yield.

“(2) The feeding of rations varying widely in respect to character and percentage of coarse foods, and amount of different food compounds and total nutrients furnished, had but little influence upon the composition of the milk.

“(3) Milk and butter were produced more economically from well-balanced rations than from rations containing a sufficient quantity of nutrients, but not in the proper proportion.”

An experiment with 4 cows comparing a “good” (balanced) and a “poor” (unbalanced) ration was made in continuation of a similar experiment already reported (E. S. R., 11, p. 884). The same cows and practically the same rations were used as in the earlier experiment.

The feeding periods in the present case were shortened to 15 days. On the balanced ration 15.1 per cent more milk and 21.9 percent more fat was produced than on the unbalanced ration. The gain over cost of food, however, was not marked. "As pointed out in the discussion of the previous experiment, the advantage of the good and more expensive ration is a larger production from the same number of animals, and thus a reduction in the capital required."

The yield and composition of milk obtained when the intervals between milkings are unequal and when they are equal (pp. 220-257).—Seven-day tests of 31 Holstein cows supervised by the station are reported by J. G. Lipman, and the detailed data are summarized to show the average weekly variations in the fat content of the milk of individual cows, proportionate yields of milk and fat at 3 daily milkings at unequal intervals, average yields of milk and fat per hour for the unequal periods between milkings, and the average fat content of the milk of the cows grouped according to age. Some of the author's deductions from the study follow:

"The difference between the highest and lowest daily average per cent of fat for any 7 consecutive days is under normal conditions usually less than 0.45 per cent. . . .

"When the intervals between milkings are unequal, there is a tendency to produce proportionately more fat after the shortest interval.

"When the intervals between milkings are unequal, there is a tendency for stalled cows to give proportionately more milk at the morning's milking.

"When the intervals between the two afternoon milkings are equal, the yields of milk are practically the same, but the yield of fat for the noon milking is greater.

"When the cows are on pasture, and the periods between milkings unequal, there is a tendency to yield more milk, in proportion, at the noon milking."

The average fat content of the milk of 6 cows, 2 years old, was 3.33 per cent; 6 cows, 3 years old, 3.62 per cent; 8 cows, 4 years old, 3.23 per cent, and 11 full-aged cows, 3.26 per cent.

In 2 experiments at the station to determine at what period of the day the most milk and fat are produced and the highest and lowest percentage of fat found, 4 cows were milked at 5 a. m. and 5 p. m., and 5 cows were milked at 5 a. m., 1 p. m., and 9 p. m. In another experiment to compare milking cows two and three times a day 4 cows were milked at equal intervals twice a day during the first and third periods and three times a day during the second period. Complete data for the 3 experiments are tabulated and the following summary is given:

"When the cows were milked at equal intervals twice daily, 51.9 per cent of the total milk was produced in the morning, and 41.8 per cent at night. Of the total fat, 50.6 per cent was produced in the morning and 49.4 at night. Of the 76 tests for percentage of fat, 59, or over three-fourths, were highest at night.

"When the cows were milked at equal intervals, three times daily, 36 per cent of the total milk was produced at 5 a. m., 32.8 per cent at 1 p. m. and 31.2 per cent at 9 p. m. Of the total fat, 33.3 per cent was produced at 5 a. m., 35.1 per cent at 1 p. m. and 31.6 per cent at 9 p. m. The highest percentage of fat occurred at

1 p. m., or the period nearest the noon hour, and the lowest percentage in the morning.

"When 4 cows were changed from twice to three times milking, they gained 3.03 per cent in yield of milk and 0.78 per cent in yield of fat. The average per cent of fat decreased 0.09.

"When 4 cows were changed from three times milking to twice, they decreased 10.3 per cent in yield of milk and 9.4 per cent in yield of fat, and the average per cent of fat increased 0.04.

"The results of milking three times daily indicate that a third milking will not pay as a regular farm practice."

Cost of producing milk (pp. 257-260).—The cost of the milk production of the herd is given for the year ended April 1, 1899. The data contained in the present report, as well as similar data for the two preceding years, were summarized in the bulletin of the station previously referred to.

Soiling crop rotation (pp. 261, 262).—A table gives the total yield and amount of nutrients obtained per acre from the various combinations of soiling crops grown during the year. A continuous supply of forage was furnished the dairy herd from May 1 to November 1.

Dairying in relation to soil exhaustion (pp. 263, 264).—The amount of fertilizing elements contained in the feeding stuffs purchased and in the milk produced by the station herd for 3 years is given in tabular form. The results show a decided gain to the farm in fertilizing elements.

Record of the dairy herd (pp. 264-269).—A record of 12 cows is given for the year ended April 1, 1899. The principal results are summarized in the following table:

Records of best and poorest cows for milk and butter production.

	Annual yield.	Value of product.			Cost of feed.	Gain over cost of feed with—		
		Milk at 1 ct. per lb.	Milk at 3 cts. per qt.	Butter at 20 cts per lb.		Milk at 1 ct. per lb.	Milk at 3 cts. per qt.	Butter at 20 cts. per lb.
		<i>Pounds.</i>						
Milk production:								
Best cow	10,169	\$101.69	\$139.95	\$46.32	\$55.37	\$93.63
Poorest cow	5,090	50.90	70.05	46.32	4.58	23.73
Average cow	6,965	69.65	95.85	46.32	23.33	49.53
Butter production:								
Best cow	484	\$96.80	46.32	\$50.48
Poorest cow	247	49.40	46.32	3.08
Average cow	318	63.60	46.32	17.28

The average waste for 3 years in handling, cooling, bottling, and delivering milk was 9 per cent.

Report of the professor of dairy husbandry, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 54-74*).—Notes are given on the work of the dairy school during the year, and various experiments, partly in continuation of previous work (E. S. R., 11, pp. 681, 683), are reported.

Care of milk for cheese making (pp. 55-58).—Experiments were con-

ducted during the summer to study the effect of different methods of treatment on the sweetness of milk and on the quality of curd and cheese. During the hot weather aeration alone was not found sufficient to keep milk sweet over night and in good condition for cheese making the following morning. A small quantity of ice in a can set in the milk was more effective than aeration. Milking and aerating in the stable or pasture did not seem to affect the occurrence of gassy curds, nor did the rejection of the first milk drawn prevent this trouble. "A good flavored starter in the milk seems to be the best remedy for gassy and other bad flavors. . . . When the cows are healthy and are fed on clean food and are milked in a cleanly manner, in a clean place, aeration is probably of no particular advantage to milk for cheese-making."

During July and August several experiments were made to determine to what temperature milk should be cooled on Saturday evening in order to have it in good condition on Monday morning. The results indicated that during the summer milk should be cooled to 58 to 60°, and in hot weather to 50 to 55° in order to keep it sweet over Sunday.

Careful v. rough handling of curd (pp. 58, 59).—In each of 3 tests, 1,200 lbs. of milk was divided into 2 equal lots and treated alike, except that one lot was handled very roughly at cutting and during heating, while the other lot was handled as carefully as possible. Careful handling increased the yield of cheese. The quality was practically the same in each case.

Curing cheese at different temperatures (pp. 59–61).—Cheese made at the college and at 2 factories was cured at temperatures of about 60, 65, and 70°. Cheese cured at 60° lost about one-half per cent less in weight than cheese cured at 70°, and was also better in quality. The results were the same with cheeses weighing 30 and 75 to 80 lbs. In 11 experiments cheese cured at 69° for one week and then finished at 60 or 65° was compared with cheese cured at 60, 65, and 69° for the whole time. The results indicated no advantage in curing at high temperatures for a week. The cheese cured at 60° scored the highest.

A bad flavor in cheese (pp. 61, 62).—Notes are given on the occurrence of a bad flavor in curd and cheese in a large number of factories, and a method for treating the curd to overcome the difficulty is quoted.

Methods of controlling temperature in cheese-curing rooms during hot weather (pp. 62–65).—Notes are given on the construction and cost of subearth ducts in a number of factories visited by the author. The use of water, fans, and compressed air for cooling curing rooms is also briefly discussed.

Effect of pasture on the fat content of milk (pp. 65, 66).—The average fat content of the milk of the dairy herd for 17 days before the cows were turned out to pasture was 3.69 per cent in the morning and 3.8

per cent in the evening. For the first 17 days on pasture the average fat content of the morning's milk was 4.36 per cent, and of the evening milk 4.47 per cent. The results agree with those previously obtained.

Changes in colostrum milk during 21 milkings (p. 66).—Determinations with the Quevenne lactometer and Babcock test were made of the milk of 5 cows for the first 21 milkings after calving. The addition of sulphuric acid to the first and second milkings gave a decided purple tinge to the precipitate. This is suggested as a method for detecting colostrum milk. The data for the tests are tabulated and summarized as follows:

"There was a gradual decrease in the percentage of fat and the percentage of solids-not-fat with three cows, and a decrease of the solids-not-fat in the milk of all five cows from the first to the twenty-first milking. In the case of one cow, an Ayrshire grade, the percentage of fat increased from the first to the twenty-first milking, while another grade Ayrshire was lower in fat for the first eight milkings, then increased, and afterwards decreased.

"Milk is not normal until the eighth or ninth milking after calving, and in some cases the twelfth or fourteenth milking contains an abnormal proportion of solids-not-fat."

Dilution creamers or "separators" (pp. 67, 68).—Tests were made of the Hydro-lactic, Wheeler, and Brampton cans in comparison with the Cooley can. Milk was diluted one-half and set at room temperature in the Hydro-lactic, Wheeler, and Cooley cans. Undiluted milk was set in the Brampton and Cooley cans, which were kept in ice water. The results showed little or no advantage in the use of dilution creamers as compared with ordinary cans in which milk is set in ice water without dilution. Setting for but 3 to 4 hours in the dilution process, as recommended by the manufacturers of the dilution cans, was less satisfactory than setting for a longer time. The dilution process lowered the quality of the butter and lessened the value of the skim milk.

Ripening cream with different percentages of starter (p. 68).—The cream was ripened without the use of a starter as compared with the addition of 5, 15, and 20 per cent starter. "The starter caused the cream to ripen more quickly, but there was little or no difference in the quality of the butter. This agrees with the results obtained for the past two years."

Ripening cream at different temperatures (p. 69).—In each of 21 experiments made during July and August cream was divided into 2 lots, one of which was ripened at 70 to 75° and the other at 55 to 60°. The yield and quality of the butter favored ripening at the lower temperature, agreeing with results previously obtained.

Pasteurizing milk and cream for butter making (pp. 69–71).—Experiments were conducted during April and May to study the effect of pasteurization in butter making. The butter made in the experiments

was sent to two firms from which scorings were obtained. The results are summarized in part as follows:

"There was less loss of fat in the skim milk from pasteurizing the whole milk before separating.

"There was less volume of cream from pasteurized milk, but the cream was richer.

"By using a starter after cooling there was no difficulty in ripening the cream from pasteurized milk.

"The pasteurized cream churned in less time than the raw cream.

"The yield of butter per 1,000 lbs. of milk was 0.89 lb. greater from the unpasteurized milk. . . .

"All the trials indicated that butter from pasteurized milk had better keeping qualities, although when first made there was little or no difference in the quality. . . .

"Pasteurized skim milk kept sweet from 24 to 48 hours longer than the skim milk from the separator where the whole milk was not heated to 160°."

Mangels v. turnips fed to cows for butter making (p. 71).—Butter made from cows fed mangels scored 2.3 points higher than that from cows fed turnips.

The dairy herd (pp. 71, 72).—A tabulated record of the dairy herd of 23 cows for the year is given, with a summary of the principal data.

Milk tests at the fall fairs (p. 73).—Records of tests of 41 cows are tabulated.

Foreign coloring matter in milk, A. E. LEACH (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 4, pp. 207-210).—"Out of 23,098 samples of milk collected throughout the State [of Massachusetts] during 5 years (1894-1898) 151 samples, or 0.6 per cent, were found to contain foreign coloring matter. Of these samples about 88 per cent contained annatto, approximately 10 per cent were found with an aniline orange, and about 2 per cent with caramel. . . . About 95 per cent of the milks found colored in Massachusetts showed on analysis the fraudulent addition of water."

The method employed by the author for the examination of samples suspected of being colored is described in detail.

The ripening of cream, H. W. CONN (*Connecticut Storrs Sta. Bul.* 21, pp. 24).—This is a general discussion of the purposes, cause, and control of cream ripening; the effect of different species of bacteria; the use of pure cultures in the United States and Europe; results of the use of pure cultures; methods employed in the use of pure cultures; and the use of starters with and without pasteurization. The author's summary of the discussion follows:

"(1) The market price of butter depends in a large degree upon the character of the ripening of the cream.

"(2) The only method the butter maker has of controlling this ripening is by the use of 'starters,' followed by a maintenance of a proper temperature.

"(3) The most logical method of using these starters is first to pasteurize the cream and then inoculate it with a pure culture of a favorable species of bacteria. This method is almost universal in Denmark, but it produces very mild-flavored butter

and has not been extensively adopted elsewhere. It is better adapted to European taste than to the taste of lovers of butter in the United States.

“(4) The use of starters without pasteurization has been quite widely adopted in American creameries. This is a less logical method, but the results are satisfactory. The butter obtained is more highly flavored than that from pasteurized cream.

“(5) The starter used may be either a commercial starter or a natural starter. There is little to choose between them. The latter is more commonly used in the United States. The question whether the one or the other should be used is largely a matter of convenience.

“(6) The use of starters will not make good butter out of poor cream.”

Report of the bacteriological department, M. N. Ross (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 96-100, fig. 1*).—Mention is made of the distribution of starters among various butter and cheese makers, and brief notes are given on the use of starters.

Bacteriological examinations showed that cheese cured at a low temperature had a higher bacteria content during the first few days than cheese cured at a high temperature. Cheese made in the fall had a higher germ content than cheese made in the spring and summer. The superior flavor of cheese cured at a low temperature and also of fall cheese is therefore attributed to the increased number of bacteria present in such cheese. *Bacillus coli communis* thrived better in cheese cured at a low temperature, and liquefying bacteria grew better in cheese cured at a high temperature.

A species of *Torula* was isolated from samples of bitter cheese obtained from several factories. The characters of this organism are noted. This trouble which is known as “bitter milk” caused considerable loss to cheese makers of Ontario during the summer. Further investigations are necessary before suggestions for the exclusion of this germ from milk can be made.

Two samples of water used in factories where much trouble from gassy curd was experienced were examined. In each case a different species of gas-producing bacteria was isolated. A pure culture of lactic-acid germs was used with one of the gas-producing species with very beneficial results.

Practical hints for the dairyman, F. S. COOLEY (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 273-288*).—This treats of soiling crops for dairy cows, cow stables, selection and testing of cows, and the care of milk.

Dairying, W. R. SESSIONS (*Massachusetts State Bd. Agr. Rpt. 1899, pp. 45-73*).—A general discussion of the subject.

Dairy farming, A. M. SOULE (*Tennessee Sta. Rpt. 1899, pp. 25-28, figs. 3*).—A popular discussion on the selection, breeding, and testing of dairy cows, with suggestions for keeping a herd record.

Feeding the dairy cow, A. M. SOULE (*Tennessee Sta. Rpt. 1899, pp. 29-31, fig. 1*).—This discusses in a popular manner the composition of milk, general principles of feeding, and the relative value of pasture and soiling crops for milk production. Several rations for dairy cows are suggested.

Mangels v. sugar beets for milk production, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 76, 77*).—An experiment previously noted (*E. S. R.*, 11, p.

688) is summarized and a similar comparative test of mangels and sugar beets for milk production is reported. The experiment included 4 cows and lasted 4 weeks. "Everything considered, these experiments indicate that there is very little, if any, difference between mangels and sugar beets as foods for stimulating the flow of milk. It must be remembered, however, that these experiments have no bearing upon the relative value of these foods for maintaining life or producing fat."

Mangels v. sugar beets for milk production, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Bul. 110*, pp. 46).—An account is given of 2 comparative tests of mangels and sugar beets for milk production previously reported (*E. S. R.*, 11, p. 688; 12, p. 388).

Milking record experiment, J. A. MURRAY (*Ann. Rpt. Field Expts. Agr. Dept. Univ. Col. Wales, 1899*, pp. 26-30).—Records of 5 herds of 5 cows each for 3 months were obtained for the purpose of comparing Welsh Black and Shorthorn breeds of cattle for dairy purposes. The results, while not considered conclusive, showed a much larger yield of milk in favor of the Welsh Black breed.

Concerning the cows' milk in Varna, Bulgaria, C. STRYZOWSKI (*Oesterr. Chem. Ztg.*, 3 (1900), No. 7, pp. 157, 158).—The author reports analyses of 7 samples of milk. He states that nothing corresponding to a modern milk control exists in Bulgaria and the milk supply has been little studied. Where a control exists it usually consists in determining the specific gravity and testing for the presence of starch or brain matter, although adulterations of this kind are said to occur very rarely.

On the variability of the dry matter of milk and its value for judging market milk, A. REINSCH and H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 3 (1900), No. 8, pp. 521-531).

The value of a regulated milk control for cities, A. LAMB (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 3 (1900), No. 7, pp. 472-475, dgm. 1).

Milk and milk bacteria, S. SERKOWSKY (*Milch und ihre Bakterien*. Warsaw, 1900, pp. 129; rev. in *Ztschr. Untersuch. Nahr. u. Genussmtl.*, 3 (1900), No. 8, p. 591).

Lactic acid bacteria, M. E. McDONNELL (*Inaug. Diss.*, Kiel, 1899, pp. 60, pls. 3).—This contains the results of extended observations and investigations on the growth of lactic-acid bacteria in different media, milk fermentations, and the morphology and physiology of lactic-acid bacteria, and their maximum, minimum, and optimum temperatures. A classification is given of the different lactic-acid germs and the propagation of pure cultures for dairy purposes is considered.

The coagulation of milk by rennet, DUCLAUX (*Ind. Lait.*, 25 (1900), Nos. 30, pp. 233, 234; 31, pp. 241, 242; 32, pp. 249, 250).—The action of rennet on the different milk constituents is discussed.

Effect of sewage water on renneted milk, G. S. THOMSON (*Jour. Agr. and Ind. South Australia*, 3 (1900), No. 11, pp. 911-914, figs. 3).—Sewage water obtained from a drain running from a cheese-making room and added to pasteurized milk produced a stringy and gassy curd. This trouble was observed in 2 factories.

The effect of churning on fat globules, G. A. FLICKINGER (*Tennessee Sta. Rpt. 1899*, pp. 34-36, fig. 1).—A popular discussion.

The normal bacterial invasion of the cow's udder, V. A. MOORE (*Proc. Soc. Prom. Agr. Sci. 1899*, pp. 110-113).—The author calls attention to the bacterial invasion of the udder as one of the sources of milk contamination, basing his discussion of the subject mainly on investigations previously noted (*E. S. R.*, 10, p. 1094; 12, p. 184).

VETERINARY SCIENCE AND PRACTICE.

The problem of infection and immunity, A. D. PAWLOWSKY (*Ztschr. Hyg. u. Infektionskrankh.*, 33 (1900), No. 2, pp. 261-312).—In this article the author reports the results of extensive experiments

concerning the fate of pyogenic organisms in susceptible and immune animals. After organisms have come to be located in the hypodermal connective tissue, they are rapidly carried into the blood and internal organs. This is accomplished largely by means of the lymph currents. The observed microscopical facts in connection with this problem lend no aid to the theory that pathogenic organisms may be carried from the source of infection to other parts of the body through the agency of phagocytes. Many pathogenic organisms which have become located in the subcutaneous connective tissue are later excreted in the urine and bile. This excretion is occasionally very extensive. The early period of primary excretion of the pathogenic organisms is called by the author the elimination period of infection. A bibliography of 130 titles on the literature of the subject is appended to the article.

Report of the biologist, J. NELSON (*New Jersey Stas. Rpt. 1899, pp. 273-320, pls. 4*).—The author reports that among the college dairy herd as many abortions occurred during the year following the disinfection treatment as during the preceding year.

Details are given of a number of autopsies upon animals which had been condemned after receiving the tuberculin inoculation. The author gives a summary of observations extending over a period of 6 years upon the college dairy herd with reference to the extermination of tuberculosis in this herd. From observations made during this time, the author concludes that allowance should always be made for individual differences in the reaction to the tuberculin test; that, as a general theory, a resting period of several months should be allowed between any 2 tuberculin tests; and that the course of the disease does not seem to be affected by tuberculin injections, either by way of aggravation or alleviation of the disease. A general discussion is presented of the contagiousness of tuberculosis, on the curative action of tuberculin, on the advisability of a reinjection, the length of period between injections, the rapidity of development of tuberculosis, and the detection of tuberculosis by physical symptoms.

The author made a study of a bacteriological disease of ducks which resembled to some extent chicken cholera. An outbreak of this disease occurred in a flock of 100 ducks and as the death rate became large it was recommended that 1 per cent carbolic acid be given in the drinking water and that an astringent be given in soft feed. These remedies seemed to have a decidedly beneficial effect in checking the disease. The author made cultures of the micro-organism and inoculated one of the partly recovered ducks from the diseased flock. A mild attack of the disease followed this inoculation. The disease in question seemed to be confined largely to the small intestines. The liver appeared normal and the other *post-mortem* findings were not strictly like those of chicken cholera. Inoculations of pure cultures of the bacillus in guinea pigs were without result.

The author gives a detailed description of various bacteriological apparatus upon which improvements have been made, including a tube carrier for a hand centrifuge, a thermo-regulator, sterile pipette for plate cultures, and a test-tube holder. Notes are also given on the use of the platinum loop and on methods of detecting tubercle bacillus in tissues.

Results of the Lorenz method of inoculation against hog cholera with Prenzlau vaccine during the years 1897-1899, E. JOEST and A. HELFERS (*Berlin. Tierärztl. Wchnschr.*, 1900, No. 11, pp. 121-124).—The number of hogs inoculated was 217,376. In general the inoculations were endured by the hogs without any disturbance of the general health conditions. The number of deaths which were attributed to inoculation by this method was 40, of which 31 cases were not carefully investigated. One case showed necrosis of the cervical ligament, 3 erysipelas of the head, 1 peritonitis, 1 articular inflammation, and 2 gastro-enteritis. The number of cases of hog cholera which developed in consequence of the injection of cultures was 202. In these cases the disease was manifested within from 2 to 7 days after the inoculation. Sixty-four of these cases recovered spontaneously. The inoculation failed to produce a sufficiently complete immunity in 155 cases which became later infected with the natural disease. The question whether inoculated hogs transmit the disease to uninoculated hogs was answered in the negative in nearly all the reports. Of the hogs which were suffering with hog cholera, 68.8 per cent were cured by the method.

Partial paralysis and crippling of swine, J. H. REED and G. E. DAY (*Ontario Agr. Col. and Expt. Farm Bul.* 110, pp. 8-12).—During the winter and spring months many pigs become somewhat paralyzed or lame from an apparent rheumatic affection. In paralysis the appetite is variable and the hind limbs are so affected that locomotion is scarcely possible. In rheumatic affections the symptoms are similar to those of paralysis, with the exception that the joints are frequently swollen and sensitive. This form of paralysis is usually the result of digestive disturbances associated with constipation. These digestive troubles are due to overfeeding or improper feeding and lack of exercise. The rheumatic troubles are mostly caused by improper buildings, poor ventilation, or damp sleeping places.

The curative treatment for these affections consists largely in correcting these faults in diet or surroundings, the use of a tonic, such as nux vomica, and suitable purgatives. Under the head of "Correctives," the author refers to substances which are not strictly foods, but which assist in bringing about a normal digestive action. Among these substances may be mentioned fresh earth, ashes, and charcoal. Suggestions are given as to proper plans for building the piggery, so that damp floors may be avoided and proper ventilation secured.

Toxicological experiments with nitrate of strychnine upon geese, ducks, chickens, and pigeons, J. SCHNEIDER (*Monatsh. Prakt. Thierh.*, 11 (1900), No. 6, pp. 245-269).—The experiments reported upon in this paper included hypodermic injections of strychnine in the breasts of domesticated birds and the feeding of strychnine by way of the mouth. The general results obtained from these experiments may be tabulated as follows:

Dose of strychnine per kilogram live weight.

	Given hypodermically.		Given by way of mouth.	
	Therapeutic dose.	Minimum lethal dose.	Therapeutic dose.	Minimum lethal dose.
	Mg.	Mg.	Mg.	Mg.
Geese	0.4	1.0	0.6	2.5
Ducks	0.5- .6	0.1-1.1	1.5-2.0	3.0-4.5
Chickens	1.0	3.0	2.0-3.0	30.0
Pigeons5- .75	1.0	6.0	8.5

From these data it appears that pigeons are least susceptible to internal doses of strychnine so long as the experiments are confined to therapeutic doses, while chickens manifest the greatest resisting power against lethal doses. The experimental birds which were killed, whether by internal or hypodermic doses of strychnine, were cooked and eaten without experiencing any peculiarity in the taste of the meat or any effects from the strychnine.

Handbook of meat inspection for veterinarians, physicians, and judges, R. OSTERTAG (*Handbuch der Fleischbeschau für Tierärzte, Ärzte und Richter.* Stuttgart: Ferdinand Enke, 1899, 3. ed., pp. 902, figs. 251, pl. 1).—This book is a general treatise on the subject of meat inspection, and contains discussions of the following related matters: Government regulations of the sale of meat, inspection of animals before slaughter, inspection of carcasses, the normal appearance of various organs, abnormal physiological conditions, general pathology of slaughtered animals from the health officers' standpoint, organic diseases of special importance, anomalies of the blood, cases of poisoning, animal parasites, plant parasites, slaughter for acute infectious diseases, *post-mortem* changes in meat, coloring and inflation of meat, preservation of meat, boiling, and steam sterilization.

The taking of samples for trichina inspection, C. NOACK (*Deut. Thierärztl. Wchnschr.*, 8 (1900), No. 8, pp. 66, 67).—Detailed directions for the selection of samples from meat to be inspected in order that the inspection may give reliable results.

The examination of condemned meat, H. L. ELLERMAN (*Tijdschr. Veeartsenijk en Verzett.*, 27 (1900), No. 2, pp. 99-126).—A detailed account of the methods of inspecting meat for the presence of various diseases.

The meat inspection law of the United States, A. MÖLLER (*Ztschr. Fleisch u. Milchhyg.*, 10 (1900), No. 6, pp. 101-106).—A critical examination of the law of this country concerning meat inspection.

The treatment of acute muscular rheumatism with acetanilid, E. ZINCKE (*Deut. Thierärztl. Wchnschr.*, 8 (1900), No. 8, pp. 65, 66).—This article discusses the symptoms of muscular rheumatism and reports the successful use of acetanilid in treating it.

The determination of the value of tetanus antitoxin and its use in human and veterinary medicine, E. BEHRING (*Deut. Med. Wchnschr.*, 26 (1900), No. 2, pp. 29-32).—The author states that in order that tetanus antitoxin may be fairly tested it is necessary that treatment with it shall be begun not later than 30 hours after the appearance of tetanus symptoms. Intravenous injection is recommended in the place of hypodermic.

Pathogenesis of local lesions of infectious origin, M. DE VIEDMA (*Gac. Med. Vet.*, Madrid, 24 (1900), No. 159, pp. 101-104).—A brief study of croupous and diphtheritic membranes, gangrene, and tuberculosis.

The cocco-bacillus of Pfeiffer, G. ROSENTHAL (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 11, pp. 266-268).—Experiments were tried with this organism in association with other organisms of variable virulence. Mice inoculated with a mixture of pneumococcus and this cocco-bacillus died of septicæmia. Rabbits inoculated in the lung with a mixture of cocco-bacillus and an old culture of staphylococcus succumbed to pulmonary congestion in the course of a few days.

The bacillus of Koch in the milk of human tubercular patients, H. ROGER and M. GARNIER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 8, pp. 175-177).—The tubercle bacillus was found in the milk of a tuberculous woman although there was no evidence of mammary lesions. The author calls attention to the bearing of this observation upon the question of the infectiousness of cows' milk.

Serum diagnosis of tuberculosis, E. BENDIX (*Deut. Med. Wchnschr.*, 26 (1900), No. 14, pp. 224, 225).—Brief notes on the results obtained by the application of this method to cases of tuberculosis of man.

The effect of different medicaments in the treatment of experimental tuberculosis, J. HÉRICOURT and C. RICHER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 12, pp. 275-278).—The authors conducted numerous experiments in inoculating dogs with tuberculosis and in testing the therapeutic value of various medical agents. During these experiments it was found that all such agents which were tried had a greater or less effect in checking the progress of the disease. Among the substances which were used, the following may be mentioned: Common salt, urate of sodium, aristol, creosote, camphor, Liebig's extract of beef, bichlorid of mercury, iodine, terebinthine, lead, and thallium.

The present status of tuberculin injection, with special reference to practical experiments with this substance, OSTERTAG (*Ztschr. Fleisch u. Milchhyg.*, 10 (1900), No. 7, pp. 121-130).—The author discusses the literature of the subject with reference to actual practical results which have thus far been obtained in different countries in combating tuberculosis by means of tuberculin.

Attention is called to the importance of destroying all animals in which clinical evidence of tuberculosis can be seen, and especially cows with chronic cough, chronic diarrhea, and tuberculosis of the udder. The author believes that all dangerous tuberculous animals may be destroyed and that by the aid of tuberculin herds of cattle may be reared which are entirely free from tuberculosis.

The influence of oxygen under pressure on Koch's bacillus in liquid cultures, F. ARLOING (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 12, pp. 291, 292).—Oxygen under pressure of from $1\frac{1}{2}$ to $2\frac{1}{2}$ atmospheres exercises a very marked restraining influence upon the development of Koch's bacillus in liquid media. The length of time seems to be more important than the intensity of the pressure. The influence of oxygen under pressure was sufficient to destroy completely the virulence of cultures of the tubercle bacillus as shown by subsequent experiments in inoculating rabbits.

The treatment of tuberculosis in the nineteenth century, BÄUMLER (*Berlin. Klin. Wchnschr.*, 37 (1900), No. 14, pp. 293-298).—An account of the application of various surgical and medicinal treatments for tuberculosis, together with notes on the use of tuberculin for the diagnosis of the disease in its earlier stages.

Tuberculosis in man and cattle, J. LAW (*Country Gent.*, 65 (1900), No. 2457, pp. 176, 177).—A controversial article in which arguments are presented to prove the identity of human and bovine tuberculosis.

Prevention of bovine tuberculosis, E. NOCARD (*Jour. Agr. [Paris]*, 11 (1900), No. 120, pp. 56-59).—A general discussion of the regulations which have been found most effective in controlling this disease.

An experiment in producing immunity against foot-and-mouth disease by feeding cooked milk from diseased animals, SCHMIDT (*Hessische Landw. Ztschr.*, 70 (1900), No. 9, pp. 108, 109).—The author conducted experiments during which 10 pregnant cows were fed with cooked milk from other animals which were suffering from foot-and-mouth disease. Each cow received 2 liters of such milk a day, which had been cooked for a quarter of an hour. None of these cows contracted the disease although they were thoroughly exposed to infection.

An attempt to produce immunity against foot-and-mouth disease by feeding cooked milk from diseased animals, SCHMIDT (*Berlin. Tierärztl. Wchnschr.*, 1900, No. 8, pp. 86, 87).—The author states that he has recommended this method to stock owners and farmers in producing immunity against foot-and-mouth disease. It was observed that calves and pigs were rendered immune against the disease by this method. Ten cows received daily 2 liters of milk from cows which had had severe attacks of the disease. The milk was cooked for 15 minutes. The cows were much exposed to the disease but none of them contracted it.

Spaying cows, J. WESTER (*Tijdschr. Veeartsenijk en Veeveelt*, 27 (1900), No. 2, pp. 127-162).—This article contains an elaborate discussion of the spaying methods which have been proposed by different authors, and a bibliography of the subject is appended.

Milk fever, W. O. ROBERTSON (*Vet. Jour.*, 50 (1900), No. 298, pp. 183-189).—A general discussion of the symptoms, etiology, and treatment of this disease.

The etiology of parturient paresis, W. A. THOMAS (*Amer. Vet. Rev.*, 23 (1900), No. 11, pp. 798, 799).—The lesions of this disease are said to be in the brain and spinal column.

Parturient fever, H. S. SMITH (*Amer. Vet. Rev.*, 23 (1900), No. 10, pp. 702-708).—The author maintains that this disease is not due to disturbances of metabolic processes in the udder alone, but is due to general autointoxication. In the treatment of cases of parturient fever, the author used iodid of potash by way of mouth and not as injections in the udder. Good results were obtained by this method, and the author suggests that hypodermic injections of iodid of potash might also give good results.

General observations on the method of adherence of cestodes to the intestinal wall, P. MINGAZZINI (*Extr. Arch. Ital. Biol.*, 32 (1899), No. 3, pp. 12, figs. 6).—From a study of microscopic sections of the scolex of cestodes attached to the intestinal walls, the author presents a detailed account of the exact manner of such attachment.

Parasitological notes, B. GALLI-VALERIO (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 9, pp. 305-309, figs. 4).—An account of an epizootic disease of laboratory guinea pigs caused by *Trichomonas carie*.

Poisoning with *Agrostemma githago*, K. KRONACHER (*Wchnschr. Tierheilk. u. Viehzucht*, 44 (1900), No. 12, pp. 109-115).—The author discusses the clinical symptoms of 5 cows which were supposed to have been poisoned by this plant. From a study of these cases, the author came to the conclusion that the seeds of this plant, which were fed along with other material, had been crushed and that therefore the saponin contained in them came in contact with the mucus lining of the stomach and alimentary tract.

Pathological-anatomical conditions in poisoning by ricin, F. MÜLLER (*Beitr. Path. Anat. u. Allg. Path.*, 27 (1900), No. 2, pp. 331-348, pl. 1).—Samples of the blood

of experimental animals were drawn about 14 hours after giving a lethal dose of ricin. Immediate changes were found to have been produced in the relative proportion of the small lymphocytes, the large lymphocytes with round nuclei, polynuclear cells, and eosinophilous cells. The marrow of hollow bones, the liver, and kidneys were also examined under the microscope, and detailed descriptions are given of the changes in their microscopic structure under the influence of ricin poisoning.

Treatment of infectious diarrhea of calves with tannoform, SCHÜNHOF (Berlin. Tierärztl. Wchnschr., 1900, No. 14, pp. 101, 102).—The author reports that a treatment of young calves with calomel and tannoform gave good results in preventing the appearance of this disease.

Husk or hoose in calves, M. J. CLEARY (Irish Agr. Organization Soc. Leaflet 9, p. 1).—An account of the etiology and treatment of verminous bronchitis.

Public inoculation against hog cholera in Würtemberg, REINHARDT (Deut. Thierärztl. Wchnschr., 8 (1900), No. 13, pp. 109, 110).—A statistical account of the number of animals inoculated, the quantity of inoculation material used for each animal, and the price charged for the operation.

The preparation of a swine-plague serum, W. NIEBEL (Deut. Thierärztl. Wchnschr., 8 (1900), No. 10, p. 83).

Hydrophobia in the horse, C. W. EDDY (Agr. Student, 6 (1900), No. 6, pp. 113-115).—Brief notes on the symptoms of this disease.

Rabies in the District of Columbia, D. E. SALMON (U. S. Dept. Agr., Bureau of Animal Industry Circ. 30, pp. 15).—A controversial article in reply to certain criticisms upon the action of the Commissioners of the District of Columbia in issuing a muzzling order to prevent the spread of rabies. The circular is for the most part occupied in establishing the proposition that rabies is a real disease.

The clinical diagnosis of rabies, PETER (Berlin. Tierärztl. Wchnschr., 1900, No. 12, pp. 133-136).—A report of detailed observations on the relative frequency and value of various clinical symptoms in the diagnosis of rabies.

The lesions of rabies in dogs and post-mortem diagnosis of this disease, G. HEBRANT (Ann. Med. Vet., 49 (1900), No. 2, pp. 76-81).—The most constant lesions of this disease in dogs are found in the peripheral cerebro-spinal and sympathetic ganglia, and consist in an atrophy, invasion, destruction of the nerve cells, and formation of neomorph cells which appear between the nerve cells and their epithelial capsule.

Fowl cholera, H. DE COURCY (Irish Agr. Organization Soc. Leaflet 7, p. 1).—Popular notes on the nature and treatment of this disease.

Concerning diphtheria of birds, P. CAGNY (Rec. Med. Vet., Paris, 8. ser., 7 (1900), No. 4, pp. 83-85).—Brief notes on the relationship between fowl diphtheria and diphtheria of man.

Report of the bacteriological department, M. N. ROSS (Ontario Agr. Col. and Expt. Farm Rpt. 1899, pp. 93-96).—The author made a study of the roup of chickens. A number of experiments were conducted in inoculating chickens suffering from this disease with antidiphtheria serum. Only 1 chicken recovered as a result of the inoculation, and it was doubtful whether this recovery was due to the serum or to the good care given the fowls. The author reports a number of cases of mycosis in fowls, and discusses the nature, cause, and methods of treatment of this disease.

Regulations for the control of contagious diseases of live stock, C. CURTICE (North Carolina Dept. Agr., Biol. Div., 1900, pp. 32, map 1).—This pamphlet contains copies of the various regulations of the State regarding quarantine and the control of contagious diseases in live stock, together with suggestions regarding the burial of carcasses, the destruction of cattle ticks, and the treatment of tick fever.

AGRICULTURAL ENGINEERING.

A new dairy barn, A. M. SOULE (*Tennessee Sta. Rpt. 1899, pp. 9-18, figs. 11*).—A description, with drawings, is given of the barn completed at the station in the early part of 1899, at a cost of about \$5,000:

“The building is a frame structure 54 by 73 ft. 6 in., exclusive of the silos, which are 18 by 30 ft., and an annex which is 18 by 50 ft. . . . The silos are situated at the south end of the barn, some 10 ft. being under ground. This brings them on a level with the basement, and, as they open into the cow stable, it materially lessens the labor of feeding. . . .

“The annex on the west side of the barn is two stories high. In the basement are stalls for bulls and calves, while the upper story is devoted to the various wagons and implements needed in farm work. . . .

“The barn is built into the side of a small hill. By the construction of a retaining wall, which also forms the foundation of the two interior sills, and by projecting the barn forward on the face of the slope, a stable is secured opening on the ground level, and yet sufficiently protected on the north and west to keep it warm in winter. This leaves two faces of the stable foundation exposed, so that a continuous row of windows on the eastern and southern sides gives ample light and ventilation. This method of construction brings the second floor on a level with the ground, and no artificial bridges are necessary to enter the barn. . . .

“The roof is trussed from above so as to leave the storage space in the clear. . . .

“The factory system of exposed structural timbers was followed in the construction of the stable, and the spaces between the supporting timbers are inclosed with matched ceiling and the whole painted white. This gives an attractive appearance and permits the walls to be washed whenever necessary.

“The cow stable is situated in the basement, and is provided with a Portland cement floor, having a sloping surface. . . . The mangers face the exterior walls of the barn.”

The construction of the mangers and stalls is the same as in the Wisconsin Station barn (E. S. R., 11, p. 595), except that it has been found necessary for experimental purposes to provide divisions between the mangers.

“This has been cheaply accomplished by cutting out a section of board the shape of the manger, hinging it over the lower angle of the stall division with hoop iron, placing a 2 by 6 scantling at the near side of the manger, and fastening the division firmly by a sliding bolt lock. These partitions are so nicely adjusted that they prevent the admixture of the different cows' feed, and at the same time just sufficient space is left to enable the free movement of water through the entire length of the feeding trough. Their mobility and ease of adjustment is a decided advantage when it becomes necessary to scour the manger. Stalls are provided in the stable for 30 cows.

“The basement also contains a stock-judging room where specimens of the different classes of live stock are brought in and conveniently examined and scored by the agricultural students. . . . Box stalls are provided also in the basement for sick animals and for calves. Closets are conveniently placed for tools and other sundries needed in the stable. The milk room occupies the southeast corner, and is partitioned off from the main stable so that the milk can be immediately removed and kept where there is little danger of its being tainted. This room contains the aerator, milk scale, composite sample jars, tables, and other accessories needed for keeping the various records. The milk is immediately aerated and cooled after being drawn

from the cow, and removed from the building. In the summer time an electric fan is used to cool the milk.

"The feed room is provided . . . with scales and the necessary apparatus. . . .

"There are 3 silos, rectangular in form, with rounded corners, 10 by 18 ft. and 24 ft. high. Their combined capacity is between 250 and 300 tons. The first 10 ft. below the ground is constructed of brick and cement work. Above that point they are built of wood and painted with coal tar. . . .

"On the ground floor [of the barn] ample space is provided for storage. This part of the barn is arranged so that the teams can drive right through and dispose of their loads. . . . A tool room is conveniently located in one corner, and contiguous to this is a storage box for sawdust, which is used for bedding and is carried down to the stable by means of a chute.

"A large experimental seed room is on this floor, which contains the machinery for threshing the grains from the experimental plats, and also space for storing and sorting the same until such times as they may be needed for use. A loft is built above this room so that in case of bad weather the grains harvested from the plats can be drawn in and housed here until threshed. On this floor is located the cutting and grinding machinery, the thresher, and the motor for supplying power. The motor is so placed as to run the grinding and cutting machinery from the same position. The other machinery is driven by means of shafting."

Irrigation (*Tradesman*, 44 (1900), No. 2, p. 62).—This article calls attention to the growing importance of irrigation in the humid region and the need of the enactment of proper laws for the control of the public water supply in the humid as well as in the arid region.

The conquest of arid America, W. E. SMYTHE (*New York and London: Harper & Bros.*, 1900, pp. XVI+326, pls. 6, maps 3).—This book, by the editor of *Irrigation Age*, discusses the history, development, and present status of irrigation in the arid region of the United States from the economic standpoint, and is based upon materials "gathered by ten years of life, work, and study in various parts of the West." The first part of the book deals in a general way with the extent, characteristics, and possibilities under irrigation of the arid region; the second discusses the social and industrial development of the Mormon commonwealth in Utah, the Greeley Colony in Colorado, Southern California, and the irrigated portion of the Great Plains; the third discusses in some detail irrigation development in the several States of the arid region; the fourth treats of such economic questions as the surplus people and the means of colonizing them, and colony plans and institutions—their administration and adaptation to changing conditions. A brief note on methods of irrigation is given as an appendix.

The growth of irrigation in America, E. MEAD (*Irrig. Age*, 14 (1900), No. 11, pp. 376-385).

Irrigation in Idaho, W. FAWCETT (*Sci. Amer.*, 83 (1900), No. 10, p. 149, figs. 4).

Agriculture and irrigation in the Rio Grande Valley, C. W. KINDRICK (*Sci. Amer. Sup.*, 49 (1900), No. 1275, p. 20440).—A brief note.

Water supply and irrigation in Porto Rico, G. E. MITCHELL (*Irrig. Age*, 14 (1900), No. 10, pp. 346, 347).—A brief note.

Irrigation methods in China, G. E. MITCHELL (*Irrig. Age*, 14 (1900), No. 11, pp. 386, 387).

Australian irrigation farms (*Sci. Amer. Sup.*, 50 (1900), No. 1283, pp. 20561, 20562).—A description of government work in irrigation by artesian wells in New South Wales.

Water measurement and manipulation in Colorado, H. A. CRAFTS (*Sci. Amer.*, 83 (1900), No. 6, p. 85, figs. 3).—A description of methods and results of irrigation in the State.

The maximum duty of water. The extent to which tillage may take the place of irrigation, F. H. KING (*Irrig. Age*, 14 (1900), No. 4, pp. 127-137).—A paper read before a farmers' club in Kansas.

An irrigation plant in Provence, E. FARCY (*Jour. Agr. Prat.*, 1900, II, No. 32, pp. 206, 207, fig. 1).—A brief description is given of a plant in which water is raised from a stream to a height of 25 meters by means of a turbine and pump, the turbine being driven by water diverted from the stream by means of a barrage. The arrangement of canals, siphons, and reservoirs and the results obtained from irrigation are also noted.

The evolution of farm machines with some suggestions as to their use, G. P. SMITH (*Massachusetts State Bd. Agr. Rpt.* 1899, pp. 246-257).—This article discusses improvements made during the nineteenth century in plows, harrows, drills and planters, weeders and cultivators, and mowers and reapers.

A station for testing agricultural implements at Paris, A. DE CERIS (*Jour. Agr. Prat.*, 1900, I, No. 23, pp. 832-834, fig. 1).—Mainly lists of names of men who have taken part in the work of this station, which was founded in 1889, and of the various machines which have been tested there.

The construction of county roads and bridges, J. C. NAGLE (pp. 14).—An address prepared for the Good Roads Club of Brazos County, Texas, July 22, 1899.

STATISTICS—MISCELLANEOUS.

Twelfth Annual Report of Louisiana Stations, 1899 (*Louisiana Stas. Rpt.* 1899, pp. 16).—An account is given of the work at the Sugar Station at Audubon Park, the State Station at Baton Rouge, and the North Louisiana Station at Calhoun. The report also contains an outline of the report of the Geological Survey of Louisiana for 1899, notes on the soil survey of the State now in progress, the organization lists of the stations, and a financial statement for the fiscal year ended June 30, 1899.

Annual Report of New Jersey Stations, 1899 (*New Jersey Stas. Rpt.* 1899, pp. XIX + 512).—This includes the organization lists of the stations; financial statement of the State Station for the year ended October 31, 1899, and of the College Station for the fiscal year ended June 30, 1899; a report of the director reviewing the different lines of station work; and reports of the chemists, assistant in horticulture, assistant in dairy husbandry, biologist, botanist, and entomologist containing articles abstracted elsewhere.

Twelfth Annual Report of Tennessee Station, 1899 (*Tennessee Sta. Rpt.* 1899, pp. 80).—This includes the organization list of the station; a report on the staff and general work of the station, with a more detailed outline of the present and proposed work of the agricultural department; a financial statement for the fiscal year ended June 30, 1899; outline of a ten weeks' course in agriculture; a description of a new dairy barn; and miscellaneous articles abstracted elsewhere.

Report of the experiment station at Lyngby, Denmark, for 1898, K. HANSEN (*Tidsskr. Landbr. Planteavl*, 6 (1900), pp. 57-78).

Report of the experiment station at Tystofte, Denmark, for 1898, N. P. NIELSEN (*Tidsskr. Landbr. Planteavl*, 6 (1900), pp. 79-81).

Report of the experiment station at Askov, Denmark, for 1898, F. HANSEN (*Tidsskr. Landbr. Planteavl*, 6 (1900), pp. 82-96).

Report of the experiment station at Vester-Hassing (Knoldgaard), Denmark, for 1898, A. J. HANSEN (*Tidsskr. Landbr. Planteavl*, 6 (1900), pp. 97-109).

Crop Reporter (*U. S. Dept. Agr., Crop Reporter Vol. 2, Nos. 1-3, pp. 8 each*).—Beginning with No. 1 of the present volume this publication combines the monthly crop reports and a publication for the exclusive use of crop correspondents previously issued by the Division of Statistics of this Department. In addition to statistical

data on the condition of crops in the different States and Territories in May, June, and July, these numbers contain statistics and popular articles on a variety of subjects, such as New York State canals, agriculture in India, methods for estimating areas of land, sheep grazing on forest reserves, principal crops of Germany for the years 1893-1899, the distribution of the area of production, jute crop of India, the origin of seedless orange culture in the United States, the 1900 wheat crop of British India, and pear blight.

The cotton crop of 1898-99, J. L. WATKINS (*U. S. Dept. Agr., Division of Statistics Bul. 17, misc. ser., pp. 32*).—This contains statistical data on the cotton crop of the different States and Territories as shown by the movement of cotton from the plantation to points of export or consumption and also statistical information on cotton mills in the South and amounts of cotton purchased by them, the Sea Island cotton crop of 1898-99, the value of the cotton crop of 1898-99, comparative acreage and production, the cost of picking cotton, exports of cotton from United States ports, consumption of American cotton by foreign countries, the world's consumption of cotton, cotton acreage since 1894, and cotton crops since 1893. The total cotton crop for the year is estimated at 11,189,205 commercial bales, valued at \$305,467,041. Of this the Sea Island crop amounted to 67,791 bales valued at \$3,594,245.

The development of the American cotton industry, F. HART (*Jour. Franklin Inst., 150 (1900), No. 3, pp. 161-172*).

Cotton movement and fluctuations 1894 to 1899, LATHAM, ALEXANDER & Co. (*New York: 1899, pp. 151, figs. 6*).

The sugar industry and the manufacture of rum in Porto Rico, E. DELAFOND (*Sucr. Indig., 56 (1900), No. 2, pp. 40-42*).

Sugar industry of Porto Rico, E. DELAFOND (*Internat. Sugar Jour., 2 (1900), No. 20, pp. 432, 433*).—A discussion of the conditions and possible future of the production of cane sugar in Porto Rico.

The peanut-oil industry, R. P. SKINNER (*U. S. Consular Rpts., 63 (1900), No. 236, pp. 82-87*).—The manufacture of peanut oil in France is described and statistics are given concerning the source of the peanuts used for the purpose, their market value, etc.

Agricultural returns for Great Britain for 1899 (*London: Wyman & Sons, 1900, pp. XLVI + 261*).—This report shows the acreage and produce of crops, prices of grain, and number of live stock, with agricultural statistics for the United Kingdom, British possessions, and foreign countries.

Station publications (*Kansas Sta. Bul. 94, pp. 56-67*).—A complete list of station publications is given, those out of print being indicated. The principal subjects treated in the publications are indexed.

Finances—meteorology—index (*Maine Sta. Bul. 58, pp. 8 + 159-171*).—This was published as a part of the Annual Report of the station for 1899 (E. S. R., 12, p. 297).

German Agriculture at the end of the nineteenth century, WERNER and ALBERT (*Arb. Deut. Landw. Gesell., No. 51, pp. 96*).—This is a memoir written on the occasion of the World's Fair at Paris and summarizes the progress of German agriculture during the past 25 years along the following lines: Soil culture; agricultural chemistry; manuring; field crops, including rye, wheat, barley, oats, potatoes, legumes, sugar beets, fodder crops, and commercial crops; stock farming, dealing with horses, cattle, sheep, hogs, and goats; and technical agriculture, such as dairying, sugar-beet manufacture, manufacture of spirits and starch. A final chapter on the agriculture of Germany in the past, present, and future concludes the work.

The development of agricultural instruction in Germany and the seminary for agricultural teachers in the University of Leipsic, G. JOHN (*Fühling's Landw. Ztg., 49 (1900), Nos. 11, pp. 406-411; 12, pp. 445-449; 13, pp. 473-479*).

NOTES.

NEBRASKA STATION.—At a recent meeting of the board of regents, E. Benjamin Andrews, chancellor of the university, was appointed director of the station, and T. L. Lyon, who during the interregnum has been acting director of the station, was appointed associate director.

NEW HAMPSHIRE COLLEGE AND STATION.—Marion Imes, M. S., has been appointed instructor in veterinary medicine and assistant in dairy husbandry. Roscoe H. Shaw, assistant chemist, resigned September 15 to take a position in the Wisconsin University and Station. David B. Bartlett, B. S., has been appointed assistant in bacteriology.

OHIO STATION.—J. C. Burneson, V. S., has been appointed veterinarian of the station.

OKLAHOMA STATION.—At a recent meeting of the board of regents, A. B. McReynolds was appointed assistant in chemistry, *vice* A. G. Ford, resigned.

RHODE ISLAND STATION.—Cooper Curtice has been engaged as biologist, *vice* G. W. Field, resigned. The station has from time to time made exhibits of its products at the county fairs, in connection with the educational exhibits of the college, which have attracted considerable attention. Members of the station staff are preparing timely notes on the work of the station for local agricultural papers, and are making some little effort to visit farms in different sections with a view to getting into closer touch with the farmers and with their needs. There has been an unusual demand for the poultry publications of the station.

TENNESSEE STATION.—The agricultural department has recently prepared a permanent exhibit of the products of the station farm for the past year for the use of the Knoxville Chamber of Commerce, to be sent to the various farmers' meetings in the State to inform them in a graphic way of the lines of work conducted and the progress being made. It consists of twenty-five large, double, oak-framed cases that can be closed and locked and transported readily from place to place. This exhibit was prepared at a cost of about \$500, provided by the Knoxville Chamber of Commerce. Already it has done much good and has materially aided in drawing the attention of the farmers toward the station and its work. It has proven the most effective means yet found of demonstrating to the farmers the aid the station can be to them in their work.

TEXAS COLLEGE AND STATION.—J. W. Carson, who for some years was foreman of the farm, has been elected superintendent of the farm. A. M. Ferguson, assistant horticulturist, has resigned to accept the position of assistant botanist in the University of Texas.

UTAH STATION.—Ephraim G. Gowans, M. D., has been appointed biologist of the station, and B. K. Jones, assistant at the Massachusetts station, has been appointed assistant chemist.

VERMONT STATION.—A. W. Edson, A. B., has been appointed assistant botanist.

WISCONSIN UNIVERSITY AND STATION.—F. W. Woll, chemist, has been granted a year's leave of absence, which he will spend in study in Germany.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils, (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH and V. A. CLARK.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. 5.

	Page.
Editorial notes:	
Need of more perfect organization of the experiment stations.....	401
Differentiation of the investigator from the teacher	403
Fourteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations, E. W. Allen	404
Recent work in agricultural science.....	416
Notes.....	499

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

The relation of chemistry to the progress of agriculture, H. W. Wiley.....	418
The estimation of alumina and ferric oxid in natural phosphates, F. P. Veitch.....	416
A new method for the determination of aluminum, E. T. Allen and V. H. Gottschalk.....	416
Estimation of calcium carbonate in soil, H. Schütte.....	417
Direct estimation of calcium in the presence of iron and aluminum, L. Blum ..	417
Soil humus—some sources of error in analytical methods, A. L. Emery.....	417
Gypsum and limestone, G. W. Shaw.....	419

BOTANY.

Progress of plant breeding in the United States, H. J. Webber and E. A. Bessey ..	421
Progress of economic and scientific agrostology, F. Lamson-Scribner.....	421
Economic grasses, F. Lamson-Scribner.....	421
Report of the botanist, C. E. Bessey.....	419

	Page.
The accumulation of asparagin in legumes grown with insufficient light, E. Bréal	420
Concerning the pectic matter of plants, A. Hébert	420
On the hybrid fecundation of the endosperm of maize, H. de Vries	421
ZOOLOGY.	
Revision of American voles of the genus <i>Microtus</i> , V. Bailey	422
A review of economic ornithology in the United States, T. S. Palmer	423
METEOROLOGY—CLIMATOLOGY.	
Nile floods and monsoon rains	424
Work of the meteorologist for the benefit of agriculture, commerce, and navigation, F. H. Bigelow	424
Anemometer tests, C. F. Marvin	425
Meteorological tables, T. S. Outram	425
AIR—WATER—SOILS.	
Soil investigations in the United States, M. Whitney	426
A study of soil moisture, C. A. Keffer and J. D. Tinsley	425
Soil moisture, H. H. Nicholson	426
FERTILIZERS.	
Alfalfa as a fertilizer, B. C. Buffum	427
Nitrate of soda and sulphate of ammonia on marsh soils, Clausen	428
The basic constituents of crops, R. Warrington and E. Demoussy	428
Change in weight of some artificial fertilizers on exposure to the air, L. von Wissell	428
Analyses of commercial fertilizers, M. B. Hardin	430
Analyses of commercial fertilizers, J. L. Hills, C. H. Jones, and B. O. White	429
Commercial fertilizers, J. H. Stewart and B. H. Hite	430
FIELD CROPS.	
Report of the agriculturist, T. L. Lyon	430
Alfalfa as a hay crop, B. C. Buffum	430
Corn culture, C. W. Burkett	432
Report on tests of deep and shallow plowing for corn	442
Results of experiments on cotton in Alabama, P. H. Mell et al.	433
The southern or cow pea in Delaware, A. T. Neale and W. H. Bishop	435
A two years' test of 128 varieties of grasses and forage plants, T. L. Lyon	436
Rescue grass (<i>Bromus unioloides</i>), F. Lamson-Scribner	442
Analyses of forage crops, H. H. Nicholson	442
Succulent forage for the farm and dairy, T. A. Williams	442
The influence of chlorin and other compounds in crude Stassfurt salts on the composition and yield of potatoes, B. Sjollema	436
Sorghum for sirup, G. W. Shaw	443
Sugar-beet investigations in 1899, J. H. Stewart and B. H. Hite	437
Sugar cane—field and laboratory results for ten years, W. C. Stubbs	438
Work of the Hawaiian Experiment Station, 1899, W. Maxwell	440
Growth of the tobacco industry, M. Whitney and M. L. Floyd	443
HORTICULTURE.	
Report of the horticulturist, R. A. Emerson	449
Gardening under glass, W. F. Massey and A. Rhodes	444
Progress of commercial growing of plants under glass, B. T. Galloway	449

	Page.
Forced peas in pots, G. Wythes	444
Experiments with tomatoes and potatoes, F. W. Rane	449
Apple production in Virginia, W. B. Alwood	445
Growing strawberries in New England, F. W. Rane	450
Analyses of strawberries, G. W. Shaw	445
Investigation and improvement of American grapes at the Munson Experiment Grounds from 1876 to 1900, T. V. Munson	446

FORESTRY.

Progress of forestry in the United States, G. Pinchot	455
Forest reserves in the United States, H. Gannett	452
Practical tree planting in operation, J. W. Toumey	452
The practice of forestry by private owners, H. S. Graves	455
Pure woods or mixed woods, W. Schlich	453
Observations on the temperature, growth, and moisture content of various trees, W. R. Lazenby	453
The production of high-class oak, ash, and larch timber, W. Schlich	454

SEEDS—WEEDS.

Seed selling, seed growing, and seed testing, A. J. Pieters	458
Twenty-first annual report of the Swiss seed control station at Zurich, F. G. Stebler, E. Thielé, and A. Volkart	456
Effect of formaldehyde on the germination of cereals and on smut spores, S. David	457
Canada thistle, L. H. Dewey	458

DISEASES OF PLANTS.

Progress in the treatment of plant diseases in the United States, B. T. Galloway ..	460
The diseases of beet seeds and means for combating them, Linhart	458
Bacteriosis of beet roots, A. Stift	458
An inquiry into the cause and nature of crown gall, J. W. Toumey	458
Some citrus troubles, H. H. Hume	463
Stigmonose: A disease of carnations and other pinks, A. F. Woods	460

ENTOMOLOGY.

Progress in economic entomology in the United States, L. O. Howard	467
Report of the division of entomology, L. Bruner	468
Insect pests	465
Insect record for 1899, C. M. Weed	468
The sweet-potato weevil (<i>Cylas formicarius</i>), H. Tryon	465
Some scale insects upon Kansas grasses, E. A. Popenoe and P. J. Parrott	466
The forest tent caterpillar, C. M. Weed	466
Contribution toward a monograph of the American Aleurodidae, A. L. Quaintance	469
The red spiders of the United States, N. Banks	469
The crop pest law, W. B. Alwood	467
Spray calendar	470

FOODS—ANIMAL PRODUCTION.

Development of the nutrition investigations of the Department of Agriculture, A. C. True and R. D. Milner	476
Cost and composition of bread in Oregon, G. W. Shaw	476
The ideal ration for an army in the tropics, E. L. Munson	470

	Page.
The composition and physiological effects of beef broth, A. Gantier.....	470
A dietary study, G. W. Shaw.....	476
Baking powders, H. K. Miller.....	477
Cattle foods, G. W. Shaw.....	471
Cattle foods—miscellaneous analyses, H. H. Nicholson.....	478
Changes in the chemical composition of feeding stuffs during storage, H. Witt.....	471
Analyses of commercial feeding stuffs, J. L. Hills, C. H. Jones, and B. O. White.....	472
Skim-milk calves, H. M. Cottrell, D. H. Otis, and J. G. Haney.....	472
Feeding steers; feed value of cotton seed and its products, J. H. Connell and H. C. Kyle.....	473
Work of the breeders in improving live stock, J. Clay, jr.....	478
Pig feeding, J. S. Newman and J. S. Pickett.....	475

DAIRY FARMING—DAIRYING.

Dairy development in the United States, H. E. Alvord.....	484
Investigation in milk production, T. L. Haecker.....	479
Feeding dairy cows, T. L. Haecker.....	484
Dairy value of pea-vine silage compared with that of June pasture, A. T. Neale.....	481
On the influence of heredity on the quality of cow's milk, G. Cederholm.....	482
Galactase, E. von Freudenreich.....	484

VETERINARY SCIENCE AND PRACTICE.

Some examples of the development of knowledge concerning animal diseases, D. E. Salmon.....	488
Administrative work of the Federal Government in relation to the animal industry, G. F. Thompson.....	488
Report of the animal pathologist, A. T. Peters.....	488
Remarks on the epidemiology and prophylaxis of malaria in the light of recent researches, A. Celli.....	485
The fatal effect of green sorghum, R. S. Hiltner.....	486
Report on cooperative experiments in the treatment of hog cholera, A. T. Peters, C. M. Day, and C. H. Walker.....	487
Hog-cholera remedies, H. H. Nicholson.....	491
A note on serum diagnosis of glanders, Bourges and Méry.....	488

AGRICULTURAL ENGINEERING.

Irrigation and the <i>associations syndicales</i> , A. Chavard.....	492
Observations on Chavard's paper, P. P. Dehérain.....	492
Rise and future of irrigation in the United States, E. Mead.....	496
Experiments in grinding with small steel feed mills, F. H. King.....	492
Progress of road building in the United States, M. O. Eldridge.....	496
Silage and the construction of modern silos, F. H. King.....	495

STATISTICS—MISCELLANEOUS.

Annual Report of Minnesota Station, 1899.....	496
Thirteenth Annual Report of Nebraska Station, 1899.....	496
Agricultural experiment stations in the United States, A. C. True.....	497
Progress of agriculture in the United States, G. K. Holmes.....	497
Yearbook of the Department of Agriculture, 1899.....	497
Proceedings of the Agricultural Students' Association, 1899-1900.....	497

EXPERIMENT STATION RECORD.

VOL. XII.

No. 5.

Much attention has been given during the past year to questions relating to the more perfect organization of the experiment stations. As the stations develop, the importance of a clearer definition of the functions of different officers in administration and investigation becomes more apparent. Conditions which existed when institutions for higher education and research were established in this country have materially changed, and the old forms of organization are now in many cases a serious hindrance to their best development.

The experiment station is by law organized as a department of the college with which it is connected. It differs from the ordinary college department in being charged with the work of investigation, rather than instruction, and in having definite relations with a great industry, for whose promotion it was especially established. Through its correspondence, publications, inspection service, and association with the farming community it has an increasing amount of business not immediately relating to its investigations but requiring special knowledge and skill for its successful discharge. To do most effective work the operations of the station must proceed in accordance with a well-matured plan which involves the cooperation of different members of the staff.

So extensive and important has the business of the stations become that their proper management requires the time and energy of an executive officer, or director. In some cases it may still be possible for the director to conduct investigations in some special line or do a limited amount of teaching, but as a rule he can do little beyond attending to administrative duties. In a number of institutions prudential reasons of various kinds have led to the combination of the offices of president and director. Whatever justification there may have been for this in the past, there is little excuse for it at the present. The duties of the college president are too manifold and onerous to permit his giving much attention to the special needs of an experiment station. His directorship almost necessarily becomes a nominal affair. This arrangement has not worked well, and should be universally abandoned.

As regards the business of the station, the director should be clothed with a large measure of authority and consequent responsibility; should

plan and supervise its work and expenditures, and control its staff to such an extent as will bring them together to work as a unit for the promotion of the station's success. The members of the staff should be directly responsible to the director on all matters relating to the station, whatever their position may be in other departments of the college, and should expect to transact station business through the director rather than through the college president or the governing board. A proper independence in the conduct of investigations, or parts of investigation, in their respective specialties, and just credit for their share in the station's operations as set forth in publications, or otherwise, may, it is believed, be amply secured for the expert officers of the stations at the same time that good discipline is maintained and ample provision made for united effort.

No class of men need to readjust their professional code to the modern requirements of the organization of great scientific and educational enterprises more than college professors and scientific specialists. A way must be found by which teaching and research can be conducted on a system which combines liberty with law. The old régime of the entirely independent teacher and investigator has passed away. The specialization, which is simply a form of the division of labor well-known in industrial pursuits, carries with it a necessity for combination of workers in educational and scientific institutions as well as in manufacturing establishments. In a way hitherto unknown scientific men will be called in the future to work together for common ends.

One of the greatest difficulties in the management of these institutions arises from the fact that while specialization has narrowed the field and outlook of the individual officer, there has not been a corresponding recognition of the necessity of readjusting the form of organization and the spirit of the worker to meet these new conditions. At no time has there been greater need of the cultivation of an earnest and enthusiastic *esprit du corps* among the rank and file of educational and scientific workers. Obviously it should especially be a virtue characteristic of men connected with public institutions. The officers of our agricultural colleges and experiment stations are public functionaries employed to advance very important public interests. With them the good of the community, as involved in the success of the enterprise with which they are connected, should be the ruling motive of action. The fame and emoluments of the individual worker should be subordinated to the requirements of concerted action for a common end. And yet in the long run it is believed the individual worker as well as the institution will profit by a loyal and self-sacrificing discharge of common duties; for union of effort will bring greater success, and whenever a college or a station is strong and flourishing credit is reflected on every worker who has contributed to this issue.

The tide is running strongly toward a more compact organization and a greater unification of the work. On the whole those stations which have a strong organization and administration are meeting with the largest measure of success.

Observation leads to the belief that a widespread differentiation of the investigator from the teacher is gradually taking place. A certain number of men are more and more devoting themselves to the work of investigation and succeeding in it. Others are just as certainly losing their interest and activity in such work. In this as in every other walk of life the personal bent and natural fitness of the man manifests itself as an important element of success which should be reckoned with by those having the administration of our colleges and stations. This differentiation of the investigator from the teacher is not prevented, though it may be hindered, by the double duty which is required of many station and college men, but there is little doubt that in a large majority of cases the requirement of so large an amount of elementary instruction from men who have been appointed upon the station staffs, presumably by reason of their training and fitness for agricultural investigation, is an arrangement which has little if anything but expediency to commend it. From the point of view of the station this expediency is exceedingly doubtful. As Dr. Jordan very truly said in his paper at the last convention of the Association of American Agricultural Colleges and Experiment Stations, "The interests of our stations and, above all, the interests of our agriculture demand that the director and leading members of the staff shall be, first of all, workers for the station, and shall give to its proper activities their highest thought and their best energies. . . . It is entirely out of the question for our college professors to be tied to the insistent daily duties of instructing students and at the same time maintain the close, well-informed, and broadly helpful relation to the needs and conditions of agricultural practice. The experiment station, with an annual income second to no other department in most colleges, should not be in any sense an appendix to class-room instruction, nor was it ever intended that this should be the case. It should have a strong, well-defined, and independent individuality."

Because a man is required to teach many hours he does not thereby become a successful teacher. The research which he is compelled by pressure of college work to carry on during vacations and at night may nevertheless be his real mission. It will be well if boards and presidents will consider more fully the actual state of things, and make, as far as possible, such a readjustment that the investigator will be left very largely to investigate and the teacher to teach.

FOURTEENTH ANNUAL CONVENTION OF THE ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERI- MENT STATIONS.

E. W. ALLEN, Ph. D.

Office of Experiment Stations.

This year being the twenty-fifth anniversary of the establishment of agricultural experiment stations in this country as State institutions, it seemed especially appropriate that the convention of the Association which represents the combined interests of these institutions and the colleges with which they are affiliated should be held in the State where the station movement had its birth. The sessions on November 13 and 15 were held at New Haven, Conn., in the assembly room of the Sheffield Scientific School, and those of November 14, at Middletown in Judd Hall and the chapel of Wesleyan University. The meetings were well attended and the representation was quite general, delegates being present from every section of the country and a considerable number coming from the far West. In all, 116 delegates and visitors registered, representing 38 States and Territories and 68 institutions. The opportunity afforded for looking over the two stations in Connecticut and those in some of the adjoining States was embraced by many of the delegates who came from a distance.

GENERAL SESSIONS.

The general sessions were presided over by President J. E. Stubbs, of the University of Nevada, who delivered the presidential address on the first evening of the convention. This was a scholarly discourse on the subject, What is of most worth in modern education? The answer to this question the speaker conceived to be the exaltation of ethical values, "for the reason that ethical values are fundamental and paramount in the ideas and ideals of modern education—the ideas as representing present methods, organization, and spirit, and the ideals as setting forth the high aims of ceaseless progress toward educational perfection." Modern education seeks the development and the training of those human powers which make for individual worth and social well-being, and he urged the importance of maintaining this union of training for service and of culture for life up to the end of the broadest and most privileged education. He pointed out that "the purpose to be achieved by educators of the present time should be to

make ethical or moral values the guiding and controlling principle in the application of scientific method to education and to the organization of every school, college, or university." Speaking specifically of the duty and obligations of the colleges and universities embraced by the Association, he said: "They are indeed national institutions of learning, and in their plans and systems of study and organization they ought to give preeminence to those subjects which will secure the best results in our national life. If, as has been said, philosophy is the morality of science, and political economy is the morality of industry, commerce and agriculture, and natural law the morality of legislation, and social science the morality of history and politics, then these moralities must be the crowning subjects of education in these national institutions of learning. These represent the liberal element that must pervade all technical courses of instruction. Systematic moral teaching demands a first place."

The report of the executive committee, presented by H. H. Goodell, chairman, mentioned the favorable legislation secured at the last Congress, providing that if at any time the proceeds from the sale of public lands is insufficient to meet the annual appropriations for the land-grant colleges the deficiency shall be paid from any money in the Treasury. A section has been incorporated in a bill now before Congress, making the libraries of all the land-grant colleges depositories of Government publications. Only 25 of these colleges are now designated depositories and their continuance as such is not insured. In this connection, steps have been taken by the executive committee to insure the more prompt delivery of public documents to the designated depositories. In accordance with instructions from the last convention the executive committee secured a place on the programme of the National Educational Association for 1900, in order to present the mission and scope of the land-grant colleges in the American system of education, and the paper was presented by President Beardshear, of Iowa, at the meeting held in Charleston, S. C. The committee called attention to repeated violations of the franking privilege, and recommended "that a codification of the postal regulations be made and sent to each president and director, urging his strict compliance with the law."

President Hadley, of Yale University, addressed the Association briefly, after which a recess was taken to enable members of the Association to meet him.

The report of the treasurer showed that the expenditures during the year had amounted to \$2,019.08, leaving a balance of \$112.97 in the treasury.

The report of the section on horticulture and botany, presented by S. A. Beach, showed that in the work of teaching increased attention is being given to physiological botany. Attention was called to the

growth of nature study and extension work and the recent establishment of a chair of university extension at Cornell University. The work of the station horticulturists as evidenced by their publications was classified, showing that much the largest amount of the printed matter, aggregating nearly one-fourth, related to variety testing, horticultural methods and management ranking second. In reply to the question as to the lines of investigation considered of most importance, the opinions of 44 horticulturists were summarized, bringing out the fact that opinion is at present about equally divided in regard to the importance of plant breeding and variety testing. "There is undoubtedly greater need for variety testing in some sections than in others. In those States where horticultural interests have become well established it is vastly more important to understand more fully the scientific basis of horticultural operations than it is to increase the list of horticultural varieties which are adapted to those sections." Professor Beach referred to the frequent pressure on the horticulturists to do work of a more popular character, and the numerous demands made upon their time and funds for work which is not strictly experimental, showing that in many cases real investigation was practically precluded by the conditions imposed. He urged greater opportunities, in the way of time, funds, and competent assistants, for conducting more scientific investigations in horticulture.

In the report of the section on entomology H. Garman reviewed the present condition of entomological work at the colleges and experiment stations, indicating that much progress is being made in the specialization of the work of entomologists and in the improvement of facilities for research and instruction. About 90 per cent of the colleges and stations now employ entomologists. He noted the growth in recent years in the amount of inspection work required of station entomologists and discussed the best methods of managing this work. It was shown that the inspection of nurseries has led to the exercise of greater care on the part of nurserymen, which has diminished the prevalence of all kinds of injurious insects. The necessity for efficient assistants, especially where inspection work is carried on, was emphasized.

The report of the section on mechanic arts was read by C. S. Murkland. This traced the growth and popularity of the mechanic arts department of the colleges, and pointed out the present relative significance of its courses and the limitations of its work.

The committee on the collective experiment station exhibit at the Paris Exposition made its final report through H. P. Armsby, its chairman. This report described the plan of the exhibit, its preparation and installation, and recommended that the exhibit be kept intact and installed as a permanent exhibit at some place in Washington. The informal report which has been received of the recommendations

made by the class jury indicates a liberal recognition of the merits of the exhibit as a whole, and of its separate parts. No formal notice has been received, however, of the awards as finally made by the superior jury, which passed upon the recommendations of all the juries.

The report of the committee on engineering experiment stations was presented by C. S. Murkland. No attempt had been made to secure Congressional action during the past year and the outlook in that direction was considered less favorable than formerly. The committee accordingly recommended its discontinuance. In adopting this recommendation the Association recorded its judgment that "such stations are demanded by the industrial necessities of the age and should receive favorable consideration by Congress in view of the inestimable benefits that would accrue from them to the people."

The committee on graduate study at Washington made the following recommendations, which were adopted by the Association: "In view of the improbability that the Smithsonian Institution will adopt the suggestions of this Association regarding the organization of a Bureau of Graduate Study, your committee recommends that the Association take no further action in this direction. The committee also believes that for the present further advantage should be taken of the foundation already successfully laid by the Secretary of Agriculture, and it therefore recommends that the Association express its appreciation of the practical efforts which he has made on behalf of this movement, and ask him to consider the practicability of enlarging the present plan for graduate study in that Department, and, if he deems it wise, to invite the cooperation of other departments of the Government, in order that wider opportunities may be open to the graduates of the institutions represented in this Association, as well as of other institutions, to engage in graduate study and research in connection with the work of the National Government."

Dr. Bernard Dyer, of London, England, attended the convention as the representative of the Lawes Agricultural Trust, and delivered a course of three lectures based principally on the investigations, at the Rothamsted Experiment Station, of soils which have been in continuous wheat culture. Samples of the soils from plats which had received different fertilizing materials or none, representing different depths up to 90 in., have been taken at intervals of several years, the last series reported upon being taken in 1893, after being in wheat for 50 years. In all, between 4,000 and 5,000 samples have been studied. Dr. Dyer's lectures dealt with the results of these studies as related to the principal fertilizing ingredients and chlorin in the soils, their availability, migration in the soil and subsoil, leaching, etc. The fallacy of soil analysis without reference to the form or

availability of the constituents was shown very forcibly; for instance, in some cases over a ton of nitrogen per acre was found within the first 9 in. of soil, but the crop showed that it was starving for lack of available nitrogen. As a rule, the Rothamsted soils contain only about 30 to 40 lbs. of nitrogen per acre which is available under the most favorable conditions. Continuous wheat culture was shown to be of necessity an extravagant practice, as the wheat is harvested before nitrification in the soil is completed, and there being no crop to take up the nitrified nitrogen the nitrates are washed out by the rains. The indications are that very little nitrification takes place in the depths of the subsoil, and that these stores of nitrogen are unavailable to plants to any degree. A study of the drainage waters indicates that the ammonia salts rob the soils of lime, rather than the nitrate of soda, as sometimes claimed. Many other interesting points were brought out in regard to the chlorin content of soils, the availability as affected by different fertilizer mixtures, and the effect of other conditions on the rise and fall of the fertilizer elements in the soils. The investigation is one of the most extensive and systematic of its kind, and affords much material for careful study. It is expected that Dr. Dyer's lectures will be published later by the Department.

Besides resolutions of thanks to Dr. Dyer, the Association adopted a memorial expressing its high appreciation of the life and work of the late Sir John Bennet Lawes and his associates at the Rothamsted Station.

A carefully prepared and eloquent address on the career of the late Senator Justin S. Morrill, of Vermont, was delivered by President G. W. Atherton. President Atherton's close association with Senator Morrill for many years and his intimate familiarity with the history of the movement for the establishment of colleges and experiment stations under national auspices enabled him to treat this subject in a very thorough and satisfactory manner, so that his address will have a permanent historical value. By vote of the Association it is to be published separately.

One of the most important subjects on which the Association took action was the report of the committee on cooperative work between the Department of Agriculture and the experiment stations. This was carefully prepared by a representative committee after consultation with the directors of the stations, and was unanimously adopted by the Association. It commended the attitude of the present Secretary of Agriculture towards closer cooperation between the Department and the stations, and pointed out the different ways in which the two institutions might aid each other. It also outlined the principles on which, in the opinion of the committee, the joint work should be arranged and conducted. It was held that both the Department and the stations should feel entirely free to propose or decline cooperative

work; that in undertaking such work the autonomy of the stations should be preserved, and the arrangements made between the stations, as such, and the Department, as such, instead of through individuals; that the cost of cooperation should be borne jointly by the station and the Department; that the results of the investigation should be available to both institutions, priority of publication being a matter of mutual agreement at the outset, and that reasonable mutual assurance should be given of continuance until the work undertaken is completed. "Your committee deems it very desirable that independent work be not undertaken in the several States by the Department without the knowledge of the station or consultation with the station, particularly along lines of investigation in which the State station is engaged. Whenever cooperation with practical men in the States is desired by the Department in investigations, it is suggested that the State station be the agency through which such cooperation is conducted."

The day spent at Middletown was especially interesting and enjoyable. A general session was held in the chapel of Wesleyan University in the forenoon, at which the delegates were welcomed by President Bradford Raymond, and interesting papers presented by W. H. Jordan on American agricultural experiment stations, and by W. O. Atwater on the History of the Connecticut experiment stations. Lunch was served in the gymnasium, after which the Atwater-Rosa respiration calorimeter was viewed in operation and explained by Professor Atwater and his assistants. Section meetings were held during the afternoon, following which an informal reception was tendered the delegates at Professor Atwater's residence.

In his paper on the American stations Dr. Jordan reviewed the rise and rapid growth of the experiment-station movement in this country, and, after enumerating many of the more important results of the work of the stations, considered their general organization and the relations of station workers to the colleges in the matter of teaching. He pointed out very forcibly the evils resulting to station work from requiring excessive college duties, and urged the necessity for "a station director who is that and nothing more. In the multitudinous duties of administration, in the broad relations which he should sustain with the agriculture of the State, in deciding upon the most useful lines of work, in the sympathetic attitude of encouragement and if possible of inspiration which he should maintain toward his associates, there is abundant opportunity for the full exercise of the largest ability and the most untiring energy. If there is any official in our land-grant colleges other than the president who should not be halved, it is the station director." He then considered the character of work being conducted by the stations, as judged by their publications, deploring the fact brought out that 41 per cent of the pages of the bulletins issued in 1898 and 1899 "had no other purpose than the

diffusion of existing knowledge," and that the preparation of this class of bulletins "appears to be materially increasing, when it ought to be decreasing." He made an earnest plea for greater attention to thorough and conscientious scientific research and investigation, which he held to be the prime object for which the stations were established and in the end the most profitable field of activity.

By vote of the Association Dr. Jordan's paper is to be published separately.

A brief report by the bibliographer, A. C. True, enumerated some of the more important pieces of bibliographical work in lines related to agriculture which have appeared during the past year.

The report from the committee on uniform fertilizer laws, presented by H. J. Wheeler, stated that no attempt had been made to secure national legislation leading to uniform laws, but that several States had taken steps in the direction of greater uniformity, and it was believed that something might yet be done.

The committee on nomenclature made no report, but proposed that the committee be discontinued, which it was voted to do.

The committee on indexing agricultural literature made a report of progress. Additional funds are hoped for to enable the Librarian of the Department of Agriculture to begin the publication of such an index.

The holding of a summer school for graduate students in agriculture was discussed by W. O. Thompson. The idea proposed was an inter-collegiate school, the teachers to be drawn from the members of the Association and the sessions to be held at different colleges in succeeding years. The University of Ohio offered to finance the school for the first year, and it was proposed that a canvass be made with a view to holding such a session if there is sufficient encouragement in 1902. The matter was referred to the executive committee for investigation and report.

The committee on revision of the constitution submitted a report, involving some quite radical changes, which was discussed at considerable length. A number of amendments to the constitution were offered during the discussion, involving change of name of the Association, method of nominating officers, etc. The matter was laid upon the table until another year.

The committee on military instruction at land-grant colleges reported that an effort had been made to secure the privilege of graduate study at West Point to officers of college battalions. No definite action has yet been taken.

The committee on methods of teaching agriculture reported progress in completing the syllabi for the three remaining subjects. The committee was continued.

The executive committee was instructed to send a greeting to the

experiment station at Möckern, Germany, on the occasion of the celebration of its fiftieth anniversary.

A resolution offered by W. A. Henry expressing appreciation of the manual on "Agricultural Experiment Stations in the United States," prepared for the Paris Exposition, and requesting a second and enlarged edition, was adopted by the Association.

A committee, consisting of W. M. Hays, T. F. Hunt, A. A. Brigham, L. H. Bailey, and H. P. Armsby, was appointed to confer with the Secretary of Agriculture with reference to holding a conference of persons interested in plant and animal breeding.

The Association endorsed the policy advocated by the Secretary of Agriculture of paying larger salaries to experts in the Department in order to enable the Department to retain their services.

It was voted to reproduce at the Pan-American Exposition at Buffalo the cooperative experiment-station exhibit prepared for the Paris Exposition, "with such withdrawals or additions as may be deemed wise by the Office of Experiment Stations." The executive committee was instructed to take under consideration the appointment of a representative from the Association to act in connection with the dairy exhibit at the Pan-American Exposition.

Resolutions on the death of J. H. Smart and G. E. Morrow, both of whom have until recently taken a prominent part in the Association, were unanimously adopted.

Invitations were received for the Association to meet in Michigan, Mississippi, Maine, and Geneva or Ithaca, N. Y.

The following officers were elected for the ensuing year:

President, A. W. Harris of Maine; vice-presidents, J. K. Patterson of Kentucky, W. H. Jordan of New York, R. H. Jesse of Missouri, L. G. Carpenter of Colorado, and E. A. Bryan of Washington; secretary and treasurer, E. B. Voorhees of New Jersey; bibliographer, A. C. True of Washington, D. C.; executive committee, H. H. Goodell of Massachusetts, Alexis Cope of Ohio, G. W. Atherton of Pennsylvania, and H. C. White of Georgia.

Section on agriculture and chemistry.—Chairman, C. D. Woods, of Maine; secretary, H. J. Waters, of Missouri.

Section on horticulture and botany.—Chairman, L. R. Jones, of Vermont; secretary, W. J. Green, of Ohio.

Section on college work.—Chairman, J. H. Raymond, of West Virginia; secretary, B. O. Aylesworth, of Colorado.

Section on entomology.—Chairman, M. V. Slingerland, of New York; secretary, H. A. Morgan, of Louisiana.

Section on mechanic arts.—Chairman, H. W. Tyler, of Massachusetts; secretary, F. P. Anderson, of Kentucky.

MEETINGS OF SECTIONS.

SECTION ON AGRICULTURE AND CHEMISTRY.

One session of this section was given up to discussions of investigations on tobacco, another to the energy of foods and feeding stuffs, and the third to miscellaneous papers. E. H. Jenkins presented a paper on Methods of experimenting with cigar wrapper leaf tobacco, in which he discussed the conditions which should govern in cooperative experiments, the relations of the station with the experimenter, etc. The station should, if possible, own the land where the experiment is made and always the crop, since the interests of the grower and the experimenter are not the same. All the operations in the field should be in charge of an experienced man, as no general directions can be given in advance. Comparisons should be made only after the fermentation has taken place, that is, in the finished product, and the product should be judged by dealers in the leaf, as the "quality" is subject to the whim of the cigar maker and the trade. Quality was defined as the "fitness to meet the present tastes of the manufacturer of cigars—nothing else." In conclusion, the work of the Connecticut State Station covering a number of years in cooperation with the Connecticut Tobacco Experiment Company and later in cooperation with the Division of Soils of this Department, was reviewed and the methods followed detailed.

The growing and curing of Burley tobacco was described in a paper by M. A. Seovell, the practice of the most intelligent growers in Kentucky and lower Ohio being given. The origin of the White Burley by selection from the Red, and its characteristics and curing were described. It is not fermented and is used mostly in the manufacture of chewing tobacco. It can absorb as high as 40 per cent of its weight in sugar and flavoring extracts, which adapts it to making plug tobacco. "Perhaps the soil has the greatest influence of any one thing in determining the quality of [Burley] tobacco, especially its color," although the season has a marked influence on the quality. There was believed to be a good field for station work in experimenting with fertilizers for Burley tobacco, curing, and selection to get a light leaf.

Milton Whitney described the work of the U. S. Department of Agriculture with tobacco, mentioning briefly the lines of work which have been taken up. In cooperation with the Connecticut State Station Sumatra tobacco has been grown under shade, which, it was stated, experts can not distinguish from the imported leaf.¹ It was believed to be possible on the best tobacco soils to grow Sumatra which will be

¹ The crop has since been sold at an average price of 71 cents per pound, including tops, butts, and trash. As high as \$1.25 per pound was received for some of the unsorted product.

equal to the imported article. Work has been taken up with the Pennsylvania filler tobacco, and it is believed that the Cuban type can be approximated in parts of Pennsylvania and more closely in Ohio. The case rot, it was stated, causes a loss of about \$1,000,000 annually in Pennsylvania, which can be prevented by proper methods of handling, and this matter is being investigated. A soil survey is being made in Pennsylvania and Ohio in order to determine the tobacco districts with a view to selecting the best kinds to grow. In Florida, where the finest type of cigar leaf tobacco in this country is being produced, the quality varies greatly in adjacent localities. A soil survey will be undertaken there to study this matter. Texas is believed to afford an opportunity to develop the Cuban filler industry. A soil survey will be made there also as a basis for this industry, as the regions especially adapted are supposed to be limited. The tobacco exhibit at the Paris Exposition, which was made under the supervision of the Division of Soils, was described, together with the successful competition of the American grown tobacco with the choice tobaccos of other countries.

A paper, entitled *What is available energy*, was read by W. O. Atwater, defining this term and describing the means by which this value is determined. The subject was discussed by W. H. Jordan, H. P. Armsby, and C. D. Woods, indicating some confusion in the use of the terms *available foods*, *available energy*, *actual available energy*, etc

A paper by E. B. Voorhees on *Cooperative field experiments*, outlined the form which the cooperation with farmers should take and the part to be performed by both the station and the farmer. A close supervision over all the separate steps up to the weighing of the final crop was advocated. He cited a number of evidences of the value and utility of cooperative fertilizer experiments in New Jersey. The educational effect on the farmer himself was held to be one of the chief elements of value.

C. S. Phelps described the cooperation between the Connecticut Storrs Station and farmers in testing dairy herds. This work has been in progress for 7 years and has been carried on at 40 separate farms. It was held to be of use to the farmers in improving their rations and to the station in affording a means of testing narrow rations.

In a paper on *Our new agricultural industry*, I. P. Roberts described the growth of the sugar-beet industry in this country and some lines in which experimental work is still needed.

SECTION ON HORTICULTURE AND BOTANY.

A paper on *Plant physiology in its relation to agriculture and horticulture*, by A. F. Woods, outlined the requirements of the vegetable physiologist, advocated more thorough training in this subject in

the colleges, and enumerated some of the problems which need investigation.

Laboratory and field work for students in horticulture was discussed by E. S. Goff, who laid much stress on the educational value of work of this character, holding that the student who is to become a horticulturist should be trained in the practical operations of the art.

F. W. Card discussed the Educational status of horticulture, emphasizing the educational value of the study of horticulture, and John Craig described the nature study movement and its workings in New York State.

G. E. Stone presented a paper on The function of the station botanist, the central idea of which was that the function of the station botanist is primarily research, the nature of which must bear intimate relation to agriculture.

The grass and forage plant investigations in the Department of Agriculture and the experiment stations was reviewed by T. A. Williams, especial attention being given to the history of this work in the Department of Agriculture, the lines of work pursued by the Division of Agrostology, and cooperative work with the experiment stations. In conclusion, some of the important results of grass and forage plant investigations were enumerated. The author urged the importance of this line of investigation and pointed out the advantages of cooperation.

Progress of variety testing in experiment station work was the subject of a paper by F. W. Rane. He showed that "while most stations are doing more or less with varieties the general feeling seems to prevail among station workers that after all it is not worth the time and expense necessary." The really new introductions each year were shown to be few, the total number for 1900, as shown by an examination of catalogues of 12 of the largest seedsmen, being 24 varieties of vegetables. The view was expressed that by properly systematizing the work the expense and labor of variety testing might be reduced, and that if properly managed it constituted a legitimate line of horticultural work.

B. D. Halsted showed what the experiment stations have done in originating varieties of plants by crossing and selection, the various lines of activity in this regard at different experiment stations being summarized. Extensive work is in progress in the improvement of corn, cotton, wheat, fruits, vegetables, and other agricultural plants.

The relation of the Section of Seed and Plant Introduction to experiment stations was presented by J. G. Smith, who reviewed the history of the section, the work which it is doing in cooperation with the stations, and some of the more important results. W. E. Britton described a vegetation house arranged for pot experiments.

SECTION ON ENTOMOLOGY.

The attendance of entomologists at this convention was larger than usual and a full programme was presented. W. E. Britton reported experiments on the banding of trees to prevent their injury by the fall cankerworm. Black Virginia oil was found to be better for this purpose than printer's ink.

E. P. Felt presented Suggestions toward greater uniformity in nursery inspection laws and rulings. There was said to be a growing demand for fumigated trees, and the author believed it was better to educate the public rather than to try to enforce laws. Papers on Nursery inspection and orchard insecticide treatment in Illinois, by S. A. Forbes, and Experience in nursery and orchard inspection and some recent results with hydrocyanic-acid gas in large buildings for the destruction of insect pests, by W. G. Johnson, described different phases of this work, and the subject of fumigation was discussed at some length.

Notes on crude petroleum and its effect upon plants and insects were presented by J. B. Smith. When the plants are dormant this may be used even undiluted if the crude oil is pure, but if either gasoline or paraffin has been removed the residue becomes dangerous to the trees. The crude oil should not be used in summer or when the trees are in foliage.

A power sprayer for asparagus was described by F. A. Sirrine. This machine sprays the plants from four directions at once, thus making the treatment very thorough and effective. The same author described a little-known asparagus pest (*Agromyza simplex*) which works in the cambium layer principally, damaging seedling beds more particularly. It is controlled by plucking and burning infested plants.

Other papers read before this section were Entomology in the Southern States, by H. Garman; Danger to American horticulture from the introduction of scale insects, by G. B. King; Observations on *Artuce punctistriqua*, by H. A. Morgan; and Entomological œcology, by C. W. Woodworth.

SECTION ON COLLEGE WORK.

The only formal paper before this section was one by J. K. Patterson on the General drift of education at the land-grant colleges, the time being occupied by discussion of various subjects.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The estimation of alumina and ferric oxid in natural phosphates, F. P. VEITCH (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 5, pp. 246-258).—This article discusses the sources of error in older methods, reports the results of a study of the various factors influencing the accuracy of the determinations, and describes the following method, based upon the results of these experiments:

“Treat 1 gm. of substance in a platinum dish with from 5 to 10 cc. hydrofluoric acid, let stand in the cold from 2 to 3 hours, heat on the water bath to complete dryness, add 2 cc. concentrated sulphuric acid, running well around the sides, and heat at a low temperature until the substance no longer flows in the dish. By this process fluorin is completely expelled. Cool and add from 10 to 20 cc. concentrated hydrochloric acid, and warm a few minutes to soften the mass; transfer to a small beaker, and boil until all aluminum compounds are surely dissolved (15 to 30 minutes); filter from undissolved residue, if any, washing the filter thoroughly, add 50 cc. 25 per cent ammonium chlorid solution and ammonia until alkaline, then hydrochloric acid until the precipitate just dissolves. Cool, dilute to about 250 cc., and add 50 per cent sodium thiosulphate solution, drop by drop, until the solution is colorless, adding in all 20 cc.; cover with a watch glass, boil half an hour, filter, wash back into the same beaker, and dissolve in boiling hydrochloric acid; reprecipitate exactly as before, after adding 2 cc. of a 10 per cent ammonium phosphate solution. Wash 20 times with 5 per cent ammonium nitrate solution, and ignite to constant weight. For the second precipitation ammonium thiosulphate may also be used, but it is not strictly necessary.”

A new method for the determination of aluminum, E. T. ALLEN and V. H. GOTTSCHALK (*Amer. Chem. Jour.*, 24 (1900), No. 4, pp. 292-304).—The method proposed is as follows:

“Dissolve the substance in which the aluminum is to be determined in water or a mineral acid. In case the latter is used, nearly neutralize with ammonia. Now dissolve a stick of potash in which the silica, iron, and alumina are known, in a measured quantity of water, and mix thoroughly. One to two grams of potash should be sufficient. Pour the potash solution into a burette, and thence introduce into the aluminum solution a quantity of the former, sufficient to redissolve the precipitate which first forms. If the solution is still turbid no harm is done, but any considerable excess of potash should be avoided. [Soda] may be used as well as potash. Now pass a stream of carbon dioxid into the solution. If the alkali is not in too great excess, precipitation begins in a minute or two. Twenty minutes should suffice to precipitate 0.200 gm. Al_2O_3 . The bulk of the alumina comes down in a few minutes, and filtration then proceeds without difficulty. Transfer the precipitate for the most part to a 9 cm. filter and wash several times without suction. The soluble impurities are now mostly removed. Break the paper with a stirring rod, wash back completely

into the original beaker, and boil the precipitate a few minutes with about 150 to 200 cc. water containing a little pure ammonium chlorid or nitrate. The boiling should be continued only 2 or 3 minutes, otherwise the precipitate does not settle well. As soon as it has settled, pass the supernatant liquid through a new filter, using this time a pump and cone. Repeat the boiling and decantation once or twice, transfer the precipitate to the filter, and wash several times with hot water. Suck dry and transfer to a covered crucible, which has been weighed. Dry carefully over the flame, burn the paper, and heat from 5 to 10 minutes at the highest temperature of the blast lamp. Cool from 10 to 15 minutes in a sulphuric acid desiccator, and make an approximate weighing. Heat again for 5 minutes, cool as before, and weigh as directed. From the weight of the precipitate subtract the weight of the impurities in the potash."

A study of the conditions affecting the accuracy of the method is reported.

Estimation of calcium carbonate in soil, H. SCHÜTTE (*Ztschr. Angew. Chem.*, 1899, p. 854; *abs. in Analyst*, 25 (1900), May, p. 132).—It is claimed that the Stutzer and Hartleb method (*E. S. R.*, 11, p. 110) does not give accurate results when applied to some soils, especially those poor in calcium carbonate and containing zeolites. Immendorff's method, carried out as follows, is recommended: Extract the soil with hot hydrochloric acid, make a portion of the solution alkaline with ammonia, warm, clear up with a little acid, and boil. Add a large excess of a strong solution of ammonium oxalate, boil for some time, make alkaline with ammonia, and then faintly acid with acetic acid. Determine the calcium oxalate by titration, or preferably (if the soil contains much iron) collect it on a filter, ignite, and weigh.

Direct estimation of calcium in the presence of iron and aluminum, L. BLUM (*Ztschr. Analyt. Chem.*, 39 (1900), No. 3, pp. 152–155).—This method is used in estimating calcium in iron ores and blast-furnace slags. The calcium is precipitated by ammonium oxalate, the iron and aluminum being held in solution by the presence of tartaric acid added to the ammoniacal solution. By this procedure small amounts of oxids of iron, aluminum, and manganese are carried down with the calcium oxalate, but this is said to be very nearly compensated by the calcium that is not precipitated. This is a very short and practical method, but can not be used with substances containing more than 0.5 per cent of manganese.—C. B. WILLIAMS.

Soil humus—some sources of error in analytical methods, A. L. EMERY (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 5, pp. 285–291).—Three sources of error are discussed, namely, the expulsion of ammonia from organic matter during leaching with caustic potash, the absorption of ammonia by the humus extract when the soil is leached with ammonia solution, and the loss of organic matter in washing with hydrochloric acid to remove lime. The author proposes to overcome the first difficulty by the following means: "The soil to be leached with caustic potash is placed in a funnel which is closed at the top with a stopper through which the leaching solution is admitted by a separatory funnel.

The glass support of a Gooch crucible serves very well for the funnel holding the soil. The solution from the soil is run directly into dilute sulphuric acid, the bottle containing the same being sealed with a U-tube containing sulphuric acid. Gentle suction can be applied to this apparatus, which greatly hastens the process without the least danger of losing ammonia." For the second and third difficulties no remedy is offered.

The relation of chemistry to the progress of agriculture, H. W. WILEY (*U. S. Dept. Agr. Yearbook 1899*, pp. 201-258, pls. 2). This is a review of agricultural chemistry during the nineteenth century, treating especially of the progress made in the United States. The subject is divided for the purpose of discussion as follows:

"(1) The relation of chemistry to agriculture at the beginning of the century.

"(2) The impetus given to scientific agriculture in its relation to chemistry by the discoveries of Liebig, Gilbert, Boussingault, and other workers, which began to produce effects about the middle of the century.

"(3) A résumé of the relations of chemistry to agriculture up to and at the present time, with a brief reference to the principal methods whereby chemical research has been made useful to practical agriculture."

On a new method of determining aluminum, A. STOCK (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 4, pp. 175-178).—A method based on the separation of iodine and the precipitation of aluminum hydrate when a solution of an aluminum salt is treated with a mixture of potassium iodide and iodate is described.

A process for the determination of carbon dioxide in carbonates, R. E. DEVINE (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 8, pp. 473-476, fig. 1).—A description is given of a method based on the principle of Pettenkofer's process, "namely, absorption of the carbon dioxide by a measured amount of standard baryta water (solution of barium hydroxide), and titration of an excess of the latter with a standard acid." The apparatus used by the author in carrying out this method is also described.

Note on the peculiar difficulties which beset the application of the ammonia method to the analysis of sewage and sewage effluents, J. A. WANKLYN (*Chem. News*, 81 (1900), No. 2115, pp. 268, 269).—The results of analyses of a number of samples of sewage effluents are reported which go to show "that no return of the albuminoid ammonia in sewage or sewage effluent is trustworthy unless adequate precautions have been taken to avoid mistaking urea for the complex nitrogenous organic substances which yield albuminoid ammonia."

Apparatus for the determination of ammonia in water by the Wanklyn method and total nitrogen by the Kjeldahl method, R. S. WESTON (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 8, pp. 468-473, figs. 2).—The apparatus described is a modification of the Johnson apparatus, improved by Hazen, Clark, and others, adapted to water analysis. The apparatus is so arranged that both the distilling flasks and the receivers are brought to the front and are thus readily accessible to the operator.

A new simple method for the quantitative determination of nitric acid in water, N. N. KOSTJAMIN (*Vrach [St. Petersburg]*, 21 (1900), p. 728; *Pharm. Ztg.*, 45 (1900), p. 646; *abs. in Chem. Ztg.*, 24 (1900), No. 62, *Repert.*, p. 218; and *Chem. Centbl.*, 1900, II, No. 16, p. 878).—The method is as follows: Put 5 cc. of the water in a porcelain dish, add slowly (about 2 cc. per minute) and with constant stirring brucin-sulphuric acid (1 part of brucin to 3,000 parts pure sulphuric acid) until the solution shows a uniform clear rose color. The sulphuric acid sets the nitric acid free and this forms, with the brucin, methyl nitrite (CH_3NO_2), kakotelin ($\text{C}_2\text{H}_{22}(\text{NO}_2)_2\text{N}_2\text{O}_5 + \text{H}_2\text{O}$), and oxalic acid. A table is given from which can be found the N_2O_5 corresponding to the amounts of reagent used.

Estimation of urea in urine, A. JOLLES (*Ztschr. Analyt. Chem.*, 39 (1900), No. 3, pp. 137-145).

The iodine and bromine values of oils and fats, R. WILLIAMS (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 4, pp. 300, 301).

Notes on linseed oil analysis, P. C. McILHINEY (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 4, pp. 320, 321).

On a new general reaction for albuminoid substances, A. P. LIDOF (*Zhur. Russ. Fiz. Khim. Obshch.*, 31 (1899), p. 781; *abs. in Bul. Soc. Chim. Paris*, 23 (1900), No. 13, p. 622).

The composition of the albumin of the seed of the honey locust (*Gleditschia triacanthos*), M. GORET (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 1, pp. 60-63).

Gypsum and limestone, G. W. SHAW (*Oregon Sta. Bul.* 62, pp. 14-17).—Descriptions and analyses are given of 12 samples of gypsum and 19 samples of limestone, mainly Oregon products.

On an improved absorption apparatus for use in the analysis of essential oils, A. C. CHAPMAN and H. E. BURGESS (*Analyst*, 25 (1900), Aug., pp. 197-199, fig. 1).

A platinum crucible for the determination of alkali according to Lawrence Smith, J. KÖNIGSBERGER (*Chem. Ztg.*, 24 (1900), p. 690; *abs. in Chem. Centbl.*, 1900, II, No. 12, p. 689).—Instead of the deep crucible ordinarily used, the author employs a crucible of the usual form with a close-fitting cylindrical cover for the fusion of silicates with calcium carbonate and ammonium chlorid in the determination of alkalies according to Smith's method.

An addition to the apparatus used in the estimation of nitrogen by the Kjeldahl method, H. MEHRING (*Ztschr. Analyt. Chem.*, 39 (1900), No. 3, pp. 162, 163).—Instead of a bulb tube to connect the distilling flask with the condenser, the author uses a wide tube bent twice at obtuse angles in opposite directions, with each end drawn out to make connection. The end connecting with the flask is straight, narrow, and vertical, and in it will form a column of water that will wash the vapor forced through the condenser. The end connected with the condenser is in the shape of a swan's neck. This apparatus is claimed to be durable and efficient.—C. B. WILLIAMS.

Asbestos filters, O. LOHSE and P. THOMASCHESKI (*Ztschr. Analyt. Chem.*, 39 (1900), No. 3, pp. 158-161).—To test the value of the Lohse asbestos filter the authors have made many estimations of silver, barium, chlorine, nickel, and sugar (reduction) with closely agreeing results.—C. B. WILLIAMS.

A modification of the Bunsen vacuum pump, M. H. ITTNER (*Amer. Chem. Jour.*, 24 (1900), No. 3, pp. 253-255, fig. 1).

BOTANY.

Report of the botanist, C. E. BESSEY (*Nebraska Sta. Rpt.* 1899, pp. 28-34).—This report contains notes on various plant diseases, poisonous plants, weeds, grasses, forage crops, and the trees of Nebraska. The occurrence of carnation rust is noted, and its prevention by proper management of carnation houses is predicted. A potato disease which produces brown discolorations within the tuber, eventually destroying it, is reported to be rather widespread throughout the State. The author plans to continue his studies on this disease until able to make some definite suggestions regarding its nature and means of eradication. At present it is suggested that in planting no tubers showing any well-marked brown discolorations should be used. Investigations

have been begun on the poisonous plants of the State and a report on the subject will be made later.

Attention is called to the native thistle (*Chicus undulatus*) and wild morning-glory (*Convolvulus arvensis*). Both of these weeds seem to be spreading, and indications are that unless carefully attended to they will prove troublesome. The Russian thistle, which at one time seemed to threaten the crops of the State, has ceased to be troublesome, and the author states that rarely is a large specimen seen in the vicinity of the station.

The accumulation of asparagin in legumes grown with insufficient light, E. BRÉAL (*Ann. Agron.*, 26 (1900), No. 1, pp. 5-19).—An account is given of some investigations on a number of white, blue, and yellow lupines grown from September until March in a well-heated greenhouse, but which did not receive any direct sunlight after 10 a. m. The plants were grown in water cultures and received no nitrogen, but were given potassium phosphate, potassium chlorid, and magnesium sulphate. The seeds were first washed with corrosive sublimate, germinated between papers, and transferred to the water cultures as soon as their roots were well formed. They made good growth and showed no indication of etiolation.

A large number of plants were examined, the methods being given in detail, and proportionately large increases were noted in their asparagin content. White lupines were found to contain as much as 50 per cent of their dry weight in asparagin, while the seeds contained but 0.6 per cent. Blue lupines analyzed entire contained 37 per cent of asparagin, and other plants kept for 15 days in the dark contained 44 per cent of their dry weight. In April, the sun having ascended, the house was well lighted and plants analyzed after that time showed progressively less asparagin. Experiments with wheat, sunflowers, and gourds showed no accumulation of asparagin. The results obtained with lupines agreed with those of Prianisnikow.¹

Other experiments are reported in the same article. Lentils deprived of their cotyledons and placed with their roots in starch solutions took up some of the carbohydrates, and some given both starch and mineral matter made better growth than a check lot without starch.

White lupines were made to absorb considerable quantities of potassium humate through tubes containing solutions of the compound being thrust into their stems.

Concerning the pectic matter of plants, A. HÉBERT (*Ann. Agron.*, 26 (1900), No. 1, pp. 34-50).—The author examined the pulp of ripe fruits and the roots of carrots, beets, etc., for pectin, pectose, pectic acids, etc. The principal substances found were pectin and pectic acid. The pectins give viscid solutions in water and are coagulated by the addition of alkalis. When treated with potash they give pectic acid.

¹ Landw. Vers. Stat., 52 (1899), No. 1-2, p. 137-164.

The ferment pectase acting upon pectin also gives pectic acid. By hydrolysis the pectic bodies yield pectoses, and especially arabinose. By oxidation they yield mucic acid. From this it is concluded that pentosan and galactan are present in the molecule of pectic bodies.

It is claimed that the investigations of the author, as well as all recent work, indicate that the pectic bodies are formed by the chlorophyll of the plant.

On the hybrid fecundation of the endosperm of maize, H. DE VRIES (*Rev. Gén. Bot.*, 12 (1900), No. 136, pp. 129-137, pl. 1).—A review of some of the literature bearing upon the immediate effect of pollen, or xenia as it has been called, is given, together with an account of the author's experiments with maize. The experiments are fully discussed and the conclusion reached that the effect commonly noted as the result of crossing different races or varieties of maize is due to double fecundation. Wherever a grain of corn shows the characteristics of the male parent in the endosperm it is the result of hybrid fecundation. Where the characteristics of the female parent are exhibited it is a case of self-fertilization. The explanation of these phenomena is to be found in the discovery of double fecundation by Nawaschin and Guignard.

Progress of plant breeding in the United States, H. J. WEBBER and E. A. BESSEY (*U. S. Dept. Agr. Yearbook 1899*, pp. 465-490, pls. 3, figs. 2).—The early horticultural and agricultural conditions of the United States are described, together with early methods of plant breeding. The improvements effected during the past century are mentioned more or less in detail, being grouped under the different headings of fruits, berries, vegetables, cereals, ornamentals, nuts, cotton, etc.

Progress of economic and scientific agrostology, F. LAMSON-SCRIBNER (*U. S. Dept. Agr. Yearbook 1899*, pp. 347-366, figs. 5).—The early investigations relating to grass and forage plants are briefly described, together with a description of the establishment and work of the Division of Agrostology of this Department. The grass investigations which have been conducted in different parts of the country are outlined and descriptions given of some of the more valuable grasses and forage plants.

Economic grasses, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Bul. 14*, rev., pp. 85, pls. 3, figs. 91).—This bulletin, which is a revised edition of a previous one (*E. S. R.*, 10, p. 718), contains much of the economic information given in Bulletin 3 of this Division (*E. S. R.*, 8, p. 687).

Seedling forms of New Zealand phanerogams and their development, L. COCKAYNE (*Trans. and Proc. New Zealand Inst.*, 31 (1898), pp. 354-398, pls. 5).—A biological study of a large number of seedling forms of New Zealand plants.

The mistletoe, J. HUBERTY (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), Nos. 4, pp. 284-290; 5, pp. 373-381; 6, pp. 443-451).—The life history of the mistletoe is reviewed at considerable length, and its method of attacking the host and the effect, as shown by analyses of the wood of infested and sound trees, is described. Various means of destroying mistletoe are suggested, among which the cutting away of the branches is probably the most efficient.

Photometric investigations in vegetable physiology, WIENNER (*Bot. Centbl.*, 82 (1900), No. 10-11, pp. 316-318).—A summary is presented of the author's investigations on the various adaptations of plants to light in the arctic regions.

Formation of oil in the olive, G. SPAMPANI (*Bul. Soc. Bot. Ital.*, 1899, pp. 139-143; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 3, pp. 342, 343).—A

description is given of the mode of formation of oil in the fruit of the olive. This takes place in the cells of the epicarp, especially in those of the mesocarp. The oil is not transferred to the cells where it is ultimately found, but is formed in them. In the case of the olive there is a marked illustration of the almost universal phenomenon of the presence of oily substances in the active protoplasm. This oil is not the result of the degeneration of the protoplasm, but is formed when that substance is in its most active condition.

Anatomical studies of important fiber plants of Japan with special reference to their bast fibers, K. SAITO (*Bot. Centbl.*, 83 (1900), No. 11, p. 351).

The latex system of lacquer trees and related species, T. INUI (*Bot. Centbl.*, 83 (1900), No. 11, p. 352).—The endemic species of *Rhus* were examined and a laticiferous system found in all but *R. radicans*. The method of secretion of latex and effect of external factors upon its production are briefly shown.

On the selective power of root tubercle bacteria, L. HILTNER (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 9, pp. 273-281).—Replying to a recent article by Stutzer, the author maintains that within certain limits the presence of bacteroids depends upon the host as well as upon the kind of bacteria in the soil or medium.

Nitrogenous constituents of fungi, E. WINTERSTEIN (*Bot. Centbl. Beihefte*, 9 (1900), p. 167; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 3, p. 362).—The chemical composition of fungi is said to differ in several important points from that of flowering plants. In addition to carbohydrates, the membranes contain a nitrogenous substance, chitin. In neither fresh nor dry specimens of *Boletus edulis*, *Cantharellus cibarius*, or *Agaricus campestris* was the author able to isolate proteids. From *B. edulis* and *A. campestris* leucin was crystallized and the presence of tyrosin demonstrated by Millon's reagent.

The influence of inorganic salts on the formation of conidia in *Aspergillus niger*, A. YASUDA (*Bot. Mag. [Tokyo]*, 13 (1899), p. 85; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 3, p. 364).—As the result of a series of experiments it was found that the formation of conidia is retarded in proportion to the concentration of the nutrient fluid. The size of the conidia also decreases under the same condition. The conidia bearing hyphæ become shorter, and the black color of the conidia is greatly increased. When solutions are very concentrated, the formation ceases entirely.

Fungi in juniper berries, A. NESTLER (*Ber. Deut. Bot. Gesell.*, 17 (1899), pp. 320-325, pl. 1; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 3, p. 365).—It is stated that the mycelium of a fungus is almost universally present in the so-called berries of the juniper in the second year after their formation. Experiments on infection seem to show that the change of color from green to black or blue black is due to the action of the fungus. The exact nature of the fungus has not been determined, but the incipient forms of spores resembling those of *Aspergillus* were observed. It is thought probable that there is more than one species of the fungus.

Investigations on the morphology of the stroma-forming Sphæriales, W. RUHLAND (*Sep. Hedwigia*, 39 (1900), pp. 79, pls. 3).

ZOOLOGY.

Revision of American voles of the genus *Microtus*, V. BAILEY (*U. S. Dept. Agr., Division of Biological Survey, North American Fauna* 17, pp. 88, pls. 5, figs. 17).—This bulletin contains an account of the habits, food plants, economic status, and injuriousness of the voles, or meadow mice, together with brief notes on methods of preventing injury by these animals. It is recommended that wire net-

ting, tent cylinders, burlap, twisted ropes of straw, or other substances be wrapped around trees in winter to prevent injury to the bark by voles. No direct remedy against these animals is suggested, but it is urged that means be taken to protect owls, hawks, and other animals which feed upon voles. The greater part of the bulletin is occupied with a systematic account of the species of the genus *Microtus*. Seventy species and subspecies are recognized, being distributed in 8 subgenera.

Zoological yearbook for 1899, P. MAYER (*Zoologischer Jahresbericht für 1899. Berlin: R. Friedländer & Son, 1900, pp. 489*).—This volume contains detailed lists of literature upon the following groups of animals: Protozoa, Porifera, Cœlenterata, Echinodermata, Vermes, Bryozoa and Brachiopoda, Arthropoda, Mollusca, Tunicata, and Vertebrata.

Cyanid of potassium for poisoning rabbits (*Jour. Agr. and Ind. South Australia, 3 (1900), No. 7, pp. 566-568*).—About half an acre of land was inclosed by means of wire netting in order to prevent rabbits from going to natural water sources. Water which had been poisoned with cyanid of potash in the ratio of 1:1,000 was then exposed in shallow tin vessels during the night. In the morning it was found that about 1 gal. of water had been taken by the rabbits and 11 dead rabbits were found. On the second morning 77 rabbits were found dead, the majority being fully grown. The method is believed to be effective for the destruction of rabbits.

Rodents, O. LUGGER (*Farm Students' Rev., 5 (1900), No. 21, pp. 17-19, figs. 3*).—Popular notes on rabbits and other rodents as related to agriculture.

A review of economic ornithology in the United States, T. S. PALMER (*U. S. Dept. Agr. Yearbook 1899, pp. 259-292, pls. 3*).—The author briefly reviews the investigations in the different States and in this Department upon the economic relations of various birds. An account is also given of the extent to which game birds are used, the collection of birds' eggs for food, the use of feathers and guano, measures for the destruction of injurious birds, preservation of beneficial birds, and the introduction of birds.

How some birds help the farmer, V. H. LOWE (*Trans. New York State Agr. Soc. and New York Bureau Farmers' Inst. Rpt. 1898, pp. 315-326, pls. 5*).—Notes on the economic relationship of the crow, blackbird, robin, Baltimore oriole, meadow lark, downy woodpecker, hairy woodpecker, brown creeper, chickadee, native sparrows, and cuckoos, with a short bibliography.

Some of the economic relations of birds and their food, F. E. L. BEAL (*Proc. New Jersey State Hort. Soc. 1899, pp. 104-129*).—This article presents a general discussion of the agency of birds in controlling the multiplication of certain injurious insects. The particular food habits of a number of birds are described, together with an account of those families of insects which contribute most extensively to the food of birds.

Birds, ANNIE M. GRANT (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 50-82, figs. 11*).—This paper is a popular discussion of the benefits conferred upon agriculture and horticulture by birds, with suggestions of measures for protection and preservation of birds.

Our native birds, D. LANGE (*New York: Macmillan Co., 1899, pp. 162, figs. 10*).—A discussion of the causes of the decrease in the number of birds and methods for protecting them.

How to encourage the nesting of insectivorous birds in fruit orchards, SCHWARZ (*Hessische Landw. Ztschr., 69 (1900), No. 1, pp. 6, 7, fig. 1*).—A description with illustration of a box for feeding such birds during the winter season.

A list of the insectivorous birds of New South Wales, A. J. NORTH (*Agr. Gaz.*

New South Wales, 11 (1900), No. 1, pp. 1, 2, pl. 1).—Notes on the habits of species of *Struthidea* and *Pomatostomus*.

An attempt to protect the green woodpecker, C. SARCÉ (*Belg. Hort. et Agr.*, 12 (1900), No. 3, pp. 42, 43).—Notes on the insectivorous habits of this bird.

Investigations on the stomach contents of the seed crow (*Corvus frugilegus*), M. HOLLRUNG (*Jahresber. Vers. Stat. Pflanzenschutz, Halle*, 10 (1898), pp. 11–28).—A detailed statement is made of the stomach contents of 324 seed crows, 11 hooded crows, and 5 jackdaws. The majority of these birds were killed during the summer season, but the conclusions to be drawn from a study of the stomach contents are favorable for the birds.

Oysters and disease, W. A. HERDMAN and R. BOYCE (*London: G. Phillips & Son*, 1899, pp. 60, pls. 8; *abs. in British Med. Jour.*, 1900, No. 2041, p. 338).—In this article the authors discuss, among other matters, the greening of oysters. The conclusion is reached that there are several distinct varieties of this phenomena. Some, like the green oysters of certain rivers of the Essex coast, are healthy, while others, such as Falmouth oysters, contain copper.

Eel worm in roses, B. D. HALSTED (*Florists' Exchange*, 12 (1900), No. 4, pp. 84, 85, fig. 1).—Brief notes on these worms, with the recommendation to heat the soil to 140° F. before planting.

Earthworms in the forest, E. HENRY (*Bul. Soc. Sci. Nancy*, 3. ser., 1 (1900), No. 2, pp. 23–34).—This article contains a brief historical account of the literature relating to the effect of earthworms upon the condition of the soil, and also brief observations upon their habits in the soil of forests. Notes are given on the action of earthworms in burying the various forest leaves and upon the apparent choice of kinds of leaves by the worms.

METEOROLOGY—CLIMATOLOGY.

Nile floods and monsoon rains (*Nature*, 62 (1900), No. 1608, pp. 391, 392).—This article discusses, on the basis of data furnished by the meteorological reporter to the government of India, the relation between the amount of the Nile floods and the abundance or deficiency of the southwest monsoon rainfall in India. The relationship was first suggested by Willcocks in a paper before the Meteorological Congress at the World's Fair in Chicago (E. S. R., 5, p. 1086). It is claimed that the observations which have been made "indicate that in at least four out of five seasons in which there was a partial failure of the rains in India there was a low Nile, and that generally the two countries are similarly affected by the meteorological conditions and the variations of those conditions. The causes of these variations are obscure and at present very imperfectly recognized."

Work of the meteorologist for the benefit of agriculture, commerce, and navigation, F. H. BIGELOW (*U. S. Dept. Agr. Yearbook* 1899, pp. 71–92, pls. 2).—This paper is devoted mainly to a history of the U. S. Weather Bureau and an account of its working, it being stated that "a consideration of the development of meteorological science in the United States, especially in its practical application to agriculture, commerce, and navigation, involves mainly a review of the United States Weather Bureau and its work." The topics treated include The organic laws establishing the weather service, the three epochs of meteorological service, a preliminary historical sketch of meteorology in the United States, the weather map, administration of the weather service, meteorological reports and storm warnings, instruction

in meteorology, means of instruction and information for the public, contributions of the Weather Bureau to meteorology, and latest views on the theories of the origin of storms.

Recent progress in weather forecasting, P. HOLDEFLEISS (*Fühling's Landw. Ztg.*, 49 (1900), No. 7, pp. 270-273).—This is a brief review of a paper by W. J. van Bebber on The scientific basis for forecasting the weather several days in advance, published at Hamburg in 1899.

Anemometer tests, C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 223*, pp. 18, pls. 2, figs. 5).—This paper, which is reprinted from the *Monthly Weather Review*, 28 (1900), No. 2 (E. S. R., 12, p. 119), "aims to give briefly the results of a limited series of experiments recently conducted by the writer to determine the law of action of a small anemometer employed on kites to record the motion of the wind in the free air. . . . The general question of anemometer testing is also very briefly discussed."

Meteorological tables, T. S. OUTRAM (*Minnesota Sta. Rpt. 1899*, pp. 575-587).—These tables give the monthly and annual mean temperature and precipitation for the year 1898 and 6 months of 1899, with departures from the normal for 62 stations in the State.

Meteorological observations, C. W. PETERSON (*Rpt. Dept. Agr. Northwest Territories, 1899*, pp. 5-14).—Tabular statements are given of (1) the total annual precipitation from 1883 to 1899, inclusive, at 8 stations; (2) total monthly precipitation during 1899 at 39 stations; and (3) the maximum, minimum, and mean temperature during each month of 1899 at 34 stations. "A brief summary of the records of the Dominion meteorological service of the temperature and precipitation conditions prevailing throughout the Northwest Territories during each month of the year" is also given. The meteorological stations (with voluntary observers) in the Territories now number 44.

General summary of meteorological observations in Mexico during 1899, E. E. SCHULZ (*Rev. Cient. Bol. Met.*, 3 (1900), No. 1-2, pp. 145-158).

Contribution to the study of the climatology of the Valley of Mexico, M. MORENO Y ANDA (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 14 (1899-1900), No. 9-10, pp. 353-360).—This is a summary of observations on barometric pressure during 15 years (1884-1898) at the Tacubaya Observatory.

AIR—WATER—SOILS.

A study of soil moisture, C. A. KEFFER and J. D. TINSLEY (*New Mexico Sta. Bul. 31*, pp. 16, fig. 1).—Incomplete records of moisture at depths of 6 to 9 in. and 21 to 24 in. in the soil of plats planted to corn and cultivated in different ways during the season beginning April 17 and ending October 5, 1899, are reported and discussed. The moisture determinations were made by the gravimetric method and by means of the electrical apparatus devised by the Division of Soils of this Department. Practically all types of soil texture, from adobe to pure sand, were represented in the plats used in this experiment. Consequently a great variation in the moisture content and requirements of the soils was observed. While the results are incomplete and not conclusive they indicate "the great variability in the character and moisture content of the alluvial soils of the Rio Grande valley."

"[They also indicate] the importance of maintaining a sufficient moisture supply for the continuous, uninterrupted growth of the crop—the great quantity of poorly developed corn in this field being assumed to be due to the check in the growth of the second planting, caused by drought; and of bringing all parts of a field to as nearly the same moisture holding capacity as possible by the application of correctives, preferably in the form of green crops, to be plowed under during active growth."

Soil moisture, H. H. NICHOLSON (*Nebraska Sta. Rpt. 1899, pp. 35-37*).—A brief account is given of a study of methods of determining the moisture content of soils, especial attention being called to errors in sampling. An apparatus devised for taking soil samples at different depths is described as follows:

"[It] consists of a 2 in. brass tube 24 in. long. In the side, 4 in. back from the cutting edge, a section is cut out and then fastened to the tube by a hinge joint. This pocket cover is held in place by a sleeve which screws down against a shoulder just above the cutting edge. To obtain a sample at a depth of 9 to 12 in., for example, the tube is driven down 12 in. into the soil and then withdrawn. The core of soil remains in the tube. The sleeve is unscrewed and slipped back and the cover raised. Three inches of the cylinder of soil thus exposed is cut out with a spatula and dropped into a tared box and weighed and dried. Results obtained thus far are highly encouraging."

The chemical and geological history of the atmosphere, J. STEVENSON (*Phil. Mag. and Jour. Sci., 5. ser., 50 (1900), Nos. 304, pp. 312-323; 305, pp. 399-407*).—This paper discusses "the question as to whether any notable change has taken place in the chemical composition of the atmosphere in the course of geological history." The author adduces evidence derived mainly from a study of the amount of carbonaceous and other oxidizable matter due to vegetation which is found on the earth to prove "that there was a time when there was no free oxygen on the earth."

Movements of ground water, B. S. LYMAN (*Jour. Franklin Inst., 150 (1900), No. 4, pp. 285-299*).—A critical review of reports on the principles and conditions of the movements of ground water, by F. H. King and C. H. Schlichter, which have already been noted (*E. S. R., 11, pp. 517, 519*).

Artesian wells, L. WOOLMAN (*Rpt. State Geologist of New Jersey, 1899, pp. 55-139*).—A record is given of size, depth, character of strata penetrated, quality of water supplied, etc., of 98 artesian wells, mainly in New Jersey, but including some in other States.

The influence of forests on soil moisture, drainage, and ground water, and the flow of springs, E. W. EBERMAYER (*Einfluss der Wälder auf die Bodenfeuchtigkeit, auf das Sickerwasser, auf das Grundwasser, und auf die Ergiebigkeit der Quellen. Stuttgart: Ferdinand Enke, 1900, pp. 51*).

Chlorin in the natural waters of the State, W. S. MYERS (*Rpt. State Geologist of New Jersey, 1899, pp. 141-148*).—Determinations of total solids and chlorin in 39 samples and detailed sanitary analyses of 18 samples of surface waters are reported. This data is being collected with a view to preparing a map showing the normal chlorin content of the potable waters of each locality in New Jersey.

The question of the hygienic importance of nitrites in drinking water, E. SCHAEER (*Ber. Deut. Chem. Gesell., 33 (1900), No. 8, pp. 1232-1236*).—The author agrees with Spiegel (*E. S. R., 12, p. 21*) that in the present state of our knowledge the determination of nitrites in water is neither positively nor negatively of decisive importance.

Soil investigations in the United States, M. WHITNEY (*U. S. Dept. Agr. Year-book 1899, pp. 335-346*).—This article discusses the influence of transportation facilities

on population and farm crops, early use of fertilizers, chemical investigation of soils, bacteriological investigation of soils, physical conditions and soil investigations, and important soil investigations and their utility. It is a review of progress in this line of investigation during the nineteenth century.

"Probably the most important immediate results of practical utility to be derived from these soil investigations are the mapping of large areas in important agricultural districts. In the irrigation districts these investigations point out any source of alkali which is to be feared, the cause of the accumulation, and give a basis for the intelligent underdrainage when necessary to remove the salts and seepage waters. In all cases the maps show the various types of soils, and the reports accompanying them explain the differences in these soils so far as possible, and describe their characteristics. The greatest value of these maps will be in the possibility of intelligent specialization. When a light loam is seen adjoining a heavier loam or clay the methods of cultivation or cropping should not be alike, and will not be when the farmers realize the importance of the differences in the properties of the soils. It is generally a waste of energy to attempt thus to compete, or use the same methods, or even to grow the same crops oftentimes on soils of such different texture. The safest and altogether most practical thing is to recognize the differences in the soils and the peculiarities of each; use each for the particular crop or class of crops best suited to the conditions; then attempt to improve each by the controlling factors, which are quite sure to be revealed in the experience of changing climatic conditions and the development of crops in the course of 2 or 3 years. The development of plants is a sure and safe guide generally to an experienced person as to the condition of the soil. This specialization is unquestionably developing in this country as a result of competition and of social conditions, and reliable and detailed soil maps will be the best possible basis for this purpose."

On marsh formation on the west coast of Schleswig and on the character of the reclaimed lands, BECKER (*Jour. Landw.*, 48 (1900), No. 2, pp. 123-145, figs. 2).—The formation and character of these lands are described and physical and chemical analyses and pot tests of samples of the soil are reported.

Dunes and their culture (*Deut. Landw. Presse*, 27 (1900), Nos. 40, pp. 499, 500, figs. 4; 44, p. 551, figs. 3).

FERTILIZERS.

Alfalfa as a fertilizer, B. C. BUFFUM (*Wyoming Sta. Bul.* 44, pp. 93-106, pls. 2).—This bulletin discusses briefly the fertilizer requirements of soils of arid regions, especially of Wyoming, and the value of alfalfa for increasing the nitrogen of the soil, improving the tilth, and destroying weeds; and gives the history of an acre plat on the Laramie Plains, one-half of which had been in alfalfa since 1893 and the other half in other crops. The whole plat was plowed in the fall of 1898 and seeded in the spring of 1899 to wheat, oats, and potatoes, one-half of each of these crops being on the alfalfa land and the other half on the part which had been under rotation with other crops. The main results obtained are summarized as follows:

"The value of alfalfa harvested from one-half acre of land for 5 years at Laramie was about \$50 more than the cost of producing it.

"The value of potatoes and grain from an adjoining half acre for 5 years was about \$44 more than the cost of producing at local prices.

"When the alfalfa land was plowed and planted to wheat it produced \$8 to \$12 more value in wheat per acre than the land which had grown potatoes and grain before.

"When alfalfa land was plowed and planted to oats it produced \$16 worth of grain more than land which had grown potatoes and grain before.

"When alfalfa land was plowed and planted to potatoes it gave \$16 worth more of potatoes per acre than was obtained from land which had grown potatoes and grain before.

"By growing alfalfa the above increase of yields and values were produced with absolutely no cost for fertilizing the land."

Nitrate of soda and sulphate of ammonia on marsh soils, CLAUSEN (*Landw. Wehnl. Schleswig-Holstein*, 50 (1900), No. 33, pp. 562-564, fig. 1).—Pot experiments with a soil containing 5 to 7 per cent of fine sand, 25 per cent of clay, and 2.5 per cent of calcium carbonate are briefly reported. The pots contained 5.5 kg. of soil. Oats was the crop grown. Nitrate of soda was applied May 26 at the rate of 1.3 gm. per pot, sulphate of ammonia May 9 and 10 at the rate of 1 gm. per pot. Similar experiments were made with beets in pots containing 16 kg. of soil. The superiority of the sulphate was evident during the growing period, and the yields of both oats and beets were decidedly larger on the pots receiving sulphate. These results indicate that on marsh soils containing a liberal supply of lime, sulphate of ammonia may with advantage be substituted for nitrate of soda, and confirm the wisdom of the practice common in Germany of using ammoniated superphosphates on such soils.

The basic constituents of crops, R. WARINGTON and E. DEMOUSSY (*Ann. Agron.*, 26 (1900), No. 5, pp. 246-257).—This is a translation and discussion by E. Demoussy of an article by R. Warington.¹

In this article the author attempts to show the relation between salifiable bases in the ash of plants and their nitrogen content, assuming that "if the whole of the nitrogen in a crop has been derived from nitrates and no subsequent loss of the bases of these nitrates has occurred we ought to find in the plant ash an amount of salifiable base equivalent to the nitrogen content in the crop." Applying this theory to a number of different crops it was found that the salifiable base actually present, as shown by average analyses, varied from 20 per cent to 92 per cent of the assumed nitrate base. Further investigation of this subject by means of pot experiments and analyses of more carefully selected material is suggested.

Change in weight of some artificial fertilizers on exposure to the air, L. VON WISSELL (*Jour. Landw.*, 48 (1900), No. 2, pp. 116-121). Fifty gram lots of Thomas slag, superphosphate, kainit, nitrate of soda, and ammonium sulphate were exposed to the air in the open and in a laboratory in flat porcelain dishes during different seasons of the year. The dishes were covered with perforated filter paper and were weighed almost daily (with the paper covers removed). There was a small increase in weight of the Thomas slag after a few days'

¹Agr. Students' Gaz., n. ser., 9 (1899), pp. 133-138.

exposure to the air, the weight remaining constant thereafter. The superphosphate increased or decreased in weight according to the temperature and the moisture of the air. Kainit was the most hygroscopic of the materials tested. In one instance its weight increased 31 per cent in 8 days. The weight of the nitrate of soda fluctuated with the temperature and moisture content of the air. In hot, dry weather it lost nearly all of its water, while in one case in damp weather it increased in weight 11 per cent. In case of ammonium sulphate the increase in weight was not very large.

Analyses of commercial fertilizers, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul.* 80, pp. 201-245).—This bulletin discusses the valuation and selling price of fertilizers, the usefulness of a fertilizer control, guaranties and brand names, sources from which plant food is derived, availability of organic nitrogen, and the selection and purchase of fertilizers; and reports analyses of 132 brands, representing 19 companies. This includes 86 analyses reported in previous bulletins of the station (*E. S. R.*, 12, pp. 226, 430). "Six-sevenths of the brands were up to or above guaranty, one-seventh fell short somewhat, and one-twentieth failed to furnish a commercial equivalent of their guaranties." While as a rule the quality of materials used in fertilizers was good, it was found that two-fifths of the brands contained no water-soluble nitrogen, and that sulphate of potash was found in but one-seventh of the brands examined, although claimed to be present in three-fourths. The average selling price of the fertilizers examined approximated \$28.73, the average valuation \$18.08. The average composition of the fertilizers was but slightly higher than last year. "Plant food is as cheap as it ever was; yet buying mixed goods on time is still a more costly method of getting plant food than is home mixing or buying on special order." A table compares the analyses of 133 brands for 5 years.

Fertilizer experiments on the action of Thomas slag and nitrate of soda as supplements to barnyard manure (*Fühling's Landw. Ztg.*, 49 (1900), No. 7, pp. 265-270, fig. 1).—Experiments with fodder beets, turnips, and cabbages on light marsh soil are reported. A decided benefit resulted from the addition of the phosphoric acid to the manure, but there was no evidence that the supplementary application of nitrate of soda was of any benefit except during the earlier stages of growth when the supply of available nitrogen in the soil was small.

Nitrate of soda or ammonia? P. WAGNER (*Hessische Landw. Ztschr.*, 70 (1900), No. 8, pp. 91-93).—A popular discussion of the relative fertilizing value of these two substances.

On phosphates, L. SCHUCHT (*Ztschr. Angew. Chem.*, 1900, Nos. 20, pp. 489-491; 21, pp. 512-515).—Discusses the occurrence, composition, and properties of the principal phosphates of the world.

Transformation of phosphates and potash salts in the soil, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, I, No. 18, pp. 633, 634).—This is a brief note on tables and charts prepared for the exposition at Paris, showing the manuring, culture, and yields in field experiments carried on by the experiment station of Est since 1892.

Attention is especially called to the total phosphoric acid and potash and that soluble in 1 per cent citric acid in the soils of the differently fertilized plats.

Analyses of commercial fertilizers, M. B. HARDIN (*South Carolina Bul.* 53, pp. 24).—This bulletin reports analyses of 176 samples of fertilizers collected during the season of 1899-1900, discusses the composition and valuation of commercial fertilizers, and gives regulations governing the sale of fertilizers in South Carolina and the text of the law providing for the free analysis of purchasers' samples of fertilizers, recently passed by the State legislature.

Analyses of commercial fertilizers, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul.* 79, pp. 189-198).—The results of analyses of 47 brands of fertilizers, representing 17 manufacturers, are reported.

Commercial fertilizers, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul.* 65, pp. 181-196).—This bulletin gives analyses and valuations of 140 samples of fertilizers registered for sale in West Virginia from January 1 to April 15, 1900, with a schedule of trade values of fertilizing materials, and the text of the State law relating to fertilizers.

FIELD CROPS.

Report of the agriculturist, T. L. LYON (*Nebraska Sta. Rpt.* 1899, pp. 15-22).—Brief summary of results obtained in soil tillage and cultivation experiments, in tests with barnyard manure and other fertilizers, and with sugar beets, grasses, forage crops, winter wheat, soy beans, and chicory.

Shallow cultivation has given the best results with corn, sugar beets, and chicory. With the 2 latter crops a portion of the land was mulched with coarse sand and no cultivation given after the crops were thinned. The portions of the crops so treated gave larger yields than when they were cultivated. The author believes that in years of ordinary rainfall in the region of the station, the only benefit from cultivation during the growing season is from the removal of weeds and the preservation of moisture by means of the soil mulch produced.

Harrowing oats in rows 6 in. apart has resulted in considerably increased yields. Refuse lime from sugar-beet factories was used on corn, sugar beets, and alfalfa. Only the alfalfa seemed especially benefited by the application. With this crop the refuse lime occasioned an increase of nearly 1 ton of hay per acre.

The leaf disease (*Cercospora beticola*) affecting beets was held in check by Bordeaux mixture. Hungarian brome grass (*Bromus inermis*) has given the greatest promise of the grasses tested. Out of 100 varieties of wheat tested, Turkey Red, Big Frame, and Currell and 3 Russian varieties proved hardiest.

Alfalfa as a hay crop, B. C. BUFFUM (*Wyoming Sta. Bul.* 43, pp. 47-91, figs. 8).—Results are reported of investigations at the station and elsewhere in the State on the culture of common and Turkestan alfalfa. The growth of alfalfa on alkali soils and the irrigation of alfalfa are discussed and some figures given bearing on these 2 factors in alfalfa growing in the State.

Alfalfa has been successfully grown at the station which is located at an altitude of more than 6,000 ft. Directions are given for the preparation of the land, time and method of seeding it at this altitude, cutting, and curing. Seeding without a nurse crop is advised when difficulty in securing a good stand is met with. In tests at the station an average decreased yield of one-half ton per acre followed the seeding of alfalfa with oats for each of 3 succeeding years. The average yield of alfalfa on different plats for from 2 to 5 years has varied from 4,950 lbs. to 7,161 lbs. per acre. At altitudes below 6,000 ft. the average yield has been: At Lander, from 7,000 to 8,000 lbs. per acre; Sheridan, 10,600 to 16,800 lbs.; Wheatland, 10,380 to 20,402 lbs. At Laramie, Turkestan alfalfa has yielded at the average rate of 7,625 lbs. per acre, as compared with an average yield for 3 years of 6,030 lbs. of common alfalfa grown on plats under similar conditions. The Turkestan alfalfa has proven especially hardy at the station, having successfully withstood the severe winter of 1898-99, without apparent winterkilling, when all plats of common alfalfa were more or less injured. The author states that the principal cause of winterkilling of alfalfa seems to be the freezing of water around the crown of the plant.

Alfalfa was grown on plats containing different percentages of alkali salts. The following table shows, in a measure, the tolerance of this plant for alkali:

Tolerance of alfalfa for alkali.

	Total salts.	Sodium chlorid.
	<i>Per cent.</i>	<i>Per cent.</i>
Alfalfa killed:		
Salts in first 6 in. of soil.....	0.620	0.029
Salts in soil from 6 in. to 1 ft. deep.....	.792	.053
Alfalfa thrifty:		
Salts in first 6 in. of soil.....	.034	.000
Salts in soil from 6 in. to 1 ft. deep.....	.270	.003

Irrigation after alfalfa is cut and late fall irrigation are advised. A table is given showing the number of times the alfalfa plats at the station were irrigated, date of irrigation, and the amount of water applied each time. The average amount of water used on alfalfa for the season would cover the ground 2.22 ft. deep.

Dodder is noted as one of the serious foes of alfalfa in Wyoming. Plowing alfalfa under and cultivating the land for a year or two in corn, potatoes, and the like is recommended. The experience of farmers in different sections of Wyoming who have had experience in the growing of alfalfa is noted, some letters being quoted.

Some of the conclusions of the author relative to alfalfa culture in Wyoming are as follows:

"Alfalfa succeeds in all parts of Wyoming under 8,000 feet altitude where it can be irrigated, and makes more fodder to the acre than any other hay plant yet introduced. . . .

"At high altitudes alfalfa requires careful treatment to secure a good stand and become well established. Heavy seeding and planting with the press drill are recommended.

"Two seasons are required to put the alfalfa into good producing condition on the Laramie Plains. . . .

"Alfalfa will not grow on wet land where the ground water stands as near the surface as 1 or 2 ft. . . .

"Alfalfa grows better where there is some alkali salt in the soil, but will not stand more than 1 per cent of our common white alkali in the first 6 in. of soil. It should not be planted where there is enough alkali to form white incrustations on the surface of the soil during any part of the year."

Corn culture, C. W. BURKETT (*New Hampshire Sta. Bul. 71, pp. 47-53, figs. 3*).—Methods of culture, effect of witch grass in growing corn, and depth of plowing in reference to corn production were the problems investigated in this experiment.

Methods of cultivating corn (pp. 47-53).—Certain corn plats were given no cultivation, others 5, and others 14 cultivations. Some of the plats were cultivated deep and others shallow. The results obtained in each case are tabulated and discussed, and a summary given of deep *v.* shallow cultivation experiments with corn at 17 experiment stations. On the plats not cultivated the weeds grew luxuriantly and the yield was reduced to 17.1 bu. of shelled corn per acre. The plats cultivated shallow 14 times yielded at the rate of 80.6 bu. of shelled corn per acre; cultivated 5 times shallow, the yield was 79.1 bu.; and cultivated 5 times deep, 69.7 bu. per acre. The amount of stover produced in each instance stood in about the same ratio as the grain production. The plat which had received a mulch averaging 3 in. in thickness of old swamp hay and given no further attention during the remainder of the season, yielded at the rate of 56.1 bu. of shelled corn per acre. The mulch was not sufficient to keep all of the weeds down. In the author's summary of the results of deep and shallow cultivation experiments carried on at other stations it is shown that out of 56 tests 36 were in favor of shallow culture, 12 in favor of deep culture, and 8 were inconclusive.

Effect of witch grass on corn production (pp. 53-55).—In this experiment witch grass was allowed to grow in the drilled rows of corn on certain plats which were cultivated but one way. Other plats were similarly cultivated except that the witch grass was removed from between the hills with a hand hoe. The yield of the hoed corn was at the rate of 81.6 bu. per acre, and of the unhoed 61.4 bu. per acre. In this experiment the increased yield of both stover and grain paid many times over for the extra labor of hoeing.

Effect of depth of plowing on yield of corn (pp. 56-58).—Plats of corn land were plowed in the fall 3, 5, 7, and 9 in. deep, respectively. The plats were similarly prepared in the spring and planted to Leaming corn. No difference was seen in the growth of the corn on the different plats until about the middle of the season when the deeper-

plowed plat showed a more vigorous and stronger growth. At the time the corn was put in the silo the plat plowed 3 in. deep yielded 14.2 tons of fodder per acre; 5 in. deep, 26.2; 7 in. deep, 29.4; and 9 in. deep, 28.2 tons per acre. It is concluded from this experiment that for a deep soil deep fall plowing is preferable to shallow plowing for corn. With impoverished soil, deep plowing can not be practiced. If the soil be shallow, it should be gradually deepened by subsequent plowing.

Results of experiments on cotton in Alabama, P. H. MELL ET AL. (*Alabama College Sta. Bul.* 107, pp. 181-423, pls. 23, figs. 3).—This bulletin was prepared by the station for the Paris Exposition, and covers the following subjects: Varieties, culture, manuring, chemistry, and diseases of cotton; the improvement of cotton by hybridization and by selection, and the climate of the cotton belt. Thirty-seven previous bulletins on the different phases of cotton culture have been published by the station. The present bulletin embodies the experience of the station in its study of cotton culture up to the present time, covering a period of 16 years. Such conclusions to date or such additional matter as has not been previously recorded will be noted.

The best average record of all varieties tested 4 or more years up to the present time has been made by Truitt and Peterkin, the yield of lint cotton of these 2 varieties for 7 years being at the average rate of 425 lbs. for the former and 417 lbs. for the latter per acre.

For the purpose of classification, 70 varieties were studied comparatively in 1899, and a provisional classification of varieties made.

Results of fertilizer experiments at the station have shown that cotton-seed meal and nitrate of soda are practically equally valuable as sources of nitrogen for cotton. Cotton seed and cotton-seed meal were about equally effective. In 79 per cent of the tests with stable manure *v.* cotton seed the yields were greater with stable manure. In 1898 cotton, cowpeas, and velvet beans were grown on contiguous plats. The cowpeas and velvet beans were picked and removed from the field and all the plats plowed in March, 1899, and planted to cotton. The yield of seed cotton per acre was 1,533 lbs. following cowpeas, 1,373 lbs. following velvet beans, and 837 lbs. following cotton. In 3 other experiments the average increase of seed cotton per acre, due apparently to the plowing under of velvet beans, was 660 lbs., a gain of 72 per cent as compared with the average yield of plats where the preceding crop had been cotton. In a cooperative experiment conducted under unfavorable conditions, the average increase of seed cotton per acre occasioned by turning under cowpeas was 125 lbs. An average increase of 32 lbs. of seed cotton in 1899 was attributed to the residual effect of applying 720 lbs. of rotted cotton seed in 1898. It is believed that the average yield of cotton per acre in Alabama might be increased at least 50 per cent through the general use of legumes as fertilizers.

As to the comparative merits of acidulated and raw phosphate for fertilizing cotton and the residual effects of the same, the summarized results of all the experiments made under the direction of the station and bearing on this point seem to abundantly demonstrate the superiority of the acid phosphate.

The use of potash as a factor in controlling the black rust in cotton is summarized as follows: "Not only kainit but other soluble forms of potash, as the muriate, sulphate, and silicate may, under suitable atmospheric conditions, restrain the spread of black rust. The minimum amount required to exert a notable rust-restraining influence is not yet determined, but is between 50 and 100 lbs. of kainit per acre, and apparently nearer the latter figure."

Results of experiments in composting such materials as cotton seed, fine stable manure, cotton-seed meal, and phosphate, taken as a whole, offer no arguments in favor of the practice. Fractional applications of fertilizers have not proven advantageous. The best time for applying fertilizers is believed to be before the seed is sown. The results of cooperative experiments have shown that practically all the cotton soils of Alabama, except the central prairie region, are greatly benefited by the addition of acid phosphate. Cotton-seed meal is desirable on nearly all soils in the State except new lands and soils containing considerable vegetable matter. Kainit is less frequently needed than either acid phosphate or cotton-seed meal. It is most needed in the southern part of the State and on soils especially liable to black rust. Fertilizer formulas suitable for different sections of the State are tentatively suggested.

The section of the bulletin treating of diseases of cotton considers the following subjects: Root knot, sore shin or damping off, cotton wilt, rust, anthracnose of the stem, red rust, leaf blight, cotton mildew, angular leaf spot, cotton-boll rot, anthracnose of the boll, and shedding of bolls. Sulphur used at the rate of 16 lbs. per square rod seemed to have no beneficial effect in freeing the soil from nematodes causing root knot. In pot experiments injections into the soil of carbon bisulphid seemed to be beneficial for this purpose, but satisfactory results were not secured with it in field tests. Unpublished investigations of C. F. Baker are given as showing that the probable cause of the cotton-boll rot (at least in the case under investigation) was primarily due to the puncture of the boll by one of the small hoppers, known as "sharp shooters," after which it was attacked by various species of saphrophytic fungi which fed on the broken-down tissue of the boll. A number of these fungi were isolated, but inoculation experiments with them during dry weather failed to produce the disease. The bibliography of cotton diseases contains 47 references. A list of 64 varieties and species of fungi, recorded as growing on cotton, is also given.

Original determinations are reported of the composition of the cotton plant at 5 different stages of growth. The following table shows the composition of different parts of the entire mature plant:

Complete analysis of the entire mature cotton plant.

The fertilizer requirements of cotton as determined by the analysis of the plant are discussed, and a summary is given of the effect on butter of feeding cotton seed and cotton-seed meal (E. S. R., 3, p. 6).

The southern or cow pea in Delaware, A. T. NEALE and W. H. BISHOP (*Delaware Sta. Bul.* 46, pp. 3-9, 12-24).—Following a popular comparison of the relative merits of crimson clover and cowpeas for culture in Delaware are given some results obtained in cultural, fertilizer, and variety tests with this crop. The actual cost of raising and ensiling 1.37 acres of mixed Whippoorwill and Black cowpeas at the station was at the rate of \$17.92 per acre (including a land rental of \$5 per acre) or \$1.36 per ton of silage grown. Analysis showed that about 5.25 tons of the silage contained more protein, fat, and carbohydrates than a ton of ordinary bran.

The botany of the cowpea is touched upon and some results obtained in previous fertilizer tests with this crop are (E. S. R., 6, p. 802) given. The varieties most suited for cultivation in Delaware are Whippoorwill, New Era, Black, Clay, Unknown, and Black-eyed. These varieties are described and the characteristics of each noted. Twelve other early varieties and 28 late varieties tested at the station are also briefly characterized. New Era has given the largest yields of any of the varieties tested at the station, the average for 2 years being 24,218 lbs. per acre.

Experiments were made to determine the effect upon plant development of cowpeas due to geographical differences in the source of the seed and to variation in the amount of seed planted per acre. The seed of a number of varieties was obtained from nearly every Southern State and grown at the station. No evidence was obtained in these tests that seed grown in the far South required any longer season for maturing a crop at the station than the same variety grown some hundreds of miles farther north; and there seems to be some evidence that Delaware grown seed is as good for crop production as that obtained farther south. In 1898 seeding Whippoorwill peas at the rate

of 2 pk. per acre, yielded better results than 1 pk. per acre and about as good results as 3, 4, or 5 pk. per acre.

The relation of the weather to cowpea production is discussed. In 1898 the average production of 5 different varieties of cowpeas was about one-fourth larger than in 1897. In 1898 the rainfall for the months of June to October, inclusive, was 5.35 in. more and the average temperature 2.4° F. higher than for the same months in 1897, and it was thought the increased yields of cowpeas in 1898 might have been due to these causes.

A two year's test of 128 varieties of grasses and forage plants, T. L. LYON (*Nebraska Sta. Rpt. 1899, pp. 122-171*).—A report is given on the results of 2 years' testing of 128 varieties of grasses and forage-plant seeds, which were contributed to the station by the Division of Agrostology of this Department. The collection was composed almost entirely of seeds of native or foreign wild grasses and of cultivated foreign grasses, there being very few of the grasses ordinarily cultivated in that region. The test has continued through 3 summers and 2 winters, and while not long enough time has elapsed to indicate with any degree of certainty the value of any of these grasses for this region, it is demonstrated that a large number can not be successfully grown. Of the number tested only 16 have survived the entire period of the test, as follows: *Agropyron repens*, *A. tenerum*, *Arrhenatherum elatius*, *Bromus ciliatus*, *B. inermis*, *B. tectorum*, *B. unioloides*, *Elymus canadensis*, *E. glaucifolius*, *E. virginicus*, *Eragrostis trichodes*, *Festuca elatior arundinacea*, *F. ovina duriuscula*, *F. ovina elatior*, *F. ovina sulcata*, *F. elatior pratensis*, *Hordeum pratense*, and *Stipa robusta*.

The influence of chlorin and other compounds in crude Stassfurt salts on the composition and yield of potatoes, B. SJOLLEMA (*Jour. Landw.*, 47 (1899), No. 4, pp. 305-357).—Investigations were made on the effect of chlorin compounds on the composition and yield of potatoes, with special reference to those found in crude Stassfurt salts. The article contains, besides an account of the author's experiments, a review and discussion of the results obtained by other investigators along the same lines. Potassium chlorid, sodium chlorid, and magnesium chlorid lowered the starch content materially, each to about the same extent. The reduction was greatest in the case of varieties relatively rich in starch. New varieties and those making a heavy growth of tops were especially sensitive to chlorids.

Investigations on the chlorin content of potato tubers showed that it is increased by the application of chlorids in the spring. With the higher chlorin content of the tuber is associated a higher water content and a lower starch content. The potash content of the entire tuber was about the same whether the chlorid or the sulphate was applied, but the potash content of the dry matter was much higher in

the former case—that is, with chlorin a less amount of organic matter had been elaborated. This higher percentage of potash was present entirely in the original form of potassium chlorid, which is, in the author's opinion, the cause of the increased water content of potatoes grown with it. It is suggested that the low starch content of the tubers may be accounted for by the presence in the sap of the relatively large amount of potassium chlorid, thus interfering in some way with the formation of starch. The relation of starch content to potash content was found not to be uniform in different varieties. Some required a larger amount of potash to manufacture a given amount of starch than did others.

Experimental inquiries were made with regard to the substitution of soda or magnesia for potash. Soda was never found in the tubers, at least not in any considerable quantity, though it was found in the tops of plants to which it had been applied. Magnesia was found in small quantities, about one-twentieth to one-tenth of the amount of potash present, but in the case of neither soda nor magnesia did addition of these elements diminish the potash requirements of the plant.

The yield of the tubers was only slightly reduced by application of potassium chlorid, but was much reduced by additions of magnesium chlorid or sodium chlorid. When either of the latter elements were applied to a plat which had already received liberal applications of potassium sulphate, the yield was considerably less than on a check plat which had received no fertilizer at all, showing that the good effect of the sulphate of potash is more than counteracted by the ill effect of these chlorids; but magnesium sulphate and sodium sulphate produced no unfavorable effect. On the contrary, experiments indicated that these salts slightly increased the yield and starch content of potatoes, and decreased the potash content of the tubers.

Sugar-beet investigations in 1899, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul. 64, pp. 155-176, map 1*).—The experiments with sugar beets at the station in 1899 involved a study of the influence of different fertilizers and of lime upon the sugar content and purity of the juice, different dates of planting and harvesting, tests of varieties, and cooperative culture experiments carried on with farmers throughout the State.

Excessively wet weather interfered with the fertilizer and lime experiments, but the results show that the stand of beets was practically the same on limed and unlimed plats. When lime was used alone on the plats there was a slight improvement in the sugar content and purity of the juice; used with commercial fertilizers or barnyard manure, it seemed to have the opposite effect. Stable manure seemed to increase the impurities in the juice; while the use of acid phosphate regularly gave the highest coefficients of purity.

In the variety tests scarcely any difference was found between the

relative values of Vilmorin, Mangold, Zehring and Kleinwanzlebener. Beets planted May 29 contained more sugar in the juice and juice of purer quality than beets planted either before or after that date. Not much variation occurred in the sugar content and purity of the juice of beets harvested at different dates between September 18 and November 9. Analyses and other data, such as dates of planting and harvesting, character of soil and of the fertilizers employed, etc., are given for 155 samples of sugar beets grown by as many different farmers throughout the State. The average weight of the capped beets grown was 14.9 oz., sugar in the juice 12.77 per cent, purity of the juice 76.15 per cent. The result of the season's work is considered favorable and the work will be continued.

Sugar cane—field and laboratory results for ten years, W. C. STUBBS (*Louisiana Stas. Bul.* 59, 2. ser., pp. 284-337).—This bulletin covers experimental work on the preparation of the soil, kind and quantity of cane to plant, proper fertilizers, and rational modes of cultivation. Attention is called to drainage as the first and most important essential in the preparation of the soil. Surface drainage is usually practiced in Louisiana. The merits of tile drainage are pointed out; but owing to the filling of the tiles by silt natural conditions are against its success in the locality.

During the 10 years' work at the station, foreign varieties of cane from nearly every sugar-producing country on the globe have been tested. Owing to the great difference in climate, the trials have not been satisfactory. The trials of seedlings are much more promising, and 3 such have been found of value.

In trials covering 6 years of plant and first and second year stubble for seed, purple plant has given slightly the best results as regards sugar content, while striped first-year stubble has given the largest yield in tonnage. When the results of both purple and striped varieties are combined, first-year stubble leads in tonnage, followed by second-year stubble. The inference drawn from the results of this work is that good stubble cane is fully the equal, if not the superior, of plant cane for seed.

It is estimated that one-sixth of the entire crop of cane in the State is used for planting. Experiments carried on for 13 years to test the availability of the less valuable upper third for this purpose are summarized, showing the results of chemical analyses of cane grown continuously from tops, middles, and butts. The results show but little difference as regards the value of the different portions of the cane for propagation, and the use of the upper third of the cane, which possesses little or no sugar value, but serves rather to increase the molasses output, is recommended from an economical standpoint.

In trials to determine the influence of planting large, medium, and small canes, selected continuously from plantings of large, medium, and small canes, respectively, the results show diminished yields from

using small, inferior stocks, and the conclusion is reached that it will be most profitable to plant large, strong, and vigorous canes for seed.

The composition of the roots, stalks, leaves, and tips of Louisiana sugar cane was investigated, with the following result:

Analyses of sugar cane (water-free materials).

	Proportion of whole plant.	Organic matter.	Ash.	Nitrogen.	Phosphoric acid.	Potash.	Lime.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Purple cane, cut November 12:							
Roots.....	4.50	90.882	8.624	0.494	0.279	0.273	0.400
Stalks.....	57.50	97.076	2.665	.259	.248	.289	.124
Leaves.....	23.13	86.567	12.969	.464	.190	.453	.845
Tops.....	14.87	88.170	10.773	1.057	.203	.545	.566
Striped cane, cut December 23:							
Roots.....	4.70	90.645	8.849	.506	.308	.573	.361
Stalks.....	56.82	96.728	3.055	.217	.302	.578	.144
Leaves.....	26.31	84.690	14.853	.457	.214	.934	.864
Tops.....	12.17	87.335	11.592	1.073	.564	.696	.415

The roots and stubble of cane are usually left in the soil, but it is a common practice in Louisiana to burn the tops and leaves. "A ton of purple cane as grown in Louisiana with its accompanying trash burnt in the field will thus remove 2.98 lbs. of nitrogen, 1.04 lbs. of phosphoric acid, 1.22 lbs. of potash, and 0.52 lb. of lime. A ton of striped cane, under similar conditions, will remove 2.38 lbs. of nitrogen, 1.30 lbs. of phosphoric acid, 2.34 lbs. of potash, and 0.58 lb. of lime."

The results of extended nitrogen, potash, and phosphoric acid experiments with sugar cane are given in detail. Earlier work with these fertilizers has been previously noted (E. S. R., 7, p. 678). Nitrogen not to exceed 48 lbs. per acre has been found profitable, and the best results followed when it was used in combination with phosphoric acid and potash. Sulphate of ammonia was found to be the best form of nitrogen for this crop, with cotton-seed meal a close second, followed by fish scrap, nitrate of soda, and tankage, in the order named. The increased cost of sulphate of ammonia in the local markets does not, in the opinion of the author, justify its use over cheaper forms. Data as to the amount of fertilizers applied and removed from plats devoted to sugar culture for 10 years are given.

In the fertilizer test with phosphoric acid for cane, small applications, not exceeding 36 lbs. per acre, were found most profitable. The soluble forms gave better results than the insoluble. Applications of from 200 to 300 lbs. of phosphoric acid are considered sufficient for a good average crop at the station. Tests of the different potash salts showed that this element was not needed in the station soils.

With regard to the effect of the different fertilizers on the sugar content the author states that heavy applications of nitrogenous fertilizers applied late in the spring tend to produce immature canes low in sugar content. Nitrogen should, therefore, be applied early in the growth of the cane. Neither potash nor phosphoric acid by itself has an influence on the sugar content, but when used with nitrogenous

fertilizers they cause a more rapid growth and a quicker maturity of the cane.

In 1894, and every year since, experiments have been carried on in making 1, 2, and 3 applications of an equal amount of nitrogen in the form of nitrate of soda and sulphate of ammonia. The results have been contradictory and no conclusions are drawn.

In a comparison of deep and shallow cultivation of cane with plows and cultivators, respectively, better results were obtained by shallow cultivation with cultivators. The author believes that, should every planter adopt the method of shallow cultivation of his soil after thorough preparation, the yield of cane would be increased in the State from 5 to 10 tons per acre.

Condensed tables of the weather record of 1897, 1898, and 1899 are given.

Work of the Hawaiian Experiment Station, 1899, W. MAXWELL (*Honolulu: Hawaiian Gazette Company, 1899, pp. 36*).—This report covers results obtained during the year in fertilizer, irrigation, variety, and seedling experiments with sugar cane. In the fertilizer experiments sulphate of potash and double superphosphate were used alone, together, and combined with different forms of nitrogen. Two varieties of cane, Rose Bamboo and Lahaina, were used, the experiment being thus carried out in duplicate. The yields of cane, leaves, and sugar per acre, and the composition of the cane and leaves as regards mineral matter and nitrogen for each variety grown, are shown in tabular form, and the results discussed. In no case in these tests has the use of phosphoric acid resulted in increased yields of sugar. The yields when potash or nitrogen was used were considerably increased, and to about an equal extent. When these elements were used together still larger returns were obtained.

An analysis is given of the sugar-cane soils of the station, and the percentages and total amount of the different elements and acids immediately available to a depth of 15 in. are shown. The available amounts of the 4 most vital elements were as follows: Lime, 37,669 lbs.; potash, 25,419 lbs.; nitrogen, 6,519 lbs.; and phosphoric acid, 45,937 lbs. The amount of these elements removed by the crop grown and the total yield of dry matter of the crop are shown in the following table:

Yield of dry matter in sugar cane and the amount of vital elements removed per acre.

	Yield of of dry matter.	Removed per acre.			
		Lime.	Potash.	Phosphoric acid.	Nitrogen.
Rose Bamboo:	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Cane	47,632	71	258	83	133
Leaves	52,800	301	882	81	279
Lahaina:					
Cane	44,403	50	121	51	119
Leaves	52,620	262	807	69	221

The great value of returning to the land partially rotted trash (leaves and tops) and plowing under rather than burning is pointed out. If the mud press-cake and molasses are applied to the land, one-fifth of the potash and one-third of the nitrogen removed in the cane is also saved.

In the irrigation tests 20 plats were regularly irrigated, receiving from 46.5 to 48 in. of irrigation water, and 8 others received no irrigation whatever. The average yield of sugar on the 20 irrigated plats was 24,755 lbs. per acre, and on the unirrigated plats, 1,600 lbs. The rainfall during the growth of the cane was 46.56 in., most of which fell during the colder months. Some results obtained in overirrigation are given and the evil effects of this practice are pointed out.

Experiments in testing 13 varieties of cane and in planting 1 and 2 continuous cut and uncut canes in the row, and 1-eye pieces 6, 12, and 18 in. apart, are under way and are briefly reported upon. Some results obtained in planting 1 and 3 eye pieces of plant cane 11 months old are given, showing that "1,901 pieces of cane, bearing 1,901 eyes, produced relatively as many canes as 2,411 pieces of cane bearing 7,233 eyes. Out of the 7,233 eyes, 4,697 died." The results lead the author to urge experiments by planters in the use of less seed than is usually planted.

The results of some analyses by the aspartic-acid method of soils yielding from 1 to 4 and from 5 to 10 tons of sugar per acre are tabulated, and some notes are given on the value of lime in sugar soils.

Important problems in plant breeding, W. EDLER (*Landw. Wechnbl. Sachsen*, 2 (1900), Nos. 35, pp. 303, 304; 36, pp. 310, 311).—Some of the more important points to be observed in the breeding of a number of the more prominent cereal and root crops are discussed.

Grain breeding, T. MANSHOLT (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 8, pp. 296-299; 9, pp. 327-334).—A discussion of the principles and methods involved in the improvement of grains by selection, etc.

The effect of size of seed on the crop, T. H. MIDDLETON (*University College of Wales Rpt. 1899*, pp. 68-70).—Wheat, oats, and beans were used in this experiment and large and small seed of each crop planted. The most striking results were secured with wheat. The yields obtained from the large seed were almost double those obtained from the small. The difference was less marked with oats. With beans practically the same results were secured with small as with large seed.

Field experiments, J. A. MURRAY and T. H. MIDDLETON (*University College of Wales Rpt. 1899*, pp. 3-26, 31-42).—Results are given of a number of cooperative experiments with fertilizers on grass lands, potatoes, and root crops.

Field experiments (*Bd. Agr. [London] Rpt. Agr. Education, 1899-1900*, pp. 37-42, 45-71, 74-89, 91-96, 99-107, 110-113, 117-124, 126-133).—The experiments reported have been carried out at eight different collegiate institutions. They consist of fertilizer experiments with swedes, potatoes, hops, mangolds, grass lands, and permanent pastures; seeding experiments with alfalfa and sainfoin; and rotation experiments. A number of the fertilizer experiments reported have been noted from other sources.

Farm experiments at Dalmeny (*Farm and Home*, 19 (1900), No. 969, p. 294).—A semiofficial summary is given of the results secured in the experimental work being carried out on Lord Roseberg's farm. An application of 4 cwt. of ground lime yearly has given better results than where much larger amounts have been

applied only at long intervals. Heavy applications of lime have been useful in controlling the finger-and-toe disease of turnips, but are considered to have a prejudicial effect on nitrifying and other advantageous soil organisms.

Methods of applying fertilizers, BERTHAULT (*Ann. Agron.*, 26 (1900), No. 9, pp. 417-430).—Broadcasting, applying in drills or in small amounts about each plant, etc., are considered for a number of crops.

Experiments with manures (*Farmers' Gaz.*, 59 (1900), No. 39, p. 753; *Agr. Gaz. [London]*, 52 (1900), No. 1394, p. 181).—Results secured in the use of different amounts of city manure, in the substitution of commercial fertilizers for a part of the city manures employed, and in the use of commercial fertilizers alone for growing certain vegetables and farm crops are given.

Culture of textile plants, G. D'UTRA (*Rev. Agr. Réunion*, 6 (1900), Nos. 60, pp. 241-248; 61, pp. 281-290).—Discussion of the culture, fibers, and manufacture of different textile plants.

Azof barley (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 6, pp. 322-324).—This barley was tested by a number of farmers to determine its merits as a forage crop. The results reported are somewhat contradictory.

Notes on cereals, T. H. MIDDLETON (*University College of Wales Rpt. 1899*, pp. 61-67).—The characteristic differences between young oat and barley plants, barley and wheat plants, wheat and rye plants, and wheat and oat plants are given, together with the distinguishing characteristics of a large number of varieties of oats.

Report on tests of deep and shallow plowing for corn (*Nebraska Sta. Bul.* 64, pp. 94-97).—Of reports on tests of deep and shallow plowing for corn from 16 correspondents living in different sections of the State, 9 show an increased yield of corn resulting from deep plowing, 4 no difference in yield from either deep or shallow plowing, and 3 an increased crop from shallow plowing. Relative to the effect of drought on the corn on the shallow and deep plowing, 8 correspondents report that the corn suffered more on the shallow plowing. In 5 cases there was no difference and in 3 cases the corn on deep-plowed land suffered more.

Introduction of American varieties of maize, G. VALDER (*Agr. Gaz. New South Wales*, 11 (1900), No. 9, pp. 782-785).—Nine varieties of corn were imported from the United States and distributed to farmers in New South Wales. The present article tells of the growth of the corn and includes some notes on the different varieties by growers. It has been noticed that the grain has been considerably improved since it has been grown in New South Wales. It is larger, well developed, and has a much better appearance for market purposes.

Rescue grass (*Bromus unioloides*), F. LAMSON-Scribner (*U. S. Dept. Agr., Division of Agrostology Circ.* 26, pp. 4, fig. 1).—A brief description with notes on the history, cultivation, use, and feeding value.

Analyses of forage crops, H. H. NICHOLSON (*Nebraska Sta. Rpt. 1899*, pp. 40-42).—Analyses (food constituents) are given for green, air-dried, and water-free *Bromus inermis*, oats and field peas, cowpeas and millet, sorghum, and alfalfa.

Succulent forage for the farm and dairy, T. A. WILLIAMS (*U. S. Dept. Agr. Yearbook 1899*, pp. 613-626, pls. 2).—The topics, historical and popular, discussed under the above heading are early forage conditions in the United States, place of succulent forage crops on the farm, growth of the practice of soiling in the United States, temporary pastures, history of the practice of ensiling, value of silage as a forage for stock, and the best crops for succulent forage. Under the latter heading, a number of the more important forage crops grown in this country are discussed.

Hemp (*Cannabis sativa*), S. S. BOYCE (*New York: Orange Judd Co.*, 1900, pp. X+112, figs. 13).—"A practical treatise on the culture of hemp for seed and fiber, with a sketch of the history and nature of the plant." The work takes up the history, botany, and chemical composition of the hemp plant and its culture in Europe and America. In the discussion of its culture in the latter country methods of retting and preparing the fiber and machinery for handling hemp are discussed.

Winter oats for grain and pasture (*Rural New Yorker*, 59 (1900), No. 2637, p. 543).—The successful culture of winter oats when seeded in August at the Delaware Station are reported by A. T. Neale. The oats bore from 30 to 50 berries per stalk and the yield was between 7 and 8 tons of green forage per acre.

On the origin and variability of the potato, E. ANDRÉ (*Rev. Hort.*, 72 (1900), No. 19, pp. 542, 543).—The adaptation of the potato to great variations in climate and soil and its variability in such locations are pointed out and some notes given on the growth of potatoes in Colombia and Ecuador. Some suggestions are added relative to the introduction and improvement of native South American and Mexican potatoes.

Potato growing experiments (*Queensland Agr. Jour.*, 7 (1900), No. 3, p. 215).—The summarized results of some fertilizer and cultural tests with potatoes are given. The use of 20 tons of barnyard manure resulted in the largest yields and tubers of the best cooking qualities. Sprouted seed tubers gave better yields than nonsprouted.

Trials of potatoes at the Wagga Experiment Farm, G. M. McKEOWN (*Agr. Gaz. New South Wales*, 11 (1900), No. 9, p. 786).—Data as to the yields obtained in tests of 10 varieties.

The effect of different potash salts on the composition and yield of potatoes, T. PFEIFFER (*Landw. Vers. Stat.*, 54 (1900), Nos. 5-6, pp. 379-385).—Work along this line by the author has been previously noted (*E. S. R.*, 10, p. 140). In the present instance magnesium chlorid used in connection with potassium sulphate decreased the percentage of starch in varying amounts in 4 varieties of potatoes. Fresh tubers which had been fertilized with chlorid of potash contained about 0.12 per cent of chlorin, while those fertilized with sulphate of potash contained about 0.05 per cent.

The influence of manures on the quality of potatoes, J. W. PATERSON (*West of Scotland Agr. Soc. Bul.* 4, pp. 27-35).—The quality of potatoes as affected by different commercial fertilizers and barnyard manure was investigated. In 12 out of 16 cases the use of barnyard manure injured the quality of the potatoes. The potatoes showing the highest starch content had been fertilized with a mixture consisting of 672 lbs. of superphosphate, 224 lbs. of sulphate of ammonia, 112 lbs. of nitrate of soda, and 224 lbs. of sulphate of potash per acre.

Indian millets or sorghums grown at Wollongbar, H. V. JACKSON (*Agr. Gaz. New South Wales*, 11 (1900), No. 9, pp. 759-763, figs. 36).—Notes on the cultivation of sorghum in India with data on the development of 45 varieties imported from there and grown in New South Wales.

Sorghum for sirup, G. W. SHAW (*Oregon Sta. Bul.* 62, pp. 3-6).—A number of varieties of sorghum were distributed by the station in some of the districts of Oregon which seemed most suited to the culture of this crop. Some data as to the growth of the stalks and the sugar content of the juice of samples from 28 different localities are tabulated. The crop made a fair growth in Jackson and Umatilla counties. Late varieties matured with much uncertainty in the latter county.

Growth of the tobacco industry, M. WHITNEY and M. L. FLOYD (*U. S. Dept. Agr. Yearbook* 1899, pp. 429-440, pls. 7).—An historical review of the development of the tobacco industry in Maryland and Virginia and of its extension to other States, with an account of the use of Connecticut tobacco in the cigar industry; requirements of the foreign tobacco trade; manufacturing, smoking, and domestic cigar tobaccos grown and handled in the United States; and statistics of the manufacture of tobaccos, snuff, cigars, and cigarettes in this country, and of leaf tobacco exported from the United States.

Fermentation of tobacco, T. H. VERNHOUT (*Meded.'s Lands Plantentuin*, 1899, No. 34, pp. 49, pls. 2; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 10-11, pp. 377, 378).—Maintains that it is bacterial and that oxydase and peroxydase have no part in the fermentation of Java tobacco.

HORTICULTURE.

Gardening under glass, W. F. MASSEY and A. RHODES (*North Carolina Sta. Bul.* 170, pp. 24).—Under this heading a test of the main varieties of tomatoes for winter forcing is reported, and an essay appended on the use of glass in North Carolina in gardening for the market. Tomato plants were grown in 10-in. pots filled with a mixture of one-half ordinary potting compost and one-half Jadoo fiber and trained to single stems. Pollination was secured by removing pollen with a camel's hair brush and applying the brush bloom by bloom. The dates of gathering and yield of each picking from January to March, inclusive, are shown in tables for each variety. Comments on the character and yield of each variety are appended. Maule Earliest gave the largest yield of any of the varieties tested. It was also the earliest variety grown. The author believes that if this tomato could be bred into a smooth variety it would leave little to be desired as a tomato. In its present irregular shape it is considered unsatisfactory for forcing. Maule Imperial, New Forcing, Stone, and White Excelsior were all promising varieties for forcing. Tapping the plants at noon for the purpose of pollination resulted in an imperfect setting of fruit and rapid falling off in size as compared with the results obtained when hand pollination was practiced.

In the essay on the use of glass for market gardening in North Carolina the subjects of cold frames, sowing lettuce seed for first and second crops, building cheap greenhouses, etc., are discussed.

Forced peas in pots, G. WYTHES (*Garden*, 58 (1900), No. 1505, pp. 231, 232, fig. 1; *Amer. Gard.*, 21 (1900), No. 302, pp. 663, 664).—Forcing peas in pots under glass and varieties suitable for the purpose are discussed. In the author's experience the most satisfactory methods of growing have been to sow from 8 to 12 seed in 9 or 10 in. pots and thin to half the number when the seedlings are strong enough. The soil used should be a firm loam to which bone meal or well-rotted manure has been added, a space being left at the top for later top-dressings. The peas may be planted in the early part of December and the pots placed in cold frames. The sashes should be kept closed until the peas are well above the soil. But little moisture and no heat is required until the plants become well rooted—probably in February. Liquid manure is beneficial as growth proceeds. Sowing in small pots and transplanting to larger increases the labor without benefit to the plants. In case pot plants can not be grown, planting out in frames early in the year, say in January, is advocated. Robust plants which grow from 2 to 3 ft. high are considered most suitable for this purpose. For pot culture very small varieties—6 to 9 in.—are not in favor. Though early they are less prolific than stronger-growing varieties.

One of the best varieties for early pot culture is May Queen. This is a 3-ft. pea, hardy, pods freely, and the peas have a marrow-fat

flavor. Under glass it seldom exceeds 2 ft. in height. Carter Daisy is considered an excellent variety to follow May Queen. This variety grows $2\frac{1}{2}$ ft. high, but may be dwarfed by topping. Gradus, when not forced too hard and grown as cool as possible, is another good variety for forcing, as is also Early Morn. Carter Daisy has proven the most valuable for growing in a warm border in the open.

Apple production in Virginia, W. B. ALWOOD (*Virginia Sta. Bul.* 101, pp. 107-125, map 1).—Statistics obtained in cooperation with the traffic managers of Virginia railroads are given for the shipment of apples from each station along the line of the different roads. Indication is made as to the destination of the shipment, whether to northern or southern tide water, northern or western States, local markets within the State, or to southern States. The matter is also grouped with reference to the apple production of different counties. The shipments of dried apples are noted in some instances. The data are given in detail for 1899. Some data for 1897 and 1898 are also reported. The total production and distribution for the apple crop for 1899 is summarized as follows:

Apple shipments in Virginia in 1899.

	Barrels.
Northern tide water shipments.....	111,589.0
Southern tide water shipments.....	38,452.0
Northern and western distribution.....	14,708.5
Southern distribution.....	37,380.5
Local shipments in the State.....	10,355.0
Total production.....	212,485.0

Analyses of strawberries, G. W. SHAW (*Oregon Sta. Bul.* 62, pp. 6-9).—Physiological, sugar, acid, and ash analyses are reported for a number of varieties of strawberries and the averages of these analyses compared with similar analyses made elsewhere and with analyses of a number of other fruits and vegetables. The analysis with reference to sugar and acid is shown in the table below:

Analyses of strawberries.

Variety.	Average weight.		Flesh.	Waste (hulls).	Sugar.					Nitrogen.	Albuminoids (N. = 6.25.)	Proximate composition.		
	Grams.	Per cent.			Per cent.	Per cent.	Per cent.	Per cent.	Per cent.			Water.	Organic matter.	Ash.
Michael Early	2.39	94.47	5.53	3.07	1.59	4.66	1.08	0.10	0.62	91.52	8.15	0.33		
Vick	10.66	97.27	2.73	3.21	.93	4.14	.95	.18	1.12	81.70	17.91	.39		
Warfield	6.66	96.80	3.20	3.94	1.08	5.02	.89	.11	.69	90.45	9.18	.37		
Glendale	11.30	97.00	3.00	3.27	.88	4.15	1.01	.18	1.12	88.23	11.45	.32		
Sharpless	5.55	97.54	2.46	6.18	.72	.18	1.12	88.22	11.42	.36		
Wilson	4.86	97.59	2.41	5.90	.80	.12	.72	88.14	11.20	.66		
Oregon Everbearing	6.96	96.56	3.44	10.00	.40	.10	.62	87.30	12.12	.58		
Magoon	18.33	97.38	2.62	6.18	.19	88.72	10.79	.49		
Clark Seedling	8.43	95.36	4.64	5.44	.62	6.06	89.02	10.69	.25		
	8.39	96.66	3.34	3.79	5.80	.75	.17	.86	88.57	11.43	.41		

A composite sample of the ash of the strawberries analyzed shows it to contain 39.86 per cent potash, 13.99 per cent of phosphoric acid, and 4.2 per cent of lime.

Investigation and improvement of American grapes at the Munson Experiment Grounds from 1876 to 1900, T. V. MUNSON (*Texas Sta. Bul. 56, pp. 217-286, pls. 20*).—In this bulletin the author surveys in outline the whole field of his more than 20 years' work in the study and improvement of grapes.

The wild or native grapes of the United States are considered in great detail, the natural distribution of the different species being noted and a table presented of their cultural properties, in which are shown the soil preferred by each species; endurance to cold, heat, and drought; resistance to phylloxera, mildew, and black rot; size of the cluster and berry; persistence to pedicel; quality of fruit; season of leafing, flowering, and ripening; and vigor of growth.

In accordance with the cultural facts presented in the table *Vitis vulpina*, *V. rupestris*, and *V. longii*, named in order of preference, are recommended as excellent grape stocks on sandy soils for northern regions of countries like California, France, and other temperate climates where *Vinifera* grapes succeed. For moderately limy soils *V. rupestris* and *V. doaniana* are recommended and for very limy soils, where the ground does not freeze over 18 in. deep, *V. champini*. For grape stocks for any soil in very hot, dry regions, such as southwest Texas and south California, *V. champini*, *V. doaniana*, *V. berlandieri*, *V. candicans*, and *V. monticola* are recommended. "The last 3, being difficult to grow from cuttings, are better utilized in hybrid varieties with the first 2 and with *V. rupestris*. *V. monticola*, *V. berlandieri*, *V. candicans*, and *V. champini*, while doing finely in sandy soil, grow the best of any species in very limy soils, up to 60 per cent of carbonate of lime."

In breeding direct producers of fruit for market and table for the North the best varieties of *V. labrusca*, *V. vulpina*, *V. lincecumii*, *V. bicolor*, *V. rupestris*, and *V. doaniana* are to be selected, using the hardiest and healthiest varieties of *V. vinifera* in attenuation of $\frac{1}{4}$ to $\frac{1}{8}$ or less, by using hybrids and hybrids of hybrids as parents. In the breeding of direct producers for the South, the range is very great. Any of the above may be used with the addition of *V. champini*, *V. bourquiniana*, *V. berlandieri*, *V. monticola*, *V. rotundifolia*, and for Gulf regions and Florida, *V. simpsoni* and *V. munsoniana*.

As to species for wine, "it is found that small-berry species generally possess properties for wine making far superior to the large-berry species, hence if one seeks to produce varieties for wine making he should not neglect those with small berries. The species possessing best wine properties are those in the series *Ripariae*, *Viniferae*, *Æstivales*, *Cinerascentes*, and *Coriaceae*, especially the species *rupestris*, *bourquiniana*, *lincecumii*, *berlandieri*, *champini*, *doaniana*, and *vinifera*."

Reviewing these species selected for special purposes, it is found that American viticulture is based on the following species: *Rupestris*, *longii*, *vulpina*, *monticola*, *berlandieri*, *bourquiniana*, *vinifera*, *lincecumii*, *bicolor*, *vestralis*, *simpsoni*, *candicans*, *doaniana*, *champini*, *labrusca*, *rotundifolia*, and *munsoniana*, 17 in all.

"These with proper application as to climate and soil can well supply all parts, from Puget Sound and Dakota to Puerto Rico. All the other species can be neglected without loss. An abridgement of the above, which would still supply nearly every requirement, and be the best possible list for the number of species included, would be *rupestris*, *vulpina*, *berlandieri*, *bourquiniana*, *vinifera*, *lincecumii*, *simpsoni*, *doaniana*, *champini*, *labrusca*, and *rotundifolia*."

The work involved in hunting the forests for desirable varieties of grapes to be used as parents is noted, and a partial list of varieties of grapes that have been or are growing at the Munson Experiment Grounds given. Following this the author discusses the ideal variety of grape and the personal qualifications necessary in an originator of varieties and gives an account of the methods followed by himself in the creation of new varieties by pure breeding, crossing, and hybridizing.

Crossing and hybridizing when the parent vines bloom at the same and at different times are dwelt on at some length.

"When the intended parent vines do not bloom at the same time, then either the earlier variety must be retarded by cutting off the primary shoots, thus forcing the secondary later, or the later must be made to bloom earlier by pruning close in the fall, soon after the leaf fall, and the earlier delayed as directed above or by not pruning until buds start in the spring or by both, if the natural times of flowering of the 2 intended parents are wide apart, or else by saving pollen of the earlier to apply to the stigma of the later. Pollen can be preserved for weeks and even a year and still be efficient in impregnating."

Directions for collecting and preserving pollen and using the same the following season are given.

The general laws of constitutional development in grapes with reference to the parentage in pollination is stated by the author as follows:

"The most vigorous and enduring progeny are produced by vines as mothers—other things being the same—which have recurved stamens and well-developed pistils, when pollinated by purely staminate vines, as, for example, when Moyer, Lindley, Brighton, etc., are pollinated by staminate seedlings of, say, Dracut, Perkins, Presley, etc.

"Next in vigor are the progeny of mothers having reflexed stamens with large pistils, impregnated by hermaphrodite vines; e. g., Brighton or Lindley by Concord, Ives, Delaware, etc.

"The third in vigor and endurance would be the progeny of hermaphrodite vines, such as Concord, Ives, Perkins, Catawba, and the majority of varieties in cultivation, impregnated by staminate vines. But in this case the majority of the progeny will be staminate vines.

"Fourth in vigor would be the progeny of hermaphrodite vines pollinated by other hermaphrodite vines—for example, Concord pollinated by Delaware or Ives—and still weaker if pollinated by itself or its own progeny, such as Moore Early, Worden, Martha, etc., making 'in-and-in' breeding. The progeny of such impregnations gen-

erally have hermaphrodite or self-pollinating flowers, the kind preferred by vineyardists, who do not understand sex among vines, because they bear planted alone in vineyards. Most hybrids of *Labrusca* with *Vinifera* have been of this class.

"More feeble still, when any progeny at all are produced, is that of vines with recurved stamens, impregnated by varieties with recurved stamens, as in case Moyer could be impregnated by Brighton or Lindley.

"In case a variety with recurved stamens should impregnate itself, if possible, we would expect the feeblest progeny. Such impregnations, however, are very rare, if [occurring] at all. Pistillate varieties thus pollinated generally cast the pistils in a few days afterwards, but the pistils may first enlarge a little. Prof. S. A. Beach has designated such varieties 'self-excitant' or 'self-irritant,' but sterile."

Specific directions for sowing and planting seed, tending and cultivating the seedlings planted in the testing vineyard, noting and selecting the seemingly desirable varieties and breeding with special reference to color of grape, season, size of cluster or berry, or for quality, are given. In the author's experiments only about one really good variety was obtained out of every 1,000 carefully selected and hybridized grape seed grown.

In the course of his work in breeding grapes, Munson has made observations on the prepotency of the different species and the peculiar effect of each on the offspring. Only a few of them need be mentioned here: *V. rupestris* does not seem to be a good mother but in France is considered superior to all other species as a pollenizer of *vinifera* to give direct producers. *V. berlandieri* offers an excellent basis on which to build for large compound clusters and fine quality of berry. *V. lincecumii*, in the opinion of the author, promises more for American grape culture than any other and possibly all other species combined. Among the families of this group, America is uncommonly healthy and vigorous, very prolific, and is a good table and wine grape, and one of the best mothers. A hybrid of *V. bicolor* and *V. vulpina* promises to give rise to a family of very hardy varieties peculiarly adapted to the extreme north. *V. labrusca* is noteworthy for the large number of pure varieties for northern regions to which it has given rise. *V. simpsoni* endures great heat and drought and resists fungus diseases well, especially black rot, and promises well as a base for Gulf State varieties for extremely late ripening. *V. champini* promises much in hybrid combinations. It is a good graft stock for dry, very limy, adobe, or sandy soils, either North or South.

Relative to prepotency or superior potency of one parent over the other the author states as follows:

"Generally the more distinct and uniform a species the more prepotent it is over less distinct and less uniform species. In conformity to this, the more complex a hybrid is, the less it shows of itself in combination with a pure variety of a pure species. Also, in conformity to this law, the more complex a hybrid is, the more variable among themselves are its pure seedlings. We may expect the male parent to more often control in appearance and quality in fruit and the female in vine; yet, if we designate it a general law, there will be found many exceptions."

Report of the horticulturist, R. A. EMERSON (*Nebraska Sta. Rpt. 1899, pp. 50-61*).—Outline of the horticultural work now being carried out at the station and of experiments which have been discontinued.

Experiments conducted for 8 years in the hybridizing and cross pollinating of cucurbits have resulted negatively. In hybridizing different varieties of watermelons with the pollen of pumpkins or squash, no immediate effect of the pollen was discernible on the form, color, or flavor of the fruit or on the size, shape, or color of seed.

New experiments are being undertaken with native ornamentals, cover crops for orchards, orchard cultivation, and in plant breeding.

Progress of commercial growing of plants under glass, B. T. GALLOWAY (*U. S. Dept. Agr. Yearbook 1899, pp. 575-590, pls. 3, figs. 6*).—The historical development and present status of commercial plant growing under glass is considered. It is estimated that about 10,000 commercial establishments in the United States are devoted to growing plants under glass, 1,000 of which are engaged exclusively or nearly so in the forcing of early vegetables which have a retail value of \$4,500,000. The 9,000 commercial florists' establishments are estimated to have on an average 2,500 sq. ft. of glass each, or a total of 22,500,000 ft. The estimated value of these establishments is placed at 50 cts. per square foot of glass and the income to the producer at 50 cts. per square foot annually, or \$11,250,000; and double this amount from the standpoint of the retailer. The retail value of the cut flowers sold is estimated at \$12,500,000, distributed as follows: Roses, \$6,000,000; carnations, \$4,000,000; violets, \$750,000, chrysanthemums, \$500,000; miscellaneous flowers, including lilies, \$1,250,000. The wholesale price of roses, carnations, and violets in the 4 principal cut-flower markets of the country for the years 1890-1899 has averaged \$5.70, \$1.51, and 92 cts. per hundred, respectively. The American Beauty rose is excluded from the above average on account of the high price it commands as compared with other varieties.

The percentage decrease in wholesale prices of roses, carnations, and violets in each of the cities of Chicago, Boston, Philadelphia, and New York during the past 5 years as compared with the preceding 5 years is shown in tabular form.

The Lafleur or English herbaceous graft, E. MARRE (*Prog. Agr. et Vit. (Écl. L'Est), 21 (1900), Nos. 14, pp. 420-427, figs. 8; 15, pp. 443-452, figs. 5*).—The nature, value, and technique of this graft for vines is discussed at considerable length, illustrations being given of the more salient features.

The graft does not change the species, E. BRINGUIER (*Mess. Agr., 5. ser., 1 (1900), No. 6, pp. 208-210*).—A controversial article.

Top grafting and irrigation, J. I. GRAHAM (*Fruit Growers' Assoc. Ontario Rpt. 1899, pp. 20-24*).—A practical paper on the apple, read before the association.

Winter cucumbers in pots (*Gard. Illus., 22 (1900), No. 1125, p. 397*).—A successful method for growing cucumbers in pots is detailed.

The forcing of lettuce (*Amer. Gard., 21 (1900), No. 306, pp. 727, 728*).—Concise cultural directions.

Growing rhubarb in the dark, S. S. BAILEY (*Rural New Yorker, 59 (1900), No. 2644, p. 655*).—The author reports the successful culture of rhubarb in a cellar. The roots were dug in the fall and allowed to freeze, after which they were placed in sand in the cellar and watered. The rhubarb was large enough for use by February 5. Brief suggestions regarding cooking rhubarb are added. Roots 3 or 4 years old are considered most satisfactory for forcing, and where a cellar is not available the roots may be placed in a box and covered with a barrel or other similar arrangement which will keep them in the darkness.

Experiments with tomatoes and potatoes, F. W. RANE (*New Hampshire Sta. Bul. 73, pp. 76-86, figs. 4*).—The importance of the tomato industry is noted and tabulated results given of tests of 15 of the newer varieties of tomatoes grown at the station in 1899 and 48 varieties grown in 1898 and before. The usual data as to the

average yield of ripe fruit per plant, date of first ripe fruit, average weight of green fruit, etc., are recorded and descriptive notes given of 20 varieties of tomatoes not previously mentioned in the station reports. Photographs are given of specimens of each of these varieties.

The report on potatoes shows the results obtained in a test of 47 varieties. The largest average yields for 3 years have been made by Late Puritan, Reeve Rose, Fill-basket, Seneca Beauty, Sir William, White Beauty, Breck Chance, Country Gentleman, Enormous, Harvest Queen, Red American Wonder—all yielding over 315 bu. per acre and mentioned in the decreasing order of their productiveness.

The tomato and its culture, M. LERCA (*Queensland Agr. Jour.*, 7 (1900), No. 3, pp. 229-232, fig. 1).—Raising early plants, soil preparation, yields, and varieties are popularly considered.

Stripping bark from apple trees, N. O. BOOTH (*Rural New Yorker*, 59 (1900), No. 2642, pp. 621, 622, figs. 6).—Some inconclusive experiments are recorded in removing strips of bark 2 to 3 in. wide from the trunks of a Rambo and a Ben Davis apple tree. The effect of the gnawing of the bark by sheep is also noted. Stripping is a devitalizing process and is employed to throw trees into bearing. When the cambium is not harmed the wound soon heals over. Abrasions of the cambium result in more serious injury to the tree when they take a transverse rather than a longitudinal trend.

Some data are given on the effect of removing strips of bark from apple trees every 10 days from March 20 to July 20.

New plums, L. BURBANK (*Rural New Yorker*, 59 (1900), No. 2644, p. 655, figs. 4).—Some new plums originated by the author are described.

Plantains and bananas, P. G. WICKEN (*Jour. Dept. Agr. West. Australia*, 1900, Aug., pp. 59-62).—Notes on methods of culture and uses of these fruits.

Lemon culture in Italy, H. DIXON (*Agr. Gaz. New South Wales*, 11 (1900), No. 9, pp. 719, 720, figs. 2).—Methods of protecting the trees from the sun and frost by means of upright posts connected with horizontals and covered over with grass, straw, etc., are noted.

Lemon pruning (*Pacific Rural Press*, 60 (1900), No. 14, p. 209, figs. 5).—The Baronio method of pruning lemons is illustrated and described. It consists in cutting out the whole center of the tree, followed by cutting out the upright growing shoots or suckers and encouraging the growth of small shoots or fruiting spurs on a flat framework.

Orange-tree roots, J. H. REED (*California Cultivator*, 14 (1900), No. 21, pp. 321-323).—The penetration of orange-tree roots in irrigated orchards is noted.

The persimmon in Iowa, F. O. HARRINGTON (*Trans. Iowa Hort. Soc.* 1899, pp. 251-256).—The possibilities of persimmon culture in Iowa are pointed out, and detailed directions given for all the different operations connected therewith.

Growing strawberries in New England, F. W. RANE (*New Hampshire Sta. Bul.* 74, pp. 88-106, figs. 6).—Cultural notes, reprinted from a previous bulletin of the station (E. S. R., 10, p. 48), and the results of tests of varieties are given. Tabulated comparative data as to blooming period, first ripe fruit, yield, drought resistance, etc., are tabulated for 86 varieties tested in 1899. Descriptive notes are given on 10 of the more popular varieties and on 29 of the later introductions. The following varieties are considered of most merit: Beverly, Brandywine, Bubach, Clyde, Crescent, Greenville, Haverland, Lovett, and Warfield.

Eureka and Kansas raspberries, C. C. NASH (*Amer. Gard.*, 21 (1900), No. 302, p. 662).—From the results obtained in comparative tests with the black raspberries in 1899, the author gives his preference to the Kansas variety. It produces plenty of strong, vigorous fruiting canes on either sandy or clay soil, and is more hardy than Eureka.

The alligator pear, D. BOIS (*Rev. Hort.*, 72 (1900), No. 19, pp. 546, 547, pl. 1).—This tropical fruit (*Persea gratissima*) is illustrated and notes given on its culture and uses.

India rubber, J. PARKIN (*Indian Forester*, 26 (1900), No. 7, pp. 341-349).—Notes on the origin, collection, and preparation of India rubber.

Caoutchouc in German East Africa (*Tropenpflanzer*, 4 (1900), No. 8, pp. 367-378).—The report of the governor of German East Africa to the home office. Notes on culture experiments are recorded and some commercial data given.

Repeated tapping of *Ficus elastica*, A. PREYER (*Tropenpflanzer*, 4 (1900), No. 8, pp. 404-406).—Trees were tapped in one experiment at intervals of 7 to 10 days and the coagulated caoutchouc removed. The incisions were made close under each other. About $7\frac{1}{2}$ times as great a product was thus obtained with 5 tapplings as is usually obtained where only 1 tapping is practiced. In another instance the intervals between tapplings were reduced to 3 and 2 days, respectively, and 3 tapplings made. Again the product secured was nearly 3 times that secured with only 1 tapping. The repeated tapping is said not to hurt the trees as in some parts of the province of Subany, the practice of repeated tapping of the same trees has been carried on by the natives for years without harm.

Pecan groves, H. ROST (*Proc. Texas Farmers' Cong.* 1900, pp. 130-138).—Varieties to plant and the profits in growing pecans are considered.

Flower odors (*Wiener. Illus. Gart. Ztg.*, 8 (1900), No. 9, pp. 260-263).—The classification of flower odors is considered. Deppino's classification of flower odors into sympathetic and idiopathic kinds is used as the basis of the author's remarks, many examples of the odors of flowers coming under the two headings being given.

Fall-sown asters (*Amer. Gard.*, 21 (1900), No. 302, p. 660).—In experiments on the *American Gardening* trial grounds fall-sown aster seed withstood the rigor of winter and came up abundantly in the spring. The plantlets were transplanted into rows alongside of plants grown from spring-sown seed. The plants from spring-sown seed promised better in the early part of the season, but as they began to come into bloom they were attacked and destroyed by disease. The plants from the fall-sown seed seemed more robust, grew well, and blossomed, and up to the time of writing not a plant had been lost by disease. The results are considered suggestive for further experimentation.

Different methods of orchid culture (*Florists' Exchange*, 12 (1900), Nos. 33, p. 789; 34, p. 824; 35, p. 848).—Besides certain general principles and a discussion of the usual methods employed in the culture of orchids, the late methods of certain Belgian and French florists are discussed. The new feature consists in potting orchids in leaf mold, a little sphagnum being placed in the bottom of the pots to prevent the mold from washing through. Excellent results are reported by this method of culture, and the author recommends the method for trial in this country.

Orchids from seed, E. O. ORPET (*Amer. Gard.*, 21 (1900), Nos. 300, p. 634; 303, p. 680; 306, pp. 728, 729, fig. 1).—Some of the precautions to be observed in growing orchids from seed are pointed out.

Sweet-pea culture, H. H. GIBSON (*Farmers' Gaz.*, 59 (1900), No. 38, p. 743).—The use of various manures in heightening the color of sweet peas is discussed and cultural directions given.

Sweet violets and their culture, R. PARKER (*Garden*, 58 (1900), No. 1506, pp. 246-248).—Outdoor culture, winter forcing, and varieties for the open are discussed.

Hedges, wind-breaks, shelters, and live fences, E. P. POWELL (*New York: Orange Judd Co.*, pp. 140).—A treatise on the planting, growth, and management of hedge plants for country and suburban homes.

School gardens, F. M. POWELL (*Trans. Iowa Hort. Soc.* 1899, pp. 141-149).—A somewhat extended review of the purpose and development of school gardens in this and European countries.

School gardens, E. GANY (*Rpt. U. S. Com. Education, 1898-99, I, pp. 1067-1084; transl. from Rein's Pedagogical Cyclopedia*).—Discusses the history of school gardens and gives detailed directions for their management and use.

Report of the committee on school gardens and children's herbariums for the year 1899, H. L. CLAPP (*Trans. Mass. Hort. Soc. 1899, pt. 2, pp. 255-280, pls. 7*).—A number of school gardens in Massachusetts are briefly described. Notes are given on the character of each and on the use of the gardens by the children. German school gardens are commented upon. Suggestions regarding prizes for school gardens, with a list of prizes and gratuities awarded for school gardens and herbariums in 1899, are added.

Gardening by the Columbia, Missouri, public schools, J. C. WHITTEN (*Amer. Gard., 21 (1900), No. 292, pp. 504-506*).—Notes on methods of nature study and window gardening at the school and on results obtained.

FORESTRY.

Forest reserves in the United States, H. GANNETT (*Nineteenth Ann. Rpt. U. S. Geol. Survey, 1897-98, pt. 5, pp. 400, pls. 110, figs. 2; obs. in Forester, 6 (1900), No. 3, pp. 55, 56*).—A preliminary statement is given of the forest areas of the United States, particular attention being given to their geographic and economic consideration. It is said that of the United States, exclusive of Alaska, 37 per cent of the entire area is wooded.

A summary is given of the available information of the estimated merchantable timber of various species occurring in the different States. Reports are given on several of the timber reserves as follows: Black Hills Forest Reserve, H. S. Graves; Bighorn Forest Reserve, F. E. Town; Teton and Yellowstone Forest Reserves, T. S. Brandegee; Priest River, Bitterroot, San Jacinto, San Bernardino, and San Gabriel Forest Reserves, J. B. Leiberg; Washington Forest Reserve, H. B. Ayres; Eastern Part of Washington Forest Reserve, M. W. Gorman; Forest Conditions of Northern Idaho, J. B. Leiberg; and Pine Ridge Timber, Nebraska, N. H. Darton.

Practical tree planting in operation, J. W. TOUMEY (*U. S. Dept. Agr., Division of Forestry Bul. 27, pp. 27, pls. 4, figs. 2*).—This bulletin describes some of the practical workings of the cooperation with tree planters begun by the Division in 1899 under the provisions of Circular 22 (E. S. R., 11, p. 745). In addition it describes the result of successful plantings in the past both for general and for special purposes. The form of tree-planting agreement which is entered into in all cooperative investigations is given and the plan explained at some length. Under this cooperative system applications for assistance were received from nearly every State in the Union, more than 90 per cent, however, coming from the treeless regions of Texas, Oklahoma, Kansas, Nebraska, and the Dakotas.

Some of the difficulties attending tree planting are mentioned. The chief object of the cooperative work of the Division is to assist tree

planters in overcoming these adverse conditions, and to aid in the establishment of plantations to the greatest possible value of their owners. A number of plantations are described, and working plans for others given. Suggestions are given for the care of nursery stock and methods to be followed for the successful transplanting of evergreens.

A catalpa plantation, located in the sandy valley of the Arkansas River in Kansas, is described at some length. This plantation consists of 440 acres planted with hardy catalpa, the first planting having been done in 1890 and the last in 1892. A measured portion of this plantation was estimated to contain timber of a gross value of \$267.15 per acre as the result of a 10-year crop. If from this gross amount the expenses incurred as well as the interest on the gross investment be deducted, there will be found a net profit of \$197.55 per acre. This profit can be considerably increased if only a portion of the trees be marketed each year for the next 10 years.

Pure woods or mixed woods, W. SCHLICH (*Gard. Chron.*, 3. ser., 27 (1900), No. 696, pp. 257, 258).—The author gives the results of his investigations on the subject of pure and mixed forests. The species of trees suitable to be grown in pure woods are beech, hornbeam, silver fir, spruce, sycamore (*Acer pseudoplatanus*), white pine, and Douglas fir. Those doing best in mixed forests are larch, birch, poplar, ash, oak, and chestnut. The author states that only species which are capable of preserving the yield capacity of the locality should be used in pure woods. In the case of mixed woods one of the species of the mixture must be a soil-improving one, and it should be more numerous than the others. As a rule not more than 2 or 3 species should be mixed on the same area unless placed in separate groups, representing a series of small pure woods. Shade-bearing species may be mixed with each other, provided their rate of growth in height is the same; but the slower growing must be protected against the other tree by giving it the start or cutting away the threatening individuals of the faster-growing species. Shade-bearing and light-demanding species may be mixed if the latter are the faster growing or have been given the start. Light-demanding species should not be mixed with each other except in very fertile localities, in inferior localities where nothing else will grow, in temporary mixtures where one is used to protect another, or if the wood is treated under very short rotation. Whether the mixture should be arranged by single trees or whether each species should form separate groups depends upon various circumstances, the principal of which is the relative height growth and shapes of the different trees.

Observations on the temperature, growth, and moisture content of various trees, W. R. LAZENBY (*Proc. Soc. Prom. Agr. Sci.*, 1899, pp. 35-42).—A report is given on observations made to determine

the variations in temperature of trees in which the temperature of oak and pine trees of different diameters were compared with the temperature of the open field. The author reports a variation of about 4° F. between the temperature of the open field at a distance of 10 rods from the temperature readings of a narrow strip of woodland where these experiments were conducted. The readings of the different thermometers for the month of February are given and comparisons made with temperatures taken from apple trees in another series of investigations. The records show that the temperature of trees of the smaller diameter follow more nearly that of the atmosphere than in the case of the larger trees. The temperature of the trees did not respond to slight variations in the external temperatures and never reached the same maxima and minima as shown by the thermometers in the open air. Decided variations in the temperature of the open air were followed by similar variations in the internal temperature of the trees in from 24 to 72 hours, depending largely upon the diameter of the trees.

The second part of the paper reports a summary of results of observations to determine the amount of growth made by a series of trees during the growing season of 1898. The moisture content of the same trees was determined at the same time. The trees investigated were the American elm, black walnut, Carolina poplar, magnolia, red oak, sugar maple, and white ash. All these trees were 10 years old, with the exception of the Carolina poplar, which was 6 years old. In height the trees varied from 15 to 25 ft., and in diameter from 3 to 5 in. Measurements were made of the upright, terminal, and lateral branches, and are recorded in tabular form. The percentage of moisture in the same trees was determined, in which it is shown, as would naturally be expected, that the softer woods contained the highest percentage of moisture.

The production of high-class oak, ash, and larch timber, W. SCHLICH (*Gard. Chron.*, 3. ser., 27 (1900), No. 697, pp. 274, 275).—Suggestions are given for the proper management of these species for the production of timber in England. All are light demanding, are thin crowned, and none of them improve the yield capacity of the locality if raised in pure woods. The best way of rearing them is said to be to mix them with the shade-producing, full-crowned species. The species best adapted for this purpose is said to be beech.

Oak and beech mixtures and ash and beech mixtures are described at some length. The growing of larch and beech is of particular importance since the larch disease has spread throughout Great Britain. Oak, ash, and larch woods may be under planted with silver firs instead of beech. Scotch pine has been used with favorable results in the same way.

Progress of forestry in the United States, G. PINCHOT (*U. S. Dept. Agr. Yearbook 1899*, pp. 293-306, pls. 4, map 1).—The early attitude of the inhabitants of this country toward forestry is indicated. The development of the forestry policy of the Government is traced, and the administration of the national forest work and national parks described. Notes are given on private and State forestry, and forest-fire legislation. The establishment and work of the Division of Forestry of this Department are described and some of the lines of investigation mentioned. Attention is briefly called to forest associations and institutions of the United States offering instruction in forestry. Arbor day as a factor in influencing respect for trees and preparing a sentiment for practical forestry is mentioned.

Progress in tree planting in the United States, J. W. TOUMNEY (*Forester*, 6 (1900), No. 9, pp. 213, 214).—In a paper read before the American Forestry Association in New York, June 25, the author briefly reviewed the work of the Division of Forestry of this Department, explaining the plans for cooperation, by which practical assistance is given to farmers and other landowners in establishing plantations of forest trees for economic purposes.

North American forests and forestry, E. BRUNCKEN (*New York: G. P. Putnam's Sons*, 1900, pp. 265).

The practice of forestry by private owners, H. S. GRAVES (*U. S. Dept. Agr. Yearbook 1899*, pp. 415-428, pls. 4).—The general movement in the United States in favor of conservative forestry is said to have begun about 25 or 30 years ago. The early efforts of private owners to preserve forests are described, the systems having been devised by the owners themselves. In many cases these systems could be materially improved, but the results show that more has been done in the way of forestry in this country than is generally supposed. Forest management under systematic working plans is described, and methods for forest planting and controlling forest fires are given.

Technical exploitation of forests, H. VANUTBERGHE (*Exploitation technique des forêts. Paris: Gauthier-Villars*, 1900, pp. 176).

Statistical report on the growth and development of various conifers in Schovenhorst, etc., J. H. SCHÖBER (*Berlin: Julius Springer*, 1900, pp. 34).

Ancient pollard oaks (*Garden*, 57 (1900), No. 1479, p. 217, figs. 3).—Notes are given on 3 pollard oaks which are thought to be 1,800 years old. The trees measure 20 ft. 9 in. and 28 ft. 4 in. in circumference at the smallest portion of their trunks.

Reproduction of timber in the black-jack forests of Oklahoma, W. L. HALL (*Forester*, 6 (1900), No. 7, p. 164).—Notes the rapid reforestation of former areas covered with this oak. Associated with it are often found other oaks, hackberry, white elm, etc. Hardy catalpa, black locust, and black walnut have been successfully introduced among the natural forest growth.

Extermination of the red cedar in Oklahoma, W. L. HALL (*Forester*, 6 (1900), No. 7, p. 163).—Notes the almost total extermination of a former abundant red cedar crop by cutting for posts and removal of young trees for ornamental purposes. It is said that at least 99 per cent of the latter died as a result of the transplanting.

Some timber trees of Queensland, J. W. FAWCETT (*Queensland Agr. Jour.*, 6 (1900), No. 4, pp. 313-315).—Descriptive notes are given on *Angophora subvelutina*, *A. intermedia*, and *A. lanceolata*.

Notes on the timber trees of the Burnett district of Queensland, J. W. FAWCETT (*Queensland Agr. Jour.*, 6 (1900), Nos. 5, pp. 396-399; 6, pp. 505-508).—Brief notes are given on 63 species of timber trees and the characteristics and uses of the timber are pointed out.

Fires in the forests of *Pinus maritima*, E. MUEL (*Jour. Agr. Prat.*, 1900, I, No. 17, pp. 598-600).—A tabular summary is given of the destruction done by forest fires in the maritime provinces of France. In 1899 over 13,900 hectares were burned over, at an estimated loss of 1,665,470 francs.

The composition of cork oak and its bearing on forestry, E. GINSTINIANI (*Jour. Agr. Prat.*, 1900, I, No. 21, pp. 743-745).—Analyses are given of the bark and wood, and of the ash of bark, wood, roots, leaves, and acorns of the cork oak, and the bearing these analyses have upon forests and forest planting.

The Robinia and its exploitation, P. MOUILLEFERT (*Jour. Agr. Prat.*, 1900, I, Nos. 16, pp. 578-581; 17, pp. 603-605, fig. 1).—Notes are given on the value of *Robinia pseudacacia* for forest planting.

On the working qualities of some colonial timbers, H. STONE (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 4, pp. 217-225).—A report is given of the results of a series of technical tests of a number of species of indigenous and introduced timbers.

Growing Norway spruce for paper pulp, T. L. DUNCAN (*Amer. Gard.*, 21 (1900), No. 296, pp. 567, 568).—The author recommends the growing of Norway spruce (*Picea excelsa*) for paper pulp manufacturing. Data are given on the rate of growth of a number of lots of this spruce in Minnesota, and under proper conditions of culture and fire protection it is believed that it would furnish a crop suitable for wood pulp in from 25 to 30 years, a period much less than the time required for the growth of the ordinary white and red spruce.

A suggestion for the estimation of cord wood, G. F. SCHWARZ (*Forester*, 6 (1900), No. 4, pp. 76-78).—The author explains a system of estimating cord wood in standing forests, which method is known in Europe as the "absolute factor of shape." It is considered a very accurate one and has been employed extensively in Denmark with entire satisfaction. In a beech and oak forest in Germany this method was tested and proved more accurate than measurements made by other systems. The method is believed to possess certain advantages over the others and to be adaptable to the varying conditions of American forests.

Practical estimation of timber, P. MOUILLEFERT (*Jour. Agr. Prat.*, 1900, I, No. 12, pp. 427-430).—Formulas are given for the estimation of wood and timber in forests.

Railroad forestry, J. H. SUTOR (*Sci. Amer. Sup.*, 50 (1900), No. 1286, pp. 20619, 20620).

Means for preventing worm holes in timber, E. MER (*Jour. Soc. Agr. Brabant-Hainaut*, 1899, pp. 434, 435).

Fireproofing wood (*Sci. Amer.*, 83 (1900), No. 4, pp. 49-55, figs. 4).—A description is given of a method of fireproofing wood for building purposes.

SEEDS—WEEDS.

Twenty-first annual report of the Swiss seed control station at Zurich, F. G. STEBLER, E. THIELÉ, and A. VOLKART (*Lundw. Jahrb. Schweiz*, 14 (1900), No. 1, pp. 48, figs. 2).—A report is given of the activities of the station during the year ended June, 1899. During this period 8,473 samples of seed were tested, the investigations requiring 21,274 tests. These trials served as the basis of a guarantee for about 350,000 kg. of clover and grass seed. Most of the samples of seed tested for consumers were found in excess of the guarantee, few, if any, falling below the difference allowed by the regulations of the station.

A tabular statement is given showing the result of the year's tests of different seeds, and also the average percentage of purity, germination, and intrinsic worth of all seed examined since the establishment of the station. Detailed statements are also given of the tests of clover and grass seeds and grass seed mixtures.

Experiments are briefly reported in which is shown the comparative value of crops grown from seeds of different origin. Timothy from American seed gave a slightly larger yield than that from German seed. Alfalfa from American seed yielded least of 4 kinds. Alfalfa from different parts of Russia varied widely in the quantity of green fodder produced. The relative yields of orchard grass from forest-grown and field-grown seed were tested, to the decided advantage of the field-grown seed. Comparisons were made between the yields of American, New Zealand, French, and Swiss grown orchard grass, in which the yields secured for 3 years are shown. Except for the New Zealand seed, which was considerably lower than the others, there was but little difference in the different lots.

Notes are given on the weed seeds found in alfalfa seed from different countries, especial attention being paid to *Cuscuta racemosa*, a South American dodder which is said to occur in seed from that country.

The time required for the germination of seed of *Pinus sylvestris* was investigated. Different lots of pine seed which showed varying degrees of vitality were tested, the sprouted seeds being counted on the sixth, ninth, twelfth, fifteenth, twenty-first, and thirtieth days. It was found that of the germinable seed of the different lots, all but about 10 per cent sprouted within 15 days.

Effect of formaldehyde on the germination of cereals and on smut spores, S. DAVID (*Sitzber. Naturf. Gesell. Univ. Dorpat*, 12 (1899), No. 2, pp. 202-204, 222-247).—Investigations are reported showing the effect of formaldehyde upon the germination of wheat, maize, oats, and barley and upon the spores of smuts of these cereals. Different lots of seed were subjected to varying strengths of formaldehyde solutions for 1, 3, 6, 12, 18, and 24 hours, after which their germination was tested. The strengths of solutions used were 0.025, 0.05, 0.125, and 0.25 per cent of formaldehyde, and comparisons were made with equal quantities of seed soaked in distilled water for equal lengths of time. The effect of formaldehyde vapors was tested in a similar manner.

The results of the experiments are shown in tabular form, from which the effects of the treatments of seed upon their germination may be seen. An injurious effect is noted upon different cereals, being most marked in the experiments with oats. The extent of injury is in proportion to the strength of solution and time of soaking. The injury is manifested in retarded germination, in abnormal germination in which no roots were produced although the seeds sprouted, and in dead seed. The action of the solutions on the spores of smuts was quite marked, a few hours' treatment destroying the spores of *Ustilago avenae*, *U. hordei*, *U. maydis*, and *U. destruens* adhering to the treated seed. After treating the seed the injurious effects of formaldehyde may be diminished by soaking the seed in a weak solution of ammonia for 15 minutes.

Seed selling, seed growing, and seed testing, A. J. PIETERS (*U. S. Dept. Agr. Yearbook 1899*, pp. 549-574, pls. 5, fig. 1).—The beginning and development of the seed industry in the United States, the methods of seed growing of different kinds, the regions and conditions favorable for profitable seed growing, and seed testing are described. The methods of seed testing pursued by different commercial seedsmen and those followed by this Department are outlined.

Technical regulations of the Association of German Agricultural Experiment Stations for seed testing (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, pp. 91-100).—The rules relative to samples, sampling, and testing are given.

The after-ripening of oats, W. KINZEL (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, p. 133).—A report is given of tests of the germination of oats at bimonthly periods after harvesting. The percentage of germinable seed was found to steadily increase for 8 to 10 months, after which there was a decrease.

Canada thistle, L. H. DEWEY (*U. S. Dept. Agr., Division of Botany Circ.* 27, pp. 14, figs. 4).—Illustrative and descriptive notes are given on the Canada thistle, in which its history, introduction, present range, and methods of distribution are discussed in greater or less detail. Numerous methods of eradication are suggested, the success of any of them depending upon the thoroughness with which it is carried out.

DISEASES OF PLANTS.

The diseases of beet seeds and means for combating them, LINHART (*Oesterr. Ungar. Ztschr. Zuckerind.*, 1899; *abs. in Ztschr. Pflanzenkrank.*, 10 (1900), No. 2, pp. 116, 117).—A number of fungus and bacterial diseases of beets that seem to be communicated through the seeds are described. The bacterial disease is attributed to *Bacillus mycoides*. Associated with it were found *Bacillus subtilis*, *B. fluorescens liquefaciens*, and *B. mesentericus vulgatus*. *B. mycoides* is considered the cause of the disease commonly known as bacteriosis and also that on young plants known as black shank. The fungus diseases found were those caused by *Phoma betæ* and *Pythium debaryanum*.

As a means for preventing these diseases it is recommended that the "seed" be soaked for 30 minutes in concentrated sulphuric acid, after which they are washed for 10 minutes in a strong stream of running water and then soaked 2 hours in milk of lime and washed 4 hours in water. This treatment does not injure the seed, while it destroys all spores adhering to the hard seed coat.

Bacteriosis of beet roots, A. STIFT (*Oesterr. Ungar. Ztschr. Zuckerind.*, 1899, p. 605; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 3, p. 373).—A description of diseased beets and results of inoculation experiments with cultures of *Bacillus betæ* are given. The bacillus was cultivated on agar. It is about $4\ \mu$ long by 0.9 to $1\ \mu$ broad. Its ends are rounded and in hanging drops actively motile. Flagella are numerous and very delicate. In cane-sugar-meta-peptone gelatine sugar was completely decomposed without the evolution of gas, a fact, it is said, which suggests that the conversion of sugar was due to hydrolysis. The organism liquefies gelatine and on agar slants presents a slight irregular growth.

An inquiry into the cause and nature of crown gall, J. W. TOUMEY (*Arizona Sta. Bul.* 33, pp. 64, figs. 31).—This bulletin is a continua-

tion of investigations reported upon in the Annual Report of the station for 1899 (E. S. R., 11, p. 858). The previous publications relating to this disease are briefly reviewed and the geographical distribution in the United States outlined. The various field experiments that have been conducted by the author are reviewed at considerable length, together with his inoculation experiments. The investigations of the author seem to indicate the parasitic nature of the disease and its ready transmission in the soil or by means of inoculation experiments.

The crown gall, in the author's observations, has been noted upon the peach, apricot, almond, prune, plum, apple, pear, English walnut, and grape, and it is reported by others to occur on the raspberry, blackberry, cherry, poplar, and chestnut.

The crown gall, according to the author, is annual in its period of growth, beginning in the spring and maturing in the fall. However, in Arizona galls sometimes develop late in the summer and continue their growth throughout the winter when the normal tissues of the tree are dormant. At first appearance the galls appear as a clear, white, translucent mass of soft, succulent tissue, a millimeter or less in diameter and nearly or quite spherical. It is most frequently attached to the host by a narrow neck $\frac{1}{2}$ to $\frac{1}{4}$ of the body of the gall. When grown above ground or in water cultures, so as to have access to light, the galls change to a light green from the development of chlorophyll in their outer cells. At first the gall has a rather uniform outer surface, which becomes warty after a time from unequal growth. The white appearance of the gall is lost early in its life and the outgrowth becomes a reddish brown. Any portion of the gall which has changed color has lost the power of further growth. When the galls decay, as is usually the case at the end of the season's growth, it leaves an open wound through the bark which extends some distance into the wood. The following spring a more or less interrupted circle of gall tissue forms around the wound caused by the gall of the previous year. The galls become larger and deeper each succeeding year until finally the stem becomes so weakened that the tree breaks off.

The cause of the crown gall, in the author's estimation, is due to a specific organism belonging to the slime molds to which the name *Den-drophagus globosus* is given. The various stages of the parasite are described at considerable length and a number of successful inoculation experiments, in which sclerotia were used, are described. The effect of the parasite on its host is noted and the various phases through which the organism passes are described.

The organism which is considered new, both generically and specifically, is described as follows:

"Plasmodium parasitic; peridial wall brittle, nonpersistent, shining, breaking in straight lines into small irregular pieces; capillitium fragmentary, formed of a few irregular, branching tubules attached to the lower portion of the peridial wall.

"Sporangia sessile, occurring singly or in groups of 2 or 3, 1 mm. or less in diameter, globular or slightly flattened and resting directly upon the tissue of the host, deep orange, shining, opening irregularly; peridium thin, minutely granular when highly magnified, the interior surface more or less covered with yellow protoplasmic nodules of variable size and refractive power; capillitium of a few thick, blunt, sparingly branched, and irregular nodular hollow threads; spores orange yellow, adhering in masses, smooth, $1\frac{1}{2}$ to $3\ \mu$ in diameter."

Its affinities with Plasmodiophora, which causes club root, are indicated, comparisons being drawn between this organism and some recent studies by Nawaschin on Plasmodiophora.

But little is known concerning the remedies for this disease aside from negative results. The author's and others' investigations have shown that sulphur is of no avail as a remedy. From the position and character of the disease it seems evident no remedy will completely overcome it after an orchard is once attacked. The safest advice is to see that young trees when planted in orchards are not infested and have not come from known infested nurseries. Where the disease has established itself in an orchard, the life of the trees may be prolonged for a time by cutting off the galls from the crowns of the roots and covering the injury with a mixture of copper sulphate and lime in the form of a thick paste.

Stigmonose: A disease of carnations and other pinks, A. F. Woods (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 19, pp. 30, pls. 3, figs. 5*).—Previous publications by the author on this same subject have been noted (*E. S. R.*, 9, pp. 657, 852). In the present bulletin the investigations of Arthur and Bolley on this disease have been thoroughly reviewed and no evidence found that this disease is of bacterial origin. A full account is given of the investigations conducted by the author, in which he found that the primary cause of the disease was due to punctures made by aphides and thrips, while another form of the disease is commonly caused by injuries produced by red spiders. The effect of the disease on the plant as a whole depends upon its vigor and the number of punctures, and the susceptibility of different varieties to injury seems to be, as a rule, proportionate to the normal vigor of the variety. Methods are suggested for controlling the disease which can be successfully done by the proper selection of cuttings, careful propagation of stock, good soil, proper amount of moisture, light, and air, and by the reduction of aphides, thrips, and red spiders to a minimum.

Progress in the treatment of plant diseases in the United States, B. T. Galloway (*U. S. Dept. Agr. Yearbook 1899, pp. 190-200, figs. 2*).—A review is given of the work for the past century on the treatment of plant diseases, from which it appears that the greatest progress has been made within the past 15 years. The beginnings of modern research are placed at about 1870, since which time great activity has taken place both in the United States and abroad. The period between 1888 and 1895 is characterized as an epoch-making one on account of the rapid strides made in discovering the causes of plant diseases and methods for their prevention.

Some results of the work which have been obtained in this country are briefly outlined, examples being cited in grape diseases, nursery stock diseases, diseases of cereals, etc.

The diseases of cultivated plants, V. PEGLION (*Le malattie crittogamiche della piante coltivate. Casali: Carlo Cassone, 1899, pp. VII+311*).

Plant diseases investigated at St. Petersburg in 1898, K. S. IWANOFF (*Ztschr. Pflanzenkrank., 10 (1900), No. 2, pp. 97-102*).—A brief report is given on 160 species of fungi which were observed on 230 species of host plants. They are classified by hosts as follows: Cereals and grasses, clovers and legumes, potatoes, garden plants, fruit trees, berries, ornamentals, forest trees, and weeds. Among the number of fungi were several new species.

Parasitic algæ and fungi of Java, III, M. RACIBORSKI (*Batavia: Staatsdruckerei, 1900, pp. 49*).

A monograph of the Erysiphaceæ, E. S. SALMON (*Mem. Torrey Bot. Club, 9 (1900), pp. 1-292, pls. 9*).—A monograph of the species of powdery mildews is given, together with notes upon their morphology and life history, relation of host and parasite, and the distribution of the powdery mildews. The author limits the family to the genera *Podosphæra*, *Sphærotheca*, *Uncinula*, *Microsphæra*, *Erysiphe*, and *Phylactinia*. Of these, 49 species and 11 varieties are recognized. Under the discussion of the various species notes of their economic importance are given. The species of *Oidium* are considered as conidial forms and for the most part are not described.

Concerning the geographical distribution of rust fungi, P. DIETEL (*Naturw. Wehnschr., 15 (1900), No. 19, pp. 217-220*).

The depreciation of the yield of wheat due to rust, A. GRÉGOIRE (*Bul. Sta. Agron. Gembloux, 1900, No. 67, pp. 14, 15*).—An account is given of pot experiments conducted to determine the loss due to rusts of cereals. Six series were grown, in which the loss of straw was from 8 to 23 per cent, with an average of 17 per cent, and in grain the depreciation was from 21 to 40 per cent, with an average of 35 per cent. The number of grains per head and average weight of the individual grain was considerably lower for the plants affected with rust.

Recent investigations on rust of wheat, W. G. SMITH (*Nature, 62 (1900), No. 1606, pp. 352-356, figs. 2*).—A review is given of the recent publications of Eriksson, Klebahn, Carleton, and others on rusts of cereals.

Investigations of the rust fungi of cereals in Austro-Hungary, H. ZUKAL (*Ztschr. Pflanzenkrank., 10 (1900), No. 1, pp. 16-21*).—A report is given of studies on the cereal rusts of Austro-Hungary. The species observed were *Puccinia graminis* on rye, *P. glumarum* on wheat, *P. simplex* and *P. graminis* on barley, and *P. graminis* and *P. coronata* on oats. The author tentatively adopts the name *P. glumarum* for the rust on wheat. Culture experiments were made of the different species, and negative results were obtained in experiments for preventing the attacks of rusts. In relation to Eriksson's mycoplasma theory the author is led to believe some infection may possibly be secured through mycelium carried in the seed grain. Investigations on alternate generations showed that the rust fungi are not confined to certain definite transition hosts for their phases.

Experiments with smuts of cereals, C. N. GRENFELL (*Agr. Gaz. New South Wales, 11 (1900), No. 9, pp. 742-747*).—Inoculation experiments are reported with *Tilletia tritici*, *Urocystis occulta*, and *Ustilago segetum*. Soaking seed in copper sulphate as a means of preventing smuts was successfully investigated, the treatment tending to reduce the amount of disease. It is claimed that *Ustilago segetum* decreases and *Urocystis occulta* increases the tillering tendency of wheat plants. The infection of the loose smut, *U. segetum*, is said to take place at an earlier stage of the plant than the others, probably occurring in the seed.

Infection experiments with some Uredineæ, E. FISCHER (*Bot. Centbl., 83 (1900), No. 3, pp. 75, 76*).—Successful inoculations of *Actæa spicata* with teleutospores of a

Puccinia from *Triticum caninum* are reported, from which it is claimed the *Æcidium actææ* is to be associated with a Puccinia of the type of *P. persistans* on *Triticum caninum*. Basidiospores of *Puccinia buri* sown upon young box leaves gave positive results. The infection was one month in becoming manifest, and the teleutospores were formed the following year.

Blight of maize, J. MARWICK (*Agr. Jour. Natal*, 3 (1900), No. 11, pp. 321-323).—A popular account is given of a disease of maize due to some apparently unknown cause. The affected plants are stunted in growth, have striped leaves, and are generally worthless.

The diseases of the sugar beet, A. STIFT (*Die Krankheiten der Zuckerrübe*. Vienna: W. Frick, 1900, pp. VIII+115, pls. 15).

A contribution to the bacterial disease of sugar beets, A. STIFT (*Ztschr. Pflanzenkrankh.*, 10 (1900), No. 1, pp. 5-15, figs. 2).—An account is given of a bacterial disease of sugar beets, a description of the organism isolated, and its effect as shown by inoculation experiments and analyses of diseased roots.

The heart rot of beets, J. PARFONDY (*Jour. Soc. Roy. Agr. L'Est., Belg.*, 1900, p. 226).

A new disease of radishes, G. R. B. VON MANNAGETTA (*Sitzber. Deut. Naturw. Med. Ver. Böhmen-Lotos*, 1899, No. 8, pp. 3).

Diseases of the potato and their treatment, H. POTEL (*Bol. Inst. Agron. Sao Paulo*, 10 (1900), No. 11-12, pp. 795-799).

The yellow blight of potatoes (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, p. 683).—A brief quoted reference to this disease in Ireland is given. It is said to be accompanied by the stalk disease due to *Peziza postuma* and a root rot, neither of which is characterized.

Results of seed treatment of potatoes, H. KOCH (*Deut. Landw. Presse*, 27 (1900), No. 25, p. 295).—Seed tubers of 4 varieties were soaked for 24 hours in Bordeaux mixture before planting. The plants from the treated seed were 3 or 4 days later in coming up than the untreated, but were stronger and more healthy. A considerably increased yield, attributed to the treatment, is recorded for all the varieties.

On the prevention of potato rot, T. RITTER VON WEINZIERL (*Pub. K. K. Samen-Control Sta. Wien*, No. 199, pp. 3-5).—Spraying with Bordeaux mixture, 2 kg. copper sulphate, 2 kg. lime, and 100 liters water is recommended. Three applications are advised.

A nematode disease of rye, L. MANGIN (*Jour. Agr. Prat.*, 1900, I, No. 20, pp. 707, 708).—Describes a disease of rye due to *Tylenchus devastatrix*. The nematodes produce bulb-like enlargements of the roots. Rotation of crops is recommended as the most favorable means of prevention.

The life history of the tobacco nematode (*Heterodera radiculicola*) and its destruction, J. VAN BREDA DE HAAN (*Bul. Inst. Bot. Buitenzorg*, 1900, No. 4, pp. 1-10).

Notes on some galls produced by *Heterodera radiculicola*, M. MOLLIARD (*Rev. Gén. Bot.*, 12 (1900), No. 135, pp. 157-165, pl. 1, fig. 1).—Histological structures of galls on melons, colous, etc., are described.

Nematodes and ammonium salts, H. D'ANCHALD (*Jour. Agr. Prat.*, 1900, I, No. 20, pp. 711, 712).—Gas liquor and solutions of chlorid and nitrate of ammonia are said to be destructive to nematodes and the efficiency of the treatment lasts over 2 years. In order that all nematodes should be destroyed repeated applications, extending over several years, are recommended.

A new method of combating nematodes, H. WILFARTH (*Ztschr. Ver. Deut. Zuckerind.*, 1900, No. 529, II, pp. 195-204).

Demonstration of crown gall contagion (*Pacific Rural Press*, 59 (1900), No. 21,

p. 321, figs. 7).—Results of experiments by J. W. Toumey of the Arizona Station p. 458).

The scab disease of apples, pears, etc., and its treatment, WEISS (*Prakt. Bl. Pflanzenschutz*, 1900, No. 2, pp. 9–11).

Apple mildew, P. MAGNUS (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 8, pp. 253–255, figs. 2).—A discussion as to the specific relationship of the fungus causing apple mildew. The author doubts the occurrence of *Sphaerotheca mali* on apple trees. As a preventive the author speaks very highly of sulphur.

Means of protection from the so-called scab of pomaceous fruits, FRANK (*Sep. Arb. K. Gesundheitsamte, Biol. Abt.*, 1900, pp. 4, fig. 1).

Canker in fruit trees and its treatment (*Garden*, 57 (1900), No. 1478, pp. 197, 198).—A translation of an article treating of the attack of *Nectria ditissima* with suggestions for its prevention.

Leaf curl in peaches and nectarines (*Garden*, 57 (1900), No. 1479, p. 224, figs. 2).—Notes on *Erysica deformans* and suggestions for its prevention.

The shot-hole fungus (*Garden*, 57 (1900), No. 1480, p. 245, figs. 8).—Figures and describes the shot-hole fungus *Cercospora circumscisa*.

The biology and practical suggestions for combating hexenbesens in cherry trees, C. FREIHERR VON TUBEUF (*Arb. K. Gesundheitsamte, Biol. Abt. Leaflet* 4, 1900, pp. 4, figs. 4).

Witches brooms of Pinus sylvestris, A. W. BORTHWICK (*Trans. and Proc. Bot. Soc. Edinburgh*, 21 (1900), pp. 196, 197).

Some citrus troubles, H. H. HUME (*Florida Sta. Bul.* 53, pp. 147–173, pls. 6, figs. 5).—The author describes foot rot, scab, dieback, sooty mold, blight, melanose, and leaf spot—diseases of citrus fruits—and the injuries caused by the presence of lichens and moss upon the trees. Most of these diseases have been previously described in U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 8 (E. S. R., 8, p. 58), and the recommendations there given for the prevention of the diseases are repeated. The leaf spot disease is described as being slightly injurious to orange trees in some parts of the State. Large, somewhat circular, yellowish spots are noticed upon the leaves which are attributed to *Colletotrichum gloeosporioides*. Spraying trees with ammoniacal solutions or Bordeaux mixture is recommended. The injury done by lichens and moss (*Tillandsia usneoides*) is mentioned and the destruction of the lichens by spraying with strong Bordeaux mixture is recommended, while the moss may be removed by pulling it from the trees.

Collar rot or mal-di-gomma of citrus trees (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 660–668).—This disease, which is also commonly known as foot rot, is due to *Fusarium limonis*. The symptoms of the disease, conditions favoring its spread, means for its prevention, and history of the disease in Australia are given. The treatments recommended in U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 8 (E. S. R., 8, p. 58), are suggested as means for prevention.

Chlorosis of fruit trees, C. BOUILLOT (*Semaine Hort.*, 1900, pp. 23, 35, 36, 59, 60, 95).

Chlorosis of the vine, G. CURTEL (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 16, pp. 1074–1076; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 4, pp. 488, 489).—The physiological injuries inflicted by chlorosis of the grape have been investigated and it is shown that there is an evident weakening of the respiratory activity, a diminution in the proportion of gases exchanged, a diminution and final cessation of assimilation, and a great weakening of the functions of transpiration. The appearance of chlorosis and the lowering of the transpiratory function appear to be indissolubly connected.

Notes upon grape mildew, B. D. HALSTED (*Asa Gray Bul.*, 8 (1900), No. 4, pp.

78, 79).—Notes on the occurrence of *Plasmopara viticola* on grapevines at the New Jersey Experiment Station.

Potassium permanganate for grape mildew, A. SIMÉON (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 36, pp. 327, 328).—The addition of 50 gm. of permanganate of potash to a hectoliter of Bordeaux mixture is said to increase the efficiency of the fungicide when used in combating grape mildew.

Practical instruction in combating Peronospora, A. BIZZOZERO (*Istruzioni pratiche per combattere la peronospora*. Parma: Rossi-Ubaldi, 1900, pp. 29).

The California vine disease in Avellino, C. CASALI and T. FERRARIS (*Giorn. Vit. e Enologia*, 7 (1900), pp. 10, pls. 2).

Brown spot diseases of grapes and Plasmodiophora vitis, J. BEHRENS (*Sep. Weinbau u. Weinhandel.*, 1899, No. 33, pp. 2).

Grape scald, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 32, pp. 189, 190, pl. 1).—A serious affection of grapes is reported in which the fruit and leaves are injured. They present some of the characteristics of grapes in the last stages of black rot, white rot, etc. The cause of the trouble is thought to be the unusual hot weather. In some parts of France the grape crop which had been especially promising is very seriously injured and less wine will be made than last year.

Some injuries to grapes, E. BRINGUIER (*Mess. Agr.*, 5. ser., 1 (1900), No. 8, pp. 301-319).—Notes are given on a number of injuries to which grapes are subject, such as freezing, malnutrition, fungi, etc.

A stunted condition of grapevines, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 21, pp. 608-610, pl. 1).—Under the name "cabuchage" the author describes a diseased condition of grapes which he says is the same as court-noué—a stunted growth due to a number of causes.

Stunted growth (court-noué) of vines, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 24, pp. 694-703, pl. 1, figs. 12).—This is essentially the same article as that noted from another source (*E. S. R.*, 12, p. 260). The author states that variegation is a common accompaniment of the disease.

The successful prevention of grape diseases, W. SEELIG (*Proskauer Obstbau-Ztg.*, 1900, No. 4, pp. 49-51).

Diseases of chestnuts in Savoy and Valais, L. CRIÉ (*Bul. Min. Agr. [France]*, 19 (1900), No. 1, pp. 120-134).—A report on observations in these two regions on the various causes of disease and injury to chestnuts. A number of fungi are reported as causing great injury, among them are *Agaricus melleus*, *Torula citiosa*, *Phyllosticta maculiformis*, *Polyporus sulphureus*, etc.

A disease of Tradescantia, A. HOWARD (*Ann. Bot.*, 14 (1900), No. 53, pp. 27-38, pls. 2).—A rather severe attack of *Tradescantia zebrina* and *T. fluminensis* in green-houses is reported. Dead leaves and stems covered with fungi as well as numerous dark spots and patches were abundant. Among the fungi was a species of *Botryosporium*. Inoculation experiments were successfully carried on, the mycelium usually penetrating the epidermis, infection through the stomata being rarely observed. The affinities of the fungus are discussed at length. The species seems to agree with the descriptions of *B. diffusum*, a common saprophyte on rotten wood, branches, and leaves.

Natural methods for the prevention of plant diseases, H. MÜLLER-THURGAU (*Schweiz. Landw. Centbl.*, 1900, No. 3, pp. 69-86).

The use of copper sulphate and sulphur as preventives of plant diseases, J. BEHRENS (*Wchnbl. Landw. Ver. Baden*, 1900, No. 9, pp. 110-113).

The causes of injuries due to spraying with copper fungicides, WEISS (*Prakt. Bl. Pflanzenschutz*, 3 (1900), No. 2, pp. 13-15).

A competitive trial of spraying apparatus (*Ztschr. Pflanzenkrankh.*, 10 (1900), No. 1, pp. 42-53, figs. 12).—A report is given of the relative efficiency of a number of forms of spraying apparatus in applying various fungicides and insecticides.

ENTOMOLOGY.

Insect pests (*Agr. Bul. Malay Peninsula* [*Gard. and Forest Dept., Straits Settlement*], 1900, No. 9, pp. 252-279).—This article contains a general classification of the different groups of insects, with notes on the life history and habits of the members of each group, which are injurious in the Malay Peninsula.

An account of the bee-hawk moth (*Cephonodes hylas*) is given by A. L. Butler (pp. 263-266). This insect has caused great damage to coffee in the neighborhood of Petaling. The caterpillars strip the leaves entirely from the coffee trees and feed also upon the green berries after the leaves have been devoured. The transformation from the caterpillar to the pupal stage takes place just beneath the surface of the ground. The duration of the egg stage is from 5 to 7 days, of the larval stage from 4 to 5 days, and of the pupal stage from 10 to 14 days. The bee-hawk moth has few natural enemies which are sufficiently numerous to keep the insect in check. Only a few species of birds were observed feeding upon the caterpillars, and experiments with geckos indicated that these animals do not feed upon the insect.

Among the other economic insects upon which notes are given, the following may be mentioned: *Tinea granella*, *Attacus atlas*, the banana weevil (*Sphenophorus sordidus*), *Hylotoma victorina*, the coffee locust (*Cyrtacanthacris nigrovaria*), and white ants.

The sweet-potato weevil (*Cylas formicarius*), H. TRYON (*Queensland Agr. Jour.*, 7 (1900), No. 2, pp. 176-189, pls. 2).—This insect was first mentioned as injurious to sweet potatoes in Colombo in 1856. The distribution of the species includes Ceylon, part of the West India Islands, the southern portion of the United States, and various parts of Australia. Its first injurious occurrence in Australia was reported in 1886, since which time it has gradually become a formidable enemy to the cultivation of sweet potatoes. In some cases the insect causes the almost complete loss of a crop of sweet potatoes, and is a serious enemy to the crop in all cases, since even when the infestation is of the mildest sort, the presence of the larvæ and adults of the beetle may not always be detected in the sweet potato until it is cut open. The beetle and larva are found in the stems near the surface of the ground and later throughout the substance of the tubers. In the worst cases of infestations none of the tubers attain full development, but are pierced in all directions with the burrows of the weevils. The tunnels made by the larvæ in the tissue of the vines and tubers vary from 2 to 4 mm. in diameter and are not readily recognized until exposure to the air and water has brought about a discoloration of the tissue.

The author gives a description of the insect in all its stages. In Australia the sweet-potato weevil is found in its mature form at all

times of the year. Its food plants include the members of the morning-glory family, but the sweet potato is the plant which is most severely attacked. The mature insect feeds not only upon the stems and tubers, but also upon the succulent veins on the undersurface of the leaves, as well as the leaf petioles. The eggs are usually deposited along the course of the vine, but most frequently as near the base of the stems as possible. About 30 days are required for a complete life cycle, and there are several generations during the 6 months which constitute the life of the sweet-potato plant.

The author discusses the subject of the origin of this insect without coming to positive conclusions. The probability in the case is that the sweet-potato weevil originated in the same country with the sweet potato. It may therefore be considered as plausible that the sweet-potato weevil came from South America.

Severe repressive measures should be adopted against this insect, since its continued presence in a locality renders the raising of sweet potatoes practically impossible. Ordinarily, it is not the first generation of beetles which attacks the tubers, and the first indication of attack is in the stems. It is therefore advisable to cover the tubers more deeply so as to prevent, as far as possible, the beetles from gaining access to them. The author advises also that sweet potatoes be planted in flat culture without throwing the ground into furrows. The sweet potatoes will then be covered more deeply and be more inaccessible to the sweet-potato weevil. It is further advised that when it is found that the tubers are already infested, they should be disposed of as soon as possible in any way which will destroy the beetles contained in them. A bibliography of the literature of this insect is appended to the article.

Some scale insects upon Kansas grasses, E. A. POPENOE and P. J. PARROTT (*Kansas Sta. Bul.* 98, pp. 131-146, pls. 6).—The authors made a study of the species of Coccidæ which occur upon the native grasses of Kansas. Some of these grasses are important forage plants, and the injury caused to them by the attacks of the scale lice is considerable.

A table is given for the determination of the different genera of Coccidæ found upon the grasses of Kansas. These genera are *Eriococcus*, *Gymnococcus*, *Pseudolecanium*, *Antonina*, and *Aspidiotus*. A list is given of the species of these genera which occur in Kansas, with the name of the host plant in connection with each species. The number of species thus discussed is 8. Descriptions and brief notes are given of all these species, some of which are described as new.

The forest tent caterpillar, C. M. WEED (*New Hampshire Sta. Bul.* 75, pp. 107-132, figs. 14).—This bulletin is a revised form of Bulletin 64 by the same author (E. S. R., 11, p. 269), with additional notes concerning outbreaks of the insect in 1899 and notes on the bird

enemies of this insect. It is stated that the insect was more widely distributed and did more damage during 1899 than in any previous year in which record was kept.

On the authority of Miss Soule, orioles, blackbirds, cedar birds, vireos, robins, catbirds, and sparrows are reported as doing effective work in checking the ravages of the tent caterpillar. The same remedies are recommended which were outlined in Bulletin 64.

The selectmen of the town of Claremont offered a bounty of 5 cents a quart for the cocoons of this insect, and large numbers of cocoons are reported as having been collected.

The crop pest law, W. B. ALWOOD (*Virginia Sta. Bul.* 102, pp. 127-152, map 1).—This bulletin contains a copy of the act of the Virginia State legislature to create and maintain a State board of crop pest commissioners, approved March 5, 1900, and a copy of the rules and regulations adopted by the State board of crop pest commissioners for the prevention of the spread of injurious insects and plant diseases within the State. The purpose of the act is to enable a close supervision to be maintained over the nurseries of the State and shipments of nursery stock into the State from outside sources. Certificates of inspection will be required from all shippers outside of the State. The insect pests and plant diseases included under the Virginia law are San Jose scale, woolly aphis, peach yellows, black knot of plum trees, and fire blight of pear and apple trees.

Portions of Virginia Station Bulletin 79 and the latest report of the State inspector are slightly revised and republished in the present bulletin.

Progress in economic entomology in the United States, L. O. HOWARD (*U. S. Dept. Agr. Yearbook 1899*, pp. 135-156, pl. 1).—The author presents a historical account of the development of economic entomology in this country, in which the States of Massachusetts, New York, Illinois, and Missouri played an important part. In the line of insecticides, attention is called to the progress made in the use of Paris green and other arsenical compounds, kerosene emulsion, and hydrocyanic-acid gas.

A handbook of the gnats and mosquitoes, giving the anatomy and life history of the Culicidæ, G. M. GILES (*London: J. Bale Sons & Danielsson, 1900*, pp. 374, pls. 8, figs. 9).—This is a general treatise on mosquitoes, and treats of the following subjects: Position and terminology of the Culicidæ, anatomy of the adult mosquito, anatomy of the larvæ, characters of the larvæ of the various genera of Culicidæ, anatomy of the pupæ, life history, distribution, and classification of the family.

The second half of the work is devoted to a systematic account of the species of this family group and the following genera: Megarhina, Anopheles, Psorophora, Sabethes, Culex, Aedes, Corethra, and Mochlonyx.

Report on injurious insects and plant diseases in 1899, W. M. SCHOYEN (*Beretning om Skadeinsekter og Plantesygdomme i 1899. Christiania: Grondahl & Sons, 1900*, pp. 42, figs. 18).—This is the annual report of the government entomologist of Norway, and contains notes on a large number of injurious insects and fungus diseases, among which mention may be made of the following: *Aphis granaria*, *Thrips secalina*, ergot, *Charax graminis*, *Melolontha hippocastani*, potato scab, bacterial disease of tomatoes, cabbage-root maggot, *Psila rosæ*, onion maggot, oyster-shell bark-louse,

codling moth, *Cheimatobia brunata*, *Nematus ribesii*, *Lophyrus rufus*, *Chermes abietis*, and *Rhizotrogus solstitialis*.

Report of the division of entomology, L. BRUNER (*Nebraska Sta. Rpt. 1899*, pp. 45-49).—The work of the division has included experiments in controlling the native and migratory locusts in the State by means of fungus diseases. No beneficial results were obtained by this method. Individual farmers were urged to make thorough trials of the hopper dozer. Brief notes are given on the chinch bug, the fall army worm, and the Hessian fly.

Insect record for 1899, C. M. WEED (*New Hampshire Sta. Bul. 72*, pp. 59-74, figs. 11).—The author presents brief popular notes on the life history, habits, and means of combating the tent caterpillars, *Cucaccia cerasivorana*, plum curculio, fall webworm, white grubs, oyster-shell bark-louse, scurfy bark-louse, apple aphid, and the red-legged locust.

The storeroom beetle or bookworm (*Sitodrepa panacea*), S. F. AARON (*Sci. Amer.*, 82 (1900), No. 22, p. 347, figs. 4).—The author gives notes on depredations committed by this insect upon a number of substances, such as cork, chocolate, books, and herbarium specimens.

The destructive Hessian fly, M. V. SLINGERLAND (*Rural New Yorker*, 59 (1900), No. 2639, pp. 573, 574, figs. 3).—Brief notes on the appearance, life history, injuries, natural enemies, and means of combating the Hessian fly.

The grass thrips (*Anaphothrips striata*), H. T. FERNALD and W. E. HINDS (*Massachusetts Hatch Sta. Bul. 67*, pp. 12, pl. 1).—This bulletin is a simplified form of an article on the same subject in the Report of the Massachusetts Agricultural College for 1899 (*E. S. R.*, 12, p. 266).

The destructive green pea louse, W. G. JOHNSON (*Rural New Yorker*, 59 (1900), No. 2636, pp. 525, 526, figs. 2).—This insect is reported as injurious to red and crimson clover, as well as to field peas. Experiments were tried in planting peas in rows, which method rendered it possible to use the brush and cultivator method in the destruction of the pea louse. By means of a pine switch the vines were vigorously brushed just ahead of the cultivator, and the lice thus knocked upon the ground were buried to some depth. The operation may be repeated every 3 days during the height of the outbreak of the pea louse. The author states that no spraying method has been devised which will warrant the expense attached to the operation.

Lucern springtail or *Smynturus*, W. L. SUMMERS (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 1, pp. 18, 19).—This insect having proved injurious to lucern, experiments were conducted with various insecticide methods for combating it. Kerosene emulsion, Paris green, and London purple were tried without satisfactory results. Grazing sheep on affected land, harrowing, rolling, and flooding were tried with some success. The remedy which is considered most effective is the application of fresh gas lime. This substance is applied after cutting the lucern, 2 or 3 applications being necessary each year. About 700 to 1,000 lbs. per acre is required for each application.

A new method of combating the gypsy moth, RÖRIG (*Arb. K. Gesundheitsamte, Biol. Abt.*, 1 (1900), No. 2, pp. 255-260, figs. 2; *abs. in Deut. Landw. Presse*, 27 (1900), No. 74, pp. 915, 916, figs. 3).

The fruit moth (*Ophiuza lienardi*), C. W. MALLY (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 1, pp. 41-44).—According to the reports of correspondents this insect has caused injury to the following fruits: Apples, pears, plums, grapes, peaches, figs, oranges, guavas, bananas, pineapples, loquats, and medlars.

The San Jose and other scale insects, W. LOCHHEAD (*Ontario Dept. Agr.*, 1900, pp. 48, figs. 21).—This pamphlet contains a general account of the distribution, injuriousness, life history, habits, and insect enemies of the San Jose scale. The following treatments are recommended: Hydrocyanic-acid gas, whale-oil soap, crude petroleum, and diluted kerosene. Brief descriptive and economic notes are also presented con-

cerning the following scales: The Curtis scale, Forbes scale, Putnam scale, English walnut scale, oyster-shell bark-louse, scurfy bark-louse, and the New York plum scale.

A prospectus of an aphid fauna of Italy, G. DEL GUERCIO (*Nuove Relaz. R. Staz. Ent. Agr.*, 1. ser., 1900, No. 2, pp. 1-236, pl. 1, figs. 33).—This article contains detailed descriptive notes on a large number of species, together with tables for the identification of the species. In connection with the discussion of the more important economic species, notes are given on the injurious effects, natural enemies, and means of combating the Aphididæ.

Report of the spread of *Phylloxera vastatrix* in Austria during 1898-99 (*Bericht über die Verbreitung der Reblaus in Österreich in den Jahren 1898-99*. Vienna: Ministry of Agriculture, 1900, pp. 170, map 1).—This pamphlet contains the reports of fruit inspectors and horticultural experts on the condition of phylloxera in different parts of Austria. Numerous tables are given showing the localities infested, the extent of such infestations, and the rapidity of distribution of the phylloxera in different localities. During the year 1898-99, 190 new localities were found to be infested. The distribution of the insect progressed much more rapidly in 1899 than in 1898 on account of the dryness of the former year. The chief remedy against the phylloxera is bisulphid of carbon, of which increasing quantities are purchased from year to year. During the 2 years in question 12,376,000 American grape roots and scions were received for planting.

A new strawberry pest, M. V. SLINGERLAND (*Rural New Yorker*, 59 (1900), No. 2636, p. 526, fig. 1).—The author gives brief notes on the destructive habits of *Harpalus caliginosus* in attacking strawberries. The beetles have also been noticed feeding upon the seeds of ragweed. The author recommends the destruction of ragweeds in and near strawberry gardens and the use of the lantern trap for catching the adult beetles.

The small ermine moths (*Jour. Bd. Agr. [London]*, 7 (1900), No. 2, pp. 167-169, fig. 1).—*Hyponomeuta padella* and *H. eronymella* are briefly described. The caterpillars of this species hatch either in the autumn or spring and live gregariously in detached colonies inside of small tents. As remedies against these insects, hand picking, spraying with water under high pressure, kerosene emulsion, and tobacco decoction are recommended.

Contribution toward a monograph of the American Aleurodidæ, A. L. QUAINANCE (*U. S. Dept. Agr., Division of Entomology Bul. 8, tech. ser.*, pp. 1-64, pls. 8).—The author gives a systematic account of this family, including the genera *Aleurodes* and *Aleurodicus*. A detailed description is given of all species of this genera known to occur in America, with analytical tables for their determination. In connection with each species brief notes are given on the food plants.

The red spiders of the United States, N. BANKS (*U. S. Dept. Agr., Division of Entomology Bul. 8, tech. ser.*, pp. 65-77, figs. 16).—The author gives a brief account of the anatomical structures and habits of the genera *Tetranychus* and *Stigmaeus*, together with descriptions of a number of new species.

Forest insects of the Baltic provinces, F. SINTENIS (*Sitzber. Naturf. Gesell. Univ. Dorpat*, 12 (1899), No. 2, pp. 173-198).—The author gives lists of insects injurious to pine, fir, and various deciduous trees in the Baltic provinces, and also lists of insects in this region which attack animals and man in the forest. Brief notes are given on some of the more important of these insects. Among the beneficial insects the author mentions *Formica rufa*, *Pompilus viaticus*, *Ammophila sabulosa*, etc.

New parasites of borers, L. ZEHNTNER (*Meded. Proefstat. Suikerriet. West Java*, 1900, No. 46, pp. 13, pl. 1).—A species of *Elasmus* and a species of *Macrocentrus* were found parasitic upon *Scirpophaga intacta*. An undetermined brachonid species is found parasitic upon *Diatraea striatalis*, and another brachonid species upon *Sesamia nonagrioides*.

Insects that eat potato beetles, M. V. SLINGERLAND (*Rural New Yorker*, 59 (1900), No. 2637, p. 542).—Brief notes on *Perillus circumcinctus*.

Cost of fumigating an orchard of two hundred and seventy-five trees, W. J. ALLEN (*Agr. Gaz., New South Wales*, 11 (1900), No. 9, pp. 754-756).—Orange trees of medium size were fumigated with hydrocyanic-acid gas, at an average cost per tree of 9 cts.

Petroleum as an insecticide, G. DAVIS (*Rural New Yorker*, 59 (1900), No. 2637, p. 542).—The author relates experiences with kerosene oil sprayed upon peach trees at the time of budding. A serious injury to the tree resulted from the use of kerosene.

Use of nicotine as an insecticide, E. LAURENT and M. CORNU (*Mess. Agr., 5. ser., 1* (1900), No. 6, pp. 232-235).—A solution of nicotine was prepared with the following constituents: Water, $\frac{1}{2}$; nicotine, 1; methyl alcohol, 10; black soap, 10; carbonate of soda, 2. The insects upon which experiments with this solution were made included the caterpillars of *Bombyx neustria*, *Liparis dispar*, red spiders, bark lice, thrips, etc. The mixture was found to be exceedingly effective against caterpillars, and killed the common species of plant lice within 20 minutes.

Spray calendar (*Vermont Sta. Spec. Bul., Mar. 1900*, pp. 4, fig. 1).—Brief notes on formulae for the preparation of the more common insecticides and fungicides, with reference to their use in the treatment of common insect and fungus diseases.

FOODS—ANIMAL PRODUCTION.

The ideal ration for an army in the tropics, E. L. MUNSON (*Jour. Mil. Serv. Inst. United States*, 26 (1900), No. 105, pp. 309-346).—On the basis of a review of the literature of the subject and of personal observation, the author concludes that in the tropics less meat and similar nitrogenous food is required than in temperate or cold regions, while the proportion of other constituents of the diet, whose principal function is to yield energy, is also somewhat less. The daily dietary standard proposed for United States troops serving in the tropics is as follows: Protein, 100 gm.; fat, 65 gm., carbohydrates, 650 gm.; and fuel value, 3,491 calories. The diet suggested consists of such articles as fresh beef, bacon, fresh fish, flour, beans, potatoes and some other vegetables, rice, and sugar; in other words, of articles to which the soldier is accustomed and which are supplied under the existing regulations, the chief changes being in the quantities and combinations used. On an average, the 4 dietaries which are proposed as illustrations would furnish 109 gm. of protein and 3,375 calories.

The composition and physiological effects of beef broth, A. GAUTIER (*Dictet. and Hyg. Gaz., 16* (1900), No. 5, p. 273).—Abstract of an article published in *Le Bulletin Médical*. The composition of beef broth made by boiling 1 kg. of lean beef in 3 kg. of water, with and without the addition of salt and vegetables, is reported. When salt and vegetables were added the dry matter per liter of broth amounted to 27.3 gm. Deducting 7 gm. for the weight of the salt added, this was 1 gm. more than was obtained when the broth was

made with meat and water only. The principal deductions, as given in the abstract, follow:

"Contrary to what might have been thought, the common salt does not aid in dissolving meat in hot water, and . . . the vegetables furnish only 1 additional gram of dry extract per liter. . . .

"On account of the albuminoid substances it contains; on account of its sapid and aromatic substances which act by stimulating the sense of taste and the secretion of the stomach; in virtue of its creatin and xanthin bases, which, in small doses, play, like caffen (which itself belongs to the xanthin group), the rôle of cardiac and muscular tonics; owing to its organic phosphorized derivatives of lecethin; owing, finally, to its assimilable soluble phosphates, well-made beef broth is at once a food properly so-called, a stomachic which excites the gastro-intestinal secretions, and a general tonic. This suffices to explain the vogue which the good beef broth of our housewives has always had—and deservedly so, whatever may have been the prevailing theories."

Cattle foods, G. W. SHAW (*Oregon Sta. Bul. 62, pp. 13, 14*).—Analyses are reported of a number of feeding stuffs, including red clover (*Trifolium pratense*), *T. tridentatum*, *T. eriocephalum*, alsike clover (*T. hybridum*), *T. ciliatum*, *T. incarnatum*, *T. sp.*, meadow foxtail (*Alopecurus pratensis*), English rye grass (*Lolium perenne*), cheat (*Bromus secalinus*), vetch (*Vicia sativa*), sweet vernal (*Anthoxanthum odoratum*), spurry (*Spergula maxima*), orchard grass (*Dactylis glomerata*), tall oat grass (*Arrhenatherum avenaceum*), meadow fescue (*Festuca pratensis*), timothy (*Phleum pratense*), oat straw, wild barley (*Hordeum maritimum*), English fescue, native grasses (mixture), sachaline, sugar-beet pulp, salsify, wheat shorts, wheat, oats, and bran mixture (equal parts), oat chop, and wheat chop. The composition of a number of these materials is shown in the following table:

Composition of some Oregon clovers.

	Water.	Protein.	Ether extract.	Nitrogen- free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
<i>Trifolium tridentatum</i>	9.51	7.00	1.80	47.21	27.20	7.28
<i>Trifolium eriocephalum</i>	8.58	7.03	2.38	51.26	21.55	9.20
<i>Trifolium ciliatum</i>	10.29	10.06	1.94	45.93	22.20	9.58
<i>Trifolium incarnatum</i>	11.51	10.92	3.16	37.89	29.09	7.43
<i>Trifolium sp.</i>	10.05	10.66	3.04	55.02	12.07	9.16

Changes in the chemical composition of feeding stuffs during storage, H. WITT (*K. Landt. Akad. Handl. Tidskr., 39 (1900), No. 3, pp. 139-146*).—The author analyzed samples of feeding stuffs collected in Northern Sweden by Kellgren and Nilson from 1889 to 1894 (*E. S. R., 4, pp. 768, 971; 5, p. 808*) in order to ascertain what changes, if any, occur in the chemical composition of the air-dry fodders during prolonged storage. The samples were kept in the dark in tightly stoppered bottles. The average results of 2 sets of analyses of 25 samples of grasses and legumes showed that before storage the dry matter

contained 2.18 per cent of ether extract, 2.304 per cent of total nitrogen, and 0.296 per cent of nitrogen not digested by pepsin and trypsin. After storage the amount of ether extract was 2.03 per cent, total nitrogen 2.296 per cent, and nitrogen not digested by pepsin and trypsin 0.388 per cent. When treated with pepsin only, 0.472 per cent was not digested. A second series of analyses of 24 samples showed that on an average the nitrogen content was 2.409 per cent before storage and 2.4 after storage. The author's general deduction was that under the experimental conditions the nitrogen content of the feeding stuffs remained practically constant, while the digestibility of these constituents decreased somewhat. The percentage of ether extract present changed somewhat, but not regularly.—F. W. WOLL.

Analyses of commercial feeding stuffs, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul.* 78, pp. 165-186, fig. 1).—The commercial feeding stuffs collected in the fall of 1899 and analyzed in compliance with the State law regulating the sale of such materials, including 265 samples of cotton-seed meals, linseed-oil meals, gluten meals, gluten feeds, oat feeds, corn-and-oat feeds, provenders and similar products, wheat feed, poultry feeds, and animal meals.

"No cases of adulteration were found among the cotton seed, linseed, or gluten products, although certain brands do not grade as high as others and are open to improvement. There seems decided tendencies toward greater uniformity of quality with several brands. Many brands of oat feeds, dairy feeds, corn-and-oat feeds, provenders, and the like were found to contain a large quantity of oat hulls, more than they should carry were the goods made from 'pure grains ground together.' Such feeds are of inferior quality, and their purchase is of very doubtful advisability. The more highly concentrated feeds cost more, but for the purpose for which such materials are generally bought—to furnish protein—are much less expensive than low-grade goods."

For purposes of comparison, an average table is given, showing the average composition of the commercial feeding stuffs sold in New England markets, 1898-1900.

Skim-milk calves, H. M. COTTRELL, D. H. OTIS, and J. G. HANEY (*Kansas Sta. Bul.* 97, pp. 117-132, figs. 7).—The possibility of raising calves on skim milk suitably supplemented by other foods is discussed and a test with 13 calves (9 heifers and 4 steers) from scrub cows reported. Four or five days after birth the calves were taken from the cows. Skim milk was then gradually substituted for whole milk. The amount fed was increased, and finally reached 22 to 24 lbs. per head per day. In addition to skim milk, 4 of the calves were fed flaxseed made into a jelly with hot water and 4 were fed Blatchford's calf meal mixed with water to form a gruel. Some dry Kafir corn meal was also fed both lots. The remainder of the calves included in the test received dry Kafir corn meal in addition to skim milk. As the test progressed, corn meal was sometimes substituted for Kafir corn meal with all the calves. The heifer calves were given some

bran, soy-bean meal, oil meal, and ground oats in place of Kafir corn meal to prevent their becoming too fat, as it was the intention to use them for dairy purposes later on. All the calves were fed hay and later were pastured. The skim milk fed 6 of the calves was obtained from a creamery and was sterilized. During this process some water was added to the milk. At first the calves did not relish the sterilized skim milk on account of its peculiar odor, but they soon became accustomed to it and ate it with relish. The remainder of the calves were fed milk from a hand separator. All the milk was warmed before being fed. The authors state that no difference was detected in the condition of the calves fed the 2 sorts of skim milk. The skim milk was discontinued when the calves were 6 months old. The heifer calves then weighed on an average 375 lbs. and the steer calves 383 lbs. Those fed creamery skim milk gained on an average 250 lbs.; those fed hand separator skim milk 251 lbs., about 2,500 lbs. of skim milk being consumed in each case. The authors consider these figures remarkable, since the creamery skim milk contained 10 to 12 per cent of water added in the process of sterilizing. The calves fed the ration containing flaxseed meal gained on an average 1.55 lbs. per day; those fed the ration containing Blatchford's calf meal, 1.9 lbs.; while those fed only dry Kafir corn meal, in addition to skim milk, gained 1.82 lbs. Blatchford's calf meal cost \$70 and the flaxseed meal \$125 per ton. "Neither paid. And this experiment shows that such expensive feeds added to skim milk are not only unprofitable but useless, having practically no effect on the gain."

The average cost of a pound of gain the authors calculate to be 2.5 cts. The feeding was continued after weaning, the feeding stuffs used being Kafir corn, corn fodder, sorghum, and alfalfa hay. As yearlings the steers averaged 724 and the heifers 564 lbs.

Feeding steers; feed value of cotton seed and its products, J. H. CONNELL and H. C. KYLE (*Texas Sta. Bul. 55, pp. 131-214, pl. 1*).—*Feeding steers* (pp. 131-177).—Two tests with steers were undertaken to study the value of corn meal, oats, and hay when added to a cotton-seed meal and cotton-seed hull ration. The first test was made with 2 lots of 7 and 2 lots of 14 steers each. The test proper began December 24 and covered 140 days. For 100 days lot 1 was fed cotton-seed hulls and cotton-seed meal; lot 2, cotton-seed hulls, cotton-seed meal, and sorghum hay. For the remaining 40 days of the test, corn-and-cob chop was added to the ration of both lots. During the whole test lot 3 was fed cotton-seed hulls, cotton-seed meal, and corn-and-cob chop; and lot 4, cotton-seed hulls, cotton-seed meal, corn-and-cob chop, and oats. The amounts of feed consumed and the gains made by the different lots are given in full. Results are discussed for 100 days and for the whole period. The financial statement is based on cotton-seed hulls at \$3, cotton-seed meal at \$15, sorghum hay at \$6.

oats at \$14.48, and corn-and-cob chop at \$8.32 per ton. The cost of the gains made is also discussed on the basis of different rates for the feeding stuffs. At the close of the test the steers were sold in St. Louis at \$4.35 per hundredweight. The average results of the whole test are shown in the following table:

Results of first feeding test with steers.

	Weight at beginning of test.	Live weight gains.	Cost per pound of gain.	Shipping weight at station.	Shrinkage in shipment.	Dressed carcass.	Waste fat per steer.
	Pounds.	Pounds.	Cents.	Pounds.	Per cent.	Per cent.	Pounds.
Lot 1 (cotton-seed hulls, cotton-seed meal, and, during the last 40 days, corn-and-cob chop).....	745.49	243.86	4.000	927.50	6.5	57.19	37.0
Lot 2 (cotton-seed hulls, cotton-seed meal, sorghum hay, and, during the last 40 days, corn-and-cob chop).....	777.51	272.08	4.263	996.16	5.9	56.20	37.5
Lot 3 (cotton-seed hulls, cotton-seed meal, and corn-and-cob chop).....	749.35	273.46	3.639	965.49	6.7	57.43	33.3
Lot 4 (cotton-seed hulls, cotton-seed meal, corn-and-cob chop, and oats).....	737.45	263.49	3.837	943.23	6.6	56.75	33.8

The second test was made with 6 lots of 7 grade Shorthorn steers about 2 years old, and covered 140 days. After they arrived at the station they were fed for a preliminary period of 20 days, at first a ration composed of 12 lbs. of cotton-seed hulls and 3 lbs. of cotton-seed meal; later 18 lbs. of hulls and $4\frac{1}{2}$ lbs. of meal; and finally 20 lbs. of hulls and 4 lbs. of meal. During the test proper lot 1 was fed for 100 days cotton-seed hulls and cotton-seed meal; and lot 2, cotton-seed hulls, cotton-seed meal, and sorghum hay. At the end of this time corn-and-cob chop was added to the ration of both lots. During the whole test lot 3 was fed cotton-seed hulls, cotton-seed meal, and a small amount of corn-and-cob chop. Lot 4 was fed the same basal ration and a large amount of corn-and-cob chop. Lot 5 was fed a small amount of corn-and-cob chop and oats, and lot 6 a large amount, in addition to the same basal ration. The steers were sold in St. Louis and slaughtered. As in the previous test, the results are discussed in full. They are summarized in the following table:

Results of second feeding test with steers.

	Weight at begin- ning of test.	Live weight gains.	Cost per pound of gain.	Shipping weight at station.	Shrink- age in ship- ment.	Dressed carcass.	Waste fat per steer.
	Pounds.	Pounds.	Cents.	Pounds.	Per cent.	Per cent.	Pounds.
Lot 1 (cotton-seed hulls, cotton-seed meal, and, during the last 40 days, corn-and-cob chop)...	745.49	243.86	4.000	927.50	6.5	57.19	37.0
Lot 2 (cotton-seed hulls, cotton-seed meal, sorghum hay, and, during the last 40 days, corn-and-cob chop).....	777.51	272.08	4.263	996.16	5.7	56.20	37.5
Lot 3 (cotton-seed hulls, cotton-seed meal, and a small amount of corn-and-cob chop).....	750.71	281.43	3.422	977.21	7.3	57.55	34.3
Lot 4 (cotton-seed hulls, cotton-seed meal, and a large amount of corn-and-cob chop).....	748.00	265.50	3.856	953.78	6.6	57.31	32.3
Lot 5 (cotton-seed hulls, cotton-seed meal, a small amount of corn-and-cob chop, and oats)...	747.57	271.14	3.875	965.21	6.8	55.63	33.3
Lot 6 (cotton-seed hulls, cotton-seed meal, a large amount of corn-and-cob chop, and oats)...	727.33	255.84	3.800	921.25	6.5	57.88	34.3

The author's conclusions follow:

"Sorghum hay is more than equal to cotton-seed hulls, when fed with hulls and cotton-seed meal. The common practice of 'topping out' the hull and meal ration with corn chops is not so profitable as to feed the same amount of corn chops from the beginning. Steers fed 100 days only will make rapid gains on the several rations used.

"When corn chops is combined with hulls and meal, a feed of 2 lbs. of chops made more gain at less cost than when 4 lbs. of chops were used. Equal parts of oats, corn chops, and cotton-seed meal, combined with hulls, make an excellent ration. Corn chops and shelled oats are of equal value for fattening steers when fed with hulls and meal. Steers eating corn chops shrink largely in live weight, when shipped, if the chops is combined with hulls and meal."

Feed value of cotton seed and its products (pp. 178-214).—The composition and feeding value of cotton seed and its products are discussed at considerable length, the experience of the station and a number of individual feeders being cited in detail.

Pig feeding, J. S. NEWMAN and J. S. PICKETT (*South Carolina Sta. Bul.* 52, pp. 12, figs. 4).—Peanuts, sweet potatoes, and field peas were compared with corn with 4 lots of pigs each containing a sow and two barrows. Part of the pigs were 8 and the others 11 months old at the beginning of the test, November 23. In the 84 days of the test the pigs fed peanuts made an average daily gain of 4.32 lbs.; those fed sweet potatoes, 2.59 lbs.; those fed field peas, 3.34 lbs.; and those fed corn, 4.17 lbs. The amounts of the different feeding stuffs consumed per pound of gain were 6.7, 26.2, 6.7, and 9.2 lbs., respectively.

On the supposition that the yield of corn was 15, Spanish peanuts 90, cowpeas 10, and sweet potatoes 200 bu. per acre, and that pork was worth 5 cts. per pound, the authors calculate that (when fed to pigs) corn is worth \$6.97; peanuts, \$24.37; sweet potatoes, \$18.24; cowpeas, \$6.12 per acre.

In curing the hams of pigs fed peanuts there was a shrinkage of 22 per cent; in the case of those fed sweet potatoes and cowpeas, 27 per cent; and of those fed corn, 23 per cent. The mean atmospheric temperature was recorded during the test, but no variation in the gains made was attributed to this cause.

Development of the nutrition investigations of the Department of Agriculture, A. C. TRUE and R. D. MILNER (*U. S. Dept. Agr. Yearbook 1899*, pp. 403-414).—The development of the nutrition work of the Department is treated of and a brief historical account given of some of the American investigations which antedated this.

Cost and composition of bread in Oregon, G. W. SHAW (*Oregon Sta. Bul. 62*, pp. 9-12).—The cost and composition of 25 samples of bread collected in eastern and western Oregon are reported and the results compared with those of similar investigations in other regions. The composition of whole wheat and wheat flour from eastern and western Oregon is also given. The author notes that samples of bread made from eastern Oregon flour have a higher percentage of protein than those made from flour from the western portion of the State. This variation in protein content was also found in the flour from the different regions.

The gluten constituents of wheat and flour, and their relation to bread-making qualities, H. A. GUESS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 5, pp. 263-269).—The gluten and gliadin content of a number of samples of wheat is reported. Analytical methods are described.

A dietary study, G. W. SHAW (*Oregon Sta. Bul. 62*, pp. 17-20).—A dietary study which covered 1 week is briefly reported. It was made with a family consisting of 2 men and 3 women. The usual methods were followed. In calculating the cost, the different food materials were estimated at their usual cost in the Corvallis market. On an average the food actually eaten furnished per man per day 105 gm. of protein, 87 gm. of fat, 543 gm. of carbohydrates, and had a fuel value of 3,809 calories. The cost of the daily diet, including material wasted, was 17½ cts. per man per day.

Canned fish, A. RÖSSING (*Ztschr. Analyt. Chem.*, 39 (1900), No. 3, pp. 147-152).—It was found that the inside of tins in which sterilized codfish and lobsters had been preserved for several years was covered with a white coating, composed of stannic oxid, phosphoric acid, and iron. Imperfect sterilization has no connection with this corrosion, which seems to be due to the action of phosphates and ammonia contained in the codfish and lobster.—C. B. WILLIAMS.

Observations on the food supply of some West Indian Islands, F. WATTS (*West Indian Bul.*, 1 (1900), No. 3, pp. 270-281).—The principal vegetable foods in the Leeward Islands are described. An analysis of sweet potato flour is quoted, as well as the protein and energy supplied by the Leeward Island Prison diet and the diet of laborers. The latter figures are regarded as approximations only.

The food supply of the United Kingdom, Belgium, France, and Germany, R. F. CRAWFORD (*Miller's Gaz.*, 23 (1900), Nos. 43, pp. 532, 533; 44, pp. 543, 544; 45, p. 556; 46, pp. 568, 569; 47, pp. 581, 582; 48, p. 594; 49, pp. 604, 605; 52, p. 605).—A paper read at a meeting of the Royal Statistical Society, November, 1899. Many statistics are quoted.

Flesh foods, with methods for their chemical, microscopical, and bacteriological examination, C. A. MITCHELL (*London: Chas. Griffin & Co., Ltd.*, 1900, pp. 322, pl. 1, figs. 58; noted in *Jour. Soc. Chem. Ind.*, 19 (1900), No. 8, p. 788).—A laboratory manual.

Preservation of eggs (*Sci. Amer. Sup.*, 49 (1900), No. 1273, p. 20405).—A note on a method proposed by K. Reinhard which consists in dipping the eggs into sulphuric acid, thereby forming a coating of calcium sulphate on the shells.

Starch sugar and starch sirup and their use in the adulteration of "golden

sirup," FRÜHLING and A. RÖSSING (*Internat. Sugar Jour.*, 18 (1900), No. 2, pp. 317-319).—A discussion of adulteration and the food value of the adulterant.

Report on the olive oils of Tunis and the utilization of residues from oil making, MILLIAU, BERTAINCHAUD, and MALET (*Bul. Dir. Agr. et Com. [Tunis]*, 5 (1900), No. 14, pp. 21-62, figs. 7).—The report contains statistics of the amount of oil produced in Tunis, its value, methods of manufacture, analyses of different samples of oil, and composition and value of oil residues for feeding and for fertilizers.

Cider vinegar: Its solids and ash, R. E. DOOLITTLE and W. H. HESS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 6, pp. 218-220).—The authors report upon adulterated vinegars offered for sale which contain the normal amount of solids and ash. The results of investigation into their character showed that in one case the vinegar was composed of dilute acetic acid, glucose, and soda ash, and in another of acetic acid, boiled cider, and lime.

Baking powders, H. K. MILLER (*Florida Sta. Bul.* 52, pp. 131-143).—Baking powders of different classes are described and an examination of a number of samples of baking powder purchased in Florida reported.

Considering the poisonous properties of respired air, E. FORMANEK (*Arch. Hyg.*, 38 (1900), No. 1, pp. 1-66, fig. 1).—An extended review of previous work on this subject is given together with the results of a number of experiments. The principal deductions follow: In addition to carbon dioxide and water, the respired air from the lungs of man and animals contains no poisonous substance, with the exception of occasionally a little ammonia. This, however, is not a metabolic product, but a product of decomposition in the mouth, especially when the teeth are decayed or in the case of certain diseases. The presence of ammonia is sufficient to account for the poisonous properties which other investigators have found in respired air. The bad effects experienced in overcrowded rooms are discussed at some length. They are not regarded as due to any single cause.

The influence of certain alcohols, E. LABORDE (*Jour. Pharm. et Chem.*, 6. ser., 10 (1899), pp. 484-488; *Public Health*, 12 (1900), No. 12, p. 885).—A definite quantity of coagulated egg albumen was digested with acid pepsin or alkaline trypsin in the presence of 50 cc. of 20 and 5 per cent solutions of different alcohols, control experiments being made with water. It was found that isobutyl alcohol, glycerole, and malic acid, when present in small quantity, favored digestion with pepsin, and that methyl alcohol had a slightly accelerating influence. But digestion was markedly retarded by ethyl and propyl alcohol, lactic and tartaric acid, manitol, and glucose. When trypsin was the ferment used methyl and isobutyl alcohols, glycerole, and glucose increased digestion, and ethyl and propyl alcohol, lactic, malic and tartaric acids, and manitol diminished it.

The quantitative effect of pepsin, J. SCHÜTZ (*Ztschr. Physiol. Chem.*, 30 (1900), No. 1-2, pp. 1-14).—Experiments are described which have to do with the quantitative results obtained in artificial digestion by means of pepsin.

Concerning certain quantitative relations in pepsin digestion, HUPPERT (*Arch. Physiol. [Pflüger]*, 80 (1900), No. 8-10, pp. 470-526).—Investigations carried on by the author and E. Schütz are reported.

On the occurrence of proteolytic and amylolytic ferments in the contents of the human colon, J. C. HEMMETER (*Arch. Physiol. [Pflüger]*, 81 (1900), No. 4-5, pp. 151-166).—An experimental study of the ferments which are found in feces. Normal feces yielded an extract which digested dried pulverized blood fibrin and egg albumin in alkaline or neutral solution, while but little if any reaction took place in an acid solution. The amylolytic ferment found in the feces was active in an alkaline solution but not in an acid solution.

Concerning the organic phosphorus in feces from woman's milk and cows' milk, P. MÜLLER (*Ztschr. Biol.*, 39 (1900), No. 3, pp. 451-481).—Experiments are reported with children fed mother's milk and cows' milk, with a dyspeptic child fed cows' milk, with adult men consuming milk, with adult men consuming

beans, with nursing calves, and with a fasting dog. Special attention was paid to studying the ratio of nitrogen to phosphorus in feces. The author believes his experiments show that no more material rich in phosphorus is retained in the intestinal tract of normal nursing children when cows' milk is consumed than when woman's milk is consumed. Further, that the casein phosphorus is as well assimilated by adults on a moderate milk diet as by infants.

Cattle foods—miscellaneous analyses, H. H. NICHOLSON (*Nebraska Sta. Rpt. 1899*, pp. 38, 39).—Analyses of oat hay, corn fodder, old-process oil meal, potatoes, hog millet, dried peas, squaw corn, corn, wheat, rye, and corn germ.

Cotton seed, W. C. MACKENZIE (*Jour. Khediv. Agr. Soc.*, 2 (1900), No. 1, pp. 7-11).—A number of analyses of Egyptian cotton seed are reported and cotton seed in general discussed.

Linseed cake v. cotton cake, PATTERSON (*Farmers' Gaz.*, 59 (1900), p. 370).—A brief account is given of a comparison made with steers of cotton-seed cake and linseed cake with and without maize meal. Swedish turnips, hay and straw were fed in addition to the other feeding stuffs.

Dangers attending the use of grain as feed for stock, M. PELLERIN (*Jour. Agr. Prat.*, 1900, I, No. 23, pp. 816-818).—A general discussion.

The assimilation of iron, E. ABDERHALDEN (*Ztschr. Biol.*, 39 (1900), No. 2, pp. 193-270).—Experiments with rats, rabbits, guinea pigs, cats, and dogs are described.

Concerning the nutritive value of the heteroalbumoses of fibrin and the proteoalbumoses of casein, L. BLUM (*Ztschr. Physiol. Chem.*, 30 (1900), No. 1-2, pp. 15-44).—The author describes a number of experiments with dogs. Final deductions are not drawn. In the author's opinion further investigations will show that the products of digestion of the proteid molecule vary considerably, as his experiments indicate that certain albumoses (the proteoalbumoses of casein) are well suited to replace albumin, while others (the heteroalbumoses of fibrin) are less suited.

The development of the energy of motion of forward progression in a horse, P. LE HELLO (*Rev. Sci. Paris*, 4, ser., 13 (1900), No. 14, pp. 417-421, figs. 8).

Work of the breeders in improving live stock, J. CLAY, JR. (*U. S. Dept. Agr. Yearbook 1899*, pp. 627-642).—A general article giving historical and statistical data.

The principles of sheep breeding, J. S. H. SCHMIDT (*Queensland Agr. Jour.*, 4 (1899), No. 6, pp. 432-440; 5 (1899), Nos. 1, pp. 15-26; 3, pp. 270-275; 4, pp. 356-361; 5, pp. 443-452; 6 (1900), Nos. 1, pp. 5-8; 2, pp. 86-88; 3, pp. 172-176).—A general discussion of sheep and sheep management.

Economic value of goats (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 7, pp. 445-450).—The advantages of goat keeping are pointed out and the subject discussed in a general way.

Pigs and their management (*Queensland Agr. Jour.*, 5 (1899), No. 6, pp. 537-546; 6 (1900), Nos. 1, pp. 12-17; 2, pp. 93-100; 3, pp. 190-196; 4, pp. 267-276; 5, pp. 356-360).—An illustrated general article, summarizing some of the principal experiments on the subject.

Pig feeding experiments with Ohlendorff's meat meal, LILIENTHAL (*Deut. Landw. Presse*, 27 (1900), Nos. 40, pp. 510, 511; 42, pp. 519, 520).—From experiments reported in detail the conclusion is drawn that this meat meal can be profitably fed with proper precautions to young and growing pigs.

Queensland Agricultural College. Experimental pig feeding, J. MAHON (*Queensland Agr. Jour.*, 6 (1900), No. 5, pp. 365-368, pl. 1).—A comparison of boiled mangels and swill with boiled mangels and barley as a food for pigs showed that much better results were obtained with the former, the gain being 1.65 lbs. per head per day as compared with 0.06 lb. From a financial standpoint the addition of the barley was judged to be profitable.

Note on Bunsen's ice calorimeter, J. W. MELLOR (*Jour. Phys. Chem.*, 4 (1900), No. 2, pp. 135, 136, fig. 1).

DAIRY FARMING—DAIRYING.

Investigation in milk production, T. L. HAECKER (*Minnesota Sta. Bul.* 67, pp. 333-516, 550-556, figs. 30, dgmrs. 3).—This is a detailed report of dairy work covering a period of 3 years, 1894-1896.

System of keeping dairy records (pp. 334-340).—Illustrations from the milk and feeding records of the dairy herd are given and briefly discussed.

Herd record for 1894 (pp. 340-355).—The herd included 26 cows, 10 of which remained during the year. A full account is given of the management and record of the herd. Tables show the nutrients in the rations fed, the milk and fat produced, amount and cost of food consumed, etc. The 10 cows produced during the year on an average 4,909.7 lbs. of milk, containing 232.8 lbs. of fat, at a cost for food of \$29.72. The corresponding averages for 1893 were 6,407.7 lbs. of milk, 306.9 lbs. of fat, and \$37.82, cost of food.

Comparing wheat with barley and corn (pp. 356-365).—A ration containing 7 lbs. of wheat was compared with a ration containing 4 lbs. of barley and 3 lbs. of corn. In addition each ration contained the same quantities of bran, oil meal, timothy hay, and roots. The test was made with 12 cows, divided into 2 equal lots, and covered 4 periods of 2 weeks each. The rations were changed during alternate periods. The production of milk and butter fat was practically the same on the two rations. Slightly more digestible protein was required for the production of butter fat when the wheat ration was fed. The results are considered as showing no practical difference in the feeding value of ground wheat and ground barley and corn.

Comparing prairie hay with timothy (pp. 366-379).—Prairie hay and timothy hay were compared in rations containing grain and silage in addition. The test included 12 cows and lasted 8 weeks. The cows produced more milk but less butter fat on timothy hay than on prairie hay. When prairie hay was fed more dry matter was required for the production of milk and less dry matter for the production of butter fat than when timothy hay was fed. The general conclusion is drawn that the two kinds of hay have equal feeding value. The cost of production of 1 lb. of butter fat was 13.3 cts. on timothy hay and 11.5 cts. on prairie hay.

Herd record for 1895 (pp. 380-415).—A description is given of each of the 13 cows remaining in the herd during the year, together with a detailed account of the feeding and care of the herd. Results for the year are tabulated and discussed. The average production per cow was 7,418.6 lbs. of milk, containing 302.3 lbs. of fat. The average cost of food was \$28.47.

Eight cows of the herd were divided into 2 groups according to type. Group 1 contained cows spare and angular in conformation and having

deep bodies through the middle, and group 2 cows having a tendency to lay on flesh. The average production of the 4 cows in group 1 was 8,283.1 lbs. of milk and 445.97 lbs. of butter, and of the 4 cows in group 2, 6,817.6 lbs. of milk and 303.01 lbs. of butter. The cost of food was respectively \$30.82 and \$28.21.

The herd was increased during the winter of 1895-96, and a record of each cow from the beginning of lactation in the fall until the herd was turned out to pasture in the spring was compiled separately. Sixteen of the cows were divided into the 2 groups noted above. The cows in group 1 produced on the average 90.14 lbs. more butter than the cows in group 2 and at an average cost of 1.95 cts. less per pound.

Record of cows during period of lactation (pp. 416-440).—An individual record is given of 15 cows during a period of lactation. The average production of milk per cow was 7,227 lbs., and of butter 335 lbs. Variations in the amount and cost of butter production of individual cows are noted. A summary of the records of 12 cows classified according to the types mentioned showed an average production for group 1 of 6,720 lbs. of milk and 446 lbs. of butter, and for group 2 of 5,077 lbs. of milk and 229 lbs. of butter, the net return in the 2 cases being respectively \$38.11 and \$10.37.

Herd record for 1896 (pp. 441-457).—The herd contained 13 cows. The results for the year are summarized in tables. The average yield of milk was 7,454 lbs., containing 299.39 lbs. of fat and costing \$22.12 for feed. The herd was again divided according to type. The cows in group 1 gave an average yield of 8,580.3 lbs. of milk and 460.02 lbs. of butter, and the cows in group 2 6,248.9 lbs. of milk and 270.86 lbs. of butter. The cost of food in the two cases was respectively \$23.35 and \$22.11. In discussing results the author says:

“Five years of careful investigation in regard to the cost of production of butter between cows spare and angular in form, and cows carrying considerable superfluous tissue and having an inherited or acquired disposition to convert feed into flesh, show that in every instance the cow that carried the least flesh charged the least for butter, and just in so much as one cow was a little smoother and plumper than the other would her butter product cost more than that of the other.”

The records also indicate that cows of the spare and angular type remain in good service for a very much longer period than cows having a tendency to lay on flesh.

Variation in productive capacity of dairy cows and cost of production (pp. 458-481).—The author reviews work previously reported (E. S. R., 6, p. 925) and discusses at greater length the records of the herd noted above, especially as regards cost of milk and butter production, variation in the production of cows of different types, variation in the amount of dry matter required for the production of butter fat, amount of dry matter required for food of maintenance, and testing dairy cows.

"The records show that under the system of feeding it required from 8 to 9.6 lbs. of dry matter over and above that calculated for food of maintenance to produce a pound of butter by cows under normal conditions, but this might be materially reduced if the ration contained more grain and less roughage and the nutrients were adjusted to the exact requirements of the cow."

Comparing the cost of butter and meat production (pp. 482-495).—An account is given of an experiment conducted with 4 steers and 4 cows during the winter of 1896-97 to compare the cost of butter and meat production. The test covered 2 periods of 5 weeks each. The results are discussed at some length and summarized as follows:

"(1) With 100 lbs. of grain and an equal amount of hay and roots 4 steers made a gain of 24.19 lbs., and 4 cows with the same amount and kind of feed produced 12.04 lbs. of butter.

"(2) The 4 steers consumed feed valued at \$8.51, gained 424 lbs., being an average daily gain of 2.52 lbs., costing 2 cts. per pound and returning a pound gain for 8.2 lbs. of dry matter consumed.

"(3) The 4 cows consumed feed valued at \$11.84, yielded 255.42 lbs. butter fat, being a butter equivalent of 297.99 lbs. at a cost for feed of 3.97 cts. per pound, producing a pound of butter to 16.28 lbs. of dry matter consumed.

"(4) Type has not so much significance with a steer as it has with a dairy cow for the reason that a steer not of good type may be a large feeder and a good digester and convert all the food taken over his needs for maintenance into gain, while a cow not of the dairy type has the alternative of converting food either into milk or gain, and she may choose the latter at a time when the owner wants only the former.

"(5) Any sudden change in feeding or handling may cause a loss in weight or shrinkage in yield of milk and butter fat."

Variation in flow and percentage of fat in milk (pp. 496-516).—Tables show the daily and weekly variations in the yield and fat content of the milk of one cow during the first 4 weeks of lactation. Results for 4 years are summarized as regards the effect on the yield and fat content of milk due to changing from dry feed to pasture. The following table gives the data for the dairy herd for 4 years during the 8 weeks preceding and the 8 weeks following a change from stable to pasture, the 8 weeks in each case being divided into 4 equal periods:

Average record of dairy herd for 4 years before and after turning out to pasture.

	Total yield of milk.	Average fat con- tent of milk.	Total yield of fat.

**Dairy value of pea-vine silage compared with that of June pas-
ture, A. T. NEALE** (*Delaware Sta. Bul.* 46, pp. 9-12).—During the

winter 9 head of young cattle were fed a ration averaging 25 lbs. of pea-vine silage and 6 lbs. of hay, at an average daily cost of 3.5 cts. per head. The animals improved rapidly, showing that the ration was suitable for growing stock.

Three cows were fed during the winter a ration containing 50 lbs. of pea-vine silage and a grain mixture of corn meal and cotton-seed meal. The nutritive ratio was 1:4.75. There were no striking variations in the results. During one week in May green rye was substituted for the silage. The cows were then turned out to pasture, the grain ration remaining the same. "The change from silage to pasture indicated a possible gain of one-half pound of butter per cow per week." Owing, however, to the higher price of butter earlier in the season there was a net gain of 32 cts. per week from the 3 cows in favor of silage. The relative cost of silage and pasturage is considered, showing an excess against silage of \$2.91 per acre.

On the influence of heredity on the quality of cows' milk, G. CEDERHOLM (*Landtmannen*, 11 (1900), No. 10, pp. 157-161).—The author has accumulated evidence bearing on the question of the influence of heredity on the quality of a cow's milk, during systematic tests of the large dairy station herd of cows at Aalberga, Sweden, for a period of 5 years. Appreciating that the system of feeding, time of calving and of lactation, age of cows, and other factors may render uncertain comparisons of the average quality of the milk of different generations, the variations in fat content possibly due to these factors were first ascertained in studying the results of these tests. The system of feeding practiced and the method of handling the cows were as uniform as possible throughout the year, but marked differences were nevertheless found in the milk produced by the whole herd during the different months of the year. The following table shows the average quality of the herd milk during each month, and also the average percentage of fat in the milk of cows that calved in the different months:

Average fat content of milk of cows calving in different months.

Month.	Herd milk.	Milk of cows calving in different months.
	<i>Per cent.</i>	<i>Per cent.</i>
January.....	3.62	3.48
February.....	3.54	3.48
March.....	3.53	3.45
April.....	3.45	3.40
May.....	3.37	3.42
June.....	3.27	3.41

August.....	3.61	3.40
September.....	3.57	3.53
October.....	3.56	3.47
November.....	3.70	3.55
December.....	3.66	3.48
Average for year.....	3.43	

Since the number of cows calving was about the same during the different months of the year, the changes found in the fat content of the herd milk can not be due to inequality in numbers, and it is seen that but slight variations occur in the average quality of the milk of cows that drop their calves in different months of the year.

The milk of cows that milked longer than 11 months was found to contain, on the average, between 3.6 and 3.8 per cent of fat.

No decided effect of age on the quality of milk was found, there being an extreme difference of less than 0.1 per cent in the average fat content of milk from cows from 3 to 13 years old; data for about 50 cows were included in each of the groups for the different years.

The author concludes that the data obtained furnish evidence as to the influence of heredity on the quality of the milk. Tables are given showing the average fat content of the milk of dams and their daughters for each of 5 sires used, a summary of which follows:

Increase or decrease in the average fat content of cows' milk as compared with that of their dams' milk.

Fat content of dams' milk.	Ossian 530.			Bill 717.			McDonald 628.			Dash 2d 660.			Dash 517.

a Number of daughters included.

Three of the bulls caused a marked improvement in the quality of the milk produced by their offspring, while in case of one bull (McDonald 628) there was an improvement in 7 cases and a deterioration in 5 cases (on the average an increase of 0.09 per cent), and Dash 2d 660 in all cases had daughters that gave poorer milk than their dams. This bull was out of a cow, Gullros 2d 551, that produced milk of a poor quality, the average percentage of fat in her milk being 3.06. In general the greatest improvement was observed in case of cows producing the poorest grades of milk. The data so far secured on this point are not considered sufficient to permit of definite conclusions as to the relative influence of the ancestors of a cow on the quality of milk produced by her, but they show, at any rate, that the bull exerts a decided influence for better or worse on the milk product of his progeny.—F. W. WOLL.

Galactase, E. VON FREUDENREICH (*Landw. Jahrb. Schweiz*, 14 (1900), No. 2, pp. 49-55; *Ann. Agr. Suisse*, 1 (1900), No. 3, pp. 77-84).—Experiments were conducted in duplication of some of the work reported by Babcock and Russell (*E. S. R.*, 10, p. 785). Skim milk to which 10 to 20 per cent of ether had been added was kept at room temperatures and also at 35° C. The soluble nitrogen in the milk at different periods from 1 to 8 months was determined in one series of experiments by the method employed by Babcock and Russell (heating with acetic acid) and in another series by the use of the Chamberland filter. In each series the nitrogen was determined in the filtrate by the Kjeldahl method. The results of the experiments confirm the work referred to.

Bacterial growth of *Tyrothrix tenuis* in skim milk and also in bouillon cultures was prevented by the addition of 10 to 12 per cent of ether. The addition of 20 per cent of ether to the milk as compared with 10 per cent increased the swelling of the casein which was precipitated in a flaky gelatinous form, but did not increase the soluble nitrogen. Milk heated to destroy the galactase and treated with ether showed no increase in soluble nitrogen. The presence of 0.3 to 0.5 per cent of lactic acid decreased markedly the action of the enzym. Formalin lessened the action of galactase and to a less extent that of pepsin and pancreatin, which had been added to sterilized skim milk. Dilution of the milk did not lessen the action of galactase. Heating to 85° destroyed it. Sterilized skim milk to which 20 per cent of ether had been added was inoculated with a few drops of an emulsion of spores of *Tyrothrix tenuis* and incubated at 35° C. Another sample was similarly treated, except that the bacterial culture was previously heated to 100° C. to destroy the enzymes present. There was an increase in the soluble nitrogen in the first case and none in the second, which was considered as showing that bacteria and their spores may contain proteolytic enzymes. Galactase would not pass through a porcelain filter.

The author does not believe that galactase plays the principal rôle in the ripening of cheese, especially Emmenthaler, but thinks that in rendering the casein soluble it possibly prepares for and facilitates the work of the bacteria which cause the ripening and produce the flavor.

Dairy development in the United States, H. E. ALVORD (*U. S. Dept. Agr. Yearbook* 1899, pp. 381-402, pls. 8, figs. 12).—This is an account of the development and present status of dairying in the United States. The progress made in the different periods of the nineteenth century is described. The establishment, features, and management of cheese and butter factories are considered. Notes are given on the introduction of dairy cattle and efforts at herd improvement. The centrifugal cream separator and the Babcock milk tester are described. The article closes with statistical information on the number of cows and quantity and value of dairy products.

Feeding dairy cows, T. L. HAECKER (*Minnesota Sta. Bul.* 67, pp. 517-549).—This

is a reprint in a somewhat revised form of an article previously noted (E. S. R., 10, p. 1095).

Feeding for milk, J. MAHON (*Queensland Agr. Jour.*, 7 (1900) No. 1, pp. 24, 25).

On the influence of the lactation period on the productive capacity of cows, F. W. WOLL (*Breeders' Gaz.*, 38 (1900), No. 9, pp. 239-240; *Hourd's Dairyman*, 31 (1900), No. 31, pp. 626, 627).—Variations in the yield and quality of milk during lactation are discussed and illustrations given from the records of the Wisconsin Station herd.

The quality of Scandinavian milk, R. H. WALLACE (*British Food Jour.*, 2 (1900), No. 22, pp. 276, 277).—A brief discussion concerning the average composition of milk in Sweden, Norway, and Denmark.

Variation in lactic acid bacteria in relation to fermentative power, N. P. SCHIERBECK (*Overs. K. Danske Vidensk. Selsk. Forhandl.*, 1900, No. 2, pp. 113-137).

Determination of the extent of milk adulteration, H. HÖFT (*Molk. Ztg.*, 14 (1900), No. 14, pp. 221, 222).—Directions are given for calculating the percentages of skim milk and water added to milk as adulterants.

Acidity of milk and the action of rennet, T. AUFSBERG (*Molk. Ztg.*, 14 (1900), No. 18, pp. 293, 294).—Notes are given on the determination of the acidity of milk, and 4 experiments are reported in which rennet tests were made of milk of different degrees of acidity. An increase in the acid content of milk of a low degree of acidity lessened in a much greater proportion the time required for coagulation than the same increase in the acid content of milk of a high degree of acidity.

Present views on the ripening of Cheddar cheese, J. MCCREATH (*Dairy*, 12 (1900), No. 142, pp. 281, 282).

Annual report of the experiment station for cheese making at Lodi, 1899 (*Ann. R. Staz. Sper. Caseif. Lodi*, 1900, pp. 110).—In addition to a general review of the work of the station during the year, this contains reports on several lines of investigation, including margarin in cheese, false "erborinatura" in Stracchino Gorgonzola cheese, method for determining the fat content of cream and calculating its equivalent in butter, the manufacture of casein for industrial purposes, cooperative dairying, white clover soils of Lombardy, and the deficiency of lime in meadow soils of lower Lombardy.

VETERINARY SCIENCE AND PRACTICE.

Remarks on the epidemiology and prophylaxis of malaria in the light of recent researches, A. CELLI (*British Med. Jour.*, 1900, No. 2041, pp. 301-306).—Man is the temporary host and the mosquito is the definite host of the malarial parasite. The species of mosquitoes which are capable of carrying the specific malarial parasites and of affecting man belong to the genus *Anopheles*. In Italy *Anopheles claviger*, *A. bifurcatus*, *A. superpictus*, and *A. pseudopictus* are injurious. It is improbable that species of *Culex* or other blood-sucking insects carry the malarial organism. *Anopheles* lay their eggs in slowly running or stagnant waters, where the larvæ of the genus *Culex* are seldom found. The larvæ offer slight resistance to desiccation. Freezing, especially if the ice be continuous, is unfavorable to the immature forms, as is also continued putrefaction in the water. In Italy mosquitoes begin to bite man about the second half of June and continue to do so until hibernation. The species of *Anopheles* do not

make the humming sound which is characteristic of *Culex*, and are, therefore, often present in rooms without being suspected.

The author discusses at some length the relationship of agriculture to malaria, and states his belief that the plowing of new soil does not contribute to the spread of malaria.

The fatal effect of green sorghum, R. S. HILTNER (*Nebraska Sta. Bul.* 63, pp. 71-84).—The use of sorghum as a forage plant in the State is becoming more extensive, and with its increase in importance for this purpose the number of deaths caused by feeding it increases. During the past year 144 fatal cases in cattle were reported.

The work reported in the present bulletin was undertaken for the purpose of determining, if possible, the nature and cause of these cases of poisoning. Frequent reports are made of bloat caused by the use of sorghum for forage. It has been supposed in some cases that the cause of death from using sorghum was to be found in the presence of parasitic fungi on the leaves of the plants. In a number of instances it has been believed by stockmen that plants were maliciously poisoned with strychnine, Paris green, or arsenic. Analyses made by the station of plants thus suspected indicated no trace of any such poison. Another suggestion made to explain poisoning by sorghum is that the plant takes up an unusual quantity of potassium nitrate during certain seasons or in certain localities. A number of samples analyzed indicated only a trace of nitrates. The most commonly believed theory for the explanation of poisoning by sorghum is that the plant under certain conditions develops a poisonous principle. The chemical department of the station undertook an investigation of this matter. In reports from stockmen it was noted that the symptoms were nearly uniform in all parts of the State and that the poisoning was not confined to animals of any particular age.

Samples of sorghum which had caused the death of cattle were analyzed in a fresh green condition and also after drying. Aqueous extracts were made and tested for chemical poisons, but none were found. No chemical compound was discovered which could be considered poisonous. It is of importance to note in this connection that the nitrogen content of the samples which were analyzed was not above the average. The opinion is somewhat widespread that the second growth of sorghum is more dangerous than the first growth. This may have been the experience of stockmen in some localities, but when all cases which have been reported from different parts of the State are considered it is found that the first growth is not always harmless and the second growth is not always poisonous. The majority of cases of poisoning reported were due to eating the second growth of sorghum. It should be stated, however, that the first growth is not fed in a green state to the same extent as the second growth, and this fact may account for the more extensive poisoning from second-growth plants.

The author concludes that the toxic effect of this plant which is manifested at certain times is not due to a poisonous principle inherent in the plant and is not peculiar to the second growth alone. The problem is, therefore, still unsolved.

Report on cooperative experiments in the treatment of hog cholera, A. T. PETERS, C. M. DAY, and C. H. WALKER (*Nebraska Sta. Rpt. 1899, pp. 64-90*).—The authors decided to test the value of inoculations with attenuated virus in the treatment of hog cholera. Twenty pigs weighing from 40 to 60 lbs. each were inoculated with 0.2 cc. of unattenuated virus, 2 pigs being inoculated each day. The first inoculation was made when the virus was 3 days old. Of this lot the first pig became sick 16 days after the inoculation, or 4 days after the period of incubation, while the last pig to show signs of hog cholera was taken sick 22 days after the period of incubation. It is therefore apparent that the infection was not the result of the artificial inoculation, but of hog-cholera germs present in the pens. Six pigs were inoculated with virus made according to the method of Dr. Billings. Thirty-one days after the first inoculation it was thought safe to inoculate a second time with 0.3 cc. of virus. The second inoculation was made July 25 and on August 1 all the pigs refused food. All of these pigs with but one exception ultimately died, and the exposure experiments with this one demonstrated that it had become immune to hog cholera.

The authors conducted experiments with virus prepared according to the Pasteur method of making blackleg virus. In general the spleen was selected as the organ from which the virus was prepared. May 3, 3 pigs were inoculated with this virus. One pig showed mild symptoms of hog cholera May 23 which continued to the 29th, when recovery apparently took place. May 31 these pigs were fed upon the viscera of a pig that had died of hog cholera. The inoculated pigs did not contract the hog cholera, while the check pigs all died of the disease.

Experiments were conducted in inoculating pigs with a mixture of antitoxic serum and virulent culture. The injection had no perceptible effect upon the pigs thus treated, and after 42 days they were exposed to hog cholera in a badly infected pen. All the pigs took sick within the period of incubation, thus showing that this method does not increase their resistance to the disease. Experiments with the Lorenz method gave entirely negative results. A modification of the Lorenz method was tried in which the pigs were first inoculated with virulent culture and later with a dose of serum. The pigs thus treated did not contract the disease until 28 days after receiving the inoculation. These pigs resisted infection 21 days longer than the pigs treated by the ordinary Lorenz method.

In experiments conducted for the purpose of determining the value of gradually increasing doses of antitoxic serum in the treatment of

hog cholera, 10 pigs were inoculated in this manner and after exposure to the disease did not become sick until after the period of incubation, and 1 animal showed complete immunity.

During the experiments conducted at the station it was noted that all efforts to secure perfect disinfection of pens were unsuccessful. A direct experiment was tried for the purpose of testing the disinfection of the pens. A pen which had been used for inoculating purposes was selected for this purpose. All refuse was swept up and burned and the floors were thoroughly soaked and washed in a strong solution of zenoleum, the walls and partitions being treated in like manner. The floor was removed and all refuse found below the floor was collected and burned. The floor was then covered with a thick coating of air-slaked lime. Two healthy pigs were placed in this pen July 30. Both of these pigs contracted the disease and died. Experiments conducted by the station with powdered virus indicated that this method is very efficacious if carried out under the best conditions. Such conditions, however, can not be found in old pens in which diseased hogs have been confined. The best conditions for conducting such experiments are to be found on the farm, in new pens, or on uninfected ground.

A note on serum diagnosis of glanders, BOURGES and MÉRY (*Arch. Med. Exper. et Anat. Path., Paris, 1. ser., 12 (1900), No. 2, pp. 182-188*).—The experiments of the authors on this subject included a study of the reactions of glanderous serum in horses which were not affected with glanders, in glanderous horses which exhibited clinical symptoms of the disease, and in horses which reacted to the mallein test but showed no clinical symptoms.

The general conclusions of these experiments may be stated as follows: If the blood of a horse agglutinates the glanders bacillus when diluted to the extent of 1 to 300 parts or more, the presumption is that the horse is glanderous. Agglutination in cases of less dilution does not necessarily imply the presence of glanders in the horse.

Some examples of the development of knowledge concerning animal diseases, D. E. SALMON (*U. S. Dept. Agr. Yearbook 1899, pp. 93-134*).—The author presents a brief historical account of the study of glanders, cowpox, horse pox, contagious pleuro-pneumonia of cattle, anthrax, blackleg, and Texas fever.

Administrative work of the Federal Government in relation to the animal industry, G. F. THOMPSON (*U. S. Dept. Agr. Yearbook 1899, pp. 441-464*).—An historical account is given of the quarantine and administrative work of this Department in combating contagious pleuro-pneumonia, Texas fever, sheep scab, hog cholera, blackleg, bovine tuberculosis, in the inspection of animals intended for slaughter, and in the inspection of meat.

Diseases of animals (*Rpt. Provincial Bd. Health Ontario, 1899, pp. 33, 34*).—Brief reports are given on cases of canine rabies, anthrax, and blackleg.

Report of the animal pathologist, A. T. PETERS (*Nebraska Sta. Rpt. 1899, pp. 25-28*).—The division of animal pathology has devoted attention to hog cholera, blackleg, calf cholera, ergotism, keratitis, cattle itch, foot disease, lumpy jaw, tuberculosis, and glanders.

Prophylaxis of infectious diseases of animals, NOCARD (*L'Ing. Agr. Gembloux*, 10 (1900), No. 11, pp. 657-676).—The author discusses in a general way methods of producing immunity by means of the inoculation of pure or attenuated virus and by serum therapy.

Phagocytosis and the blood-destroying leucocytes, C. ROUGET (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 13, pp. 307-309).—A controversial article on the problem of the nutrition of leucocytes. The author believes that the phagocytes derive nourishment preferably from dead material.

The structure of bacteria, FEINBERG (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 12-13, pp. 417-426, pls. 5).—The author made a study of a number of bacteria, among which may be mentioned the anthrax bacillus and the tubercle bacillus. It was found that in all cases a double stain could be used successfully on these organisms. As these stains were such as are usually employed in differentiating nuclear and protoplasmic substances in ordinary cells, it is concluded that bacteria possess a similar differentiation of the cell body.

Adaptation of pathogenic bacteria to different species of animals, T. SMITH (*Sep. Philadelphia Med. Jour.*, 1900, May 5, pp. 12).—In this paper the author classifies infectious diseases into 4 groups: Diseases common to man and animals and transmissible from one to the other; diseases common to man and animals but not transmissible; diseases transmitted from animals to man but usually not from man to man; and symbiotic relations, requiring 2 hosts for the life cycle.

The elimination of bacteria by means of the kidneys and liver, MÉTIN (*Ann. Inst. Pasteur*, 14 (1900), No. 6, pp. 415-419).—The organisms which were used in these experiments included *Bacillus subtilis*, *Staphylococcus aureus*, *B. anthracis*, and *B. prodigiosus*. Great difficulty was experienced in devising a method for drawing the urine directly from the bladder without allowing any blood to become mixed with it. The method adopted by the author consisted in exposing the bladder by laparotomy, cauterizing a small area of the wall of the bladder, and withdrawing the urine by means of a fine-pointed needle. The experimental animals were rabbits and guinea pigs. From a series of such experiments the author concludes that the kidneys and liver are impermeable to bacteria introduced into the organism by either intravenous or hypodermic methods. In cases where colonies of the micro-organism which were injected into the experimental animal developed in test tubes this micro-organism has become mixed with the bile or urine by means of a mechanical injury to the surrounding tissues produced in securing this substance for examination.

The rapidity of growth of the tubercle bacilli, P. RÖMER (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 20-21, pp. 705-709).—The author found during experiments in cultivating tubercle bacilli on different media that the most rapid growth was produced in a culture media in which the tubercle bacillus became covered with a slimy film.

The growth of the tubercle bacillus on acid brain culture media, M. FICKER (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), Nos. 14-15, pp. 504-511; 16-17, pp. 591-597).—During extensive investigations carried out by the author it was found that the tubercle bacillus made a more vigorous growth on acid culture media prepared from sputum, potatoes, blood serum, and various organs of the human and animal body than upon neutral or alkaline culture media prepared from the same substances. On acid brain culture media, consisting of agar or serum and brain substance, the tubercle bacillus seemed to find especially favorable conditions for rapid and intense growth.

The influence of the organism of cold-blooded animals on the bacillus of human tuberculosis, V. SION (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 20-21, pp. 710-720).—The author's experiments indicated clearly that the tubercle bacillus does not produce any of the characteristic lesions of tuberculosis in frogs. The bacillus does not become generally distributed through the body of these animals. The author maintains that the tubercle bacillus does not undergo any changes in

form or character while living for a considerable time in the body of frogs. It was impossible to note any such changes in the bacillus after remaining from 6 to 9 months in the organism of the frog. The pathological properties of the tubercle bacillus were not modified by this long sojourn in the frog. Experiments showed that bacilli which had remained 6 months in the peritoneal cavity of the frog caused death from generalized tuberculosis in the guinea pig at the usual time after inoculation.

Generalized tuberculosis in the horse, J. M. KNIPSCHER (*Tijdschr. Veeartsenijk en Veeteelt*, 27 (1900), No. 2, pp. 162-167).—A discussion of clinical symptoms and post-mortem findings.

The susceptibility of the ass to tuberculosis, V. GALTIER (*Jour. Med. Vet. et Zootech.*, 5. ser., 4 (1900), pp. 77-82, figs. 2).—It has long been known that the ass possesses a high resisting power to tuberculosis. During experiments which were conducted by the author it was found that of 11 asses which were inoculated in the jugular vein with tubercle bacillus all became infected, and 8 died. The other 3 recovered. The author concludes that, although the ass is very resistant to this disease, it may become infected naturally or experimentally.

The diagnostic and therapeutic significance of tubercle bacilli and other bacteria in sputum, L. BRIEGER (*Berlin. Klin. Wchnschr.*, 37 (1900), No. 13, pp. 272-274).—Notes on the frequency of tubercle bacilli in the sputum of tuberculous patients.

Tuberculin and their use, E. A. DE SCHWEINITZ (*Jour. Amer. Med. Assoc.*, 34 (1900), No. 15, pp. 898-900).—The author describes the difference in the methods of production and the nature of the old and new tuberculins. It is stated that the prospect of using the products of the tubercle bacillus freed from necrotic principles for the treatment of incipient tuberculosis is somewhat encouraging.

Tuberculin, and the early diagnosis of tuberculosis, B. FRÄNKEL (*Berlin. Klin. Wchnschr.*, 37 (1900), No. 12, pp. 255-258).—A discussion of the value of tuberculin in the practice of human medicine.

Morphological changes in anthrax bacillus during its dissolution by pyocyanase, R. EMMERICH and SAIDA (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 22-23, pp. 776-787, pl. 1).—The authors experimented with a proteolytic enzyme obtained from *Bacillus pyocyaneus*. A study was made of the effect of this enzyme upon a number of pathogenic bacteria, but the anthrax bacillus was finally selected as being the most favorable for this study. From inoculation experiments the authors believe it was demonstrated in the case of anthrax that a cure or artificial immunity is brought about by the dissolution of the specific bacteria by means of bacteriolytic enzymes. It has generally been believed that these enzymes exist only in the animal body. The authors were able, however, to produce the substances artificially.

A method of curing anthrax in horses, M. L. YUDIN (*Arch. Vet. Nauk.*, 30 (1900), No. 6, III, pp. 106-110).—The author gives a description of a method of curing anthrax in horses which was adopted in the Russian fifth army corps in 1830. Good success is reported from the application of this method.

New experiments in vaccinating reindeers, N. I. EKKERT (*Arch. Vet. Nauk.*, 30 (1900), No. 4, II, pp. 145-194).—The author conducted an extensive series of experiments in immunizing reindeer against anthrax. As a result of these experiments, it is concluded that it is possible to confer immunity against anthrax upon reindeer by means of vaccination. In the extensive tundra regions of the government of Archangel a method for producing immunity is required which can be applied on a large scale and in a rapid manner. The veterinary department is engaged in solving the problems presented by these peculiar conditions.

Malignant catarrhal fever of cattle, O. ÖPPENHEIM (*Berlin. Tierärztl. Wchnschr.*, 1900, No. 8, pp. 87, 88).—From a careful study of a number of cases of this disease

the author believes that many supposed cases of cerebral inflammation are identical with catarrhal fever.

Methods of fighting contagious pleuro-pneumonia of cattle, M. G. TARTAKOVSKY and E. P. DZHUNKOVSKI (*Arch. Vet. Nauk*, 30 (1900), No. 5, II, pp. 213-232).—A report of experiments with vaccine, methods for the treatment and prevention of this disease, together with a study of the micro-organism.

Tick heart water experiments, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 16 (1900), No. 11, pp. 682-687).—The author conducted experiments for the purpose of determining the means by which heart water is communicated from one animal to another. The results obtained from these experiments indicate that the transmission of the disease is brought about by the agency of the bont tick (*Amblyomma hebraeum*). The evidence obtained with regard to *Rhipicephalus evertsi* was not conclusive.

The plague, P. RUBAY (*Ann. Med. Vet.*, 49 (1900), No. 2, pp. 81-87).—A discussion of the antipest-serum treatment, of the relative degree of immunity possessed by different organisms toward this disease, and on the agency of various animals as carriers of the plague.

Tag-sore in Algeria, NOCARD (*Rec. Med. Vet., Paris*, 8. ser., 7 (1900), No. 4, pp. 86-90).—The author calls attention to the fact that this disease is apparently always present in Algeria, and believes that this is partly due to the fact that the disease assumes an unusually mild form in Algeria.

Enzootic occurrence of cancer in animals, R. BEHLA (*Berlin. Tierärztl. Wchnschr.*, 1900, No. 10, pp. 109-113).—The author gives a statistical account of the increasing prevalence of cancer in different countries. Attention is called to the many unsolved problems in connection with the etiology of malignant tumors in animals and man and to the importance of solving these problems as soon as possible.

Hog-cholera remedies, H. H. NICHOLSON (*Nebraska Sta. Rpt.* 1899, pp. 43-45).—Analyses are reported of a number of worthless patent remedies which have been proposed for the cure of hog cholera.

A case of chronic glanders in man, R. VON BARAZC (*Arch. Path. Anat. u. Physiol. [Virchow]*, 159 (1900), No. 3, pp. 491-520, pl. 1).—A bacteriological and pathological examination of a chronic case of glanders in man, together with a discussion of the literature of the subject and a bibliography.

The recurrence of glanders, LEBLANC (*Rec. Med. Vet. Paris*, 8. ser., 7 (1900), No. 4, pp. 80-83).—This article contains observations on the recurrence of glanders after apparent recovery or after mallein injections have failed to produce reaction. The author believes that mallein, although a very reliable agent for detecting glanders, is not infallible, since many cases have been observed where glanders has developed in horses after they had ceased to react to the mallein test.

The resistance of rabies virus to putrefaction, S. VON RATZ (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 24, pp. 825-827).—The author's experiments consisted in the production of acute cases of rabies in experimental animals and the inoculation of other animals with material taken from the brain of the first series of animals at periods of different lengths after death. The results indicate that rabies virus resists the action of putrefaction for a long time, but that its virulence is gradually modified.

The influence of injections of normal nerve substance on canine rabies and rabies toxine, V. BABES (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 16-17, pp. 464-468).—During the author's experiments on this subject it was found that injections of normal nerve substance had the effect of curing a large percentage of dogs which had been inoculated with attenuated rabies virus. A similar treatment was found to be beneficial to epileptic and melancholy people. It was shown, however, that although the development of rabies in dogs could be prevented by injections of normal nerve substance, this treatment did not confer immunity upon the dogs.

Poultry pests (*Agr. Gaz. New South Wales*, 11 (1900), No. 3, pp. 213-220).—Brief notes on the gapeworm, *Heterakis papillosa*, *H. inflexa*, diphtheritic roup, and a number of fleas, lice, and mites which infest poultry.

Favus in poultry, F. V. THEOBALD (*Jour. Bd. Agr. [London]*, 7 (1900), No. 1, pp. 17-19).—A brief account of the etiology, symptoms, and treatment of this disease.

An infectious disease of ostriches, MARX (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 24, pp. 822-824).—The author gives the details of the appearance of a bacterial organism found in the blood of ostriches suffering from an apparently new infectious disease. Experiments with this organism showed that it was not especially virulent for pigeons, but that small birds and mice were very susceptible to its action. Small birds contracted the disease when fed pure cultures of the micro-organism.

AGRICULTURAL ENGINEERING.

Irrigation and the associations syndicales, A. CHAVARD (*Ann. Agron.*, 26 (1900), No. 7, pp. 332-344).—This paper discusses the importance of irrigation, especially in the south of France, and recommends that the construction of reservoirs and canals and the division and distribution of water be placed in the hands of the agricultural syndicates which are organized in different parts of France mainly for the purpose of the cooperative purchase of fertilizers, seeds, agricultural implements, and occasionally for insurance against losses from hail and from the death of stock. An instance of such management, which has been attended with highly satisfactory results, is cited in detail.

Observations on Chavard's paper, P. P. DEHÉRAIN (*Ann. Agron.*, 26 (1900), No. 7, pp. 344-347).—In this note attention is called to the fact that France already has 22 large irrigation canals, many of which are very old, constructed at great cost and requiring 1,200,000 francs annually for their maintenance. These canals are capable of irrigating 254,641 hectares, but of this irrigable area only 51,122 hectares is actually irrigated. In other words, only one-fifth of the water supplied by the canals is used. While admitting, therefore, the importance of increased provision for irrigation in many localities, the author suggests that more efforts should be directed toward disseminating information regarding the need and profits of irrigation.

Experiments in grinding with small steel feed mills, F. H. KING (*Wisconsin Sta. Bul.* 82, pp. 37, figs. 24).—This bulletin records the results of something over 400 tests "to determine the rate at which feed for stock on the farm may be ground with several of the types of small steel mills now on the market; the power required to run them, and the approximate cost of grinding." The following mills were tested: (1) The O Aermotor grinder, used only with the 12-foot geared Aermotor windmill; (2) the N Aermotor grinder, designed for use with the 16-foot geared Aermotor windmill; (3) the No. 3 Appleton Prize Pulley Mill; (4) the No. 2 Bowsher; (5) the Giant; (6) No. 0 Ideal; (7) the No. 6 Smalley Monarch; and (8) the Vessot Little Champion.

"The powers used to drive the several grinders were (1) a 5-horsepower horizontal Fairbanks gas engine; (2) a 2½-horsepower Webster vertical gas engine; (3) a 16-foot geared Aermotor windmill, and (4) a 12-foot geared and roller-bearing Aermotor windmill. . . .

"The two engines were able to show very nearly their rated capacity by brake tests made upon the countershaft from which all of the mills except No. 1 were driven. An adjustable platform was provided upon which the several mills could be placed so as to be driven under every way like conditions. The fuel used by the engine was the city illuminating gas, costing \$1.25 per 1,000 cubic feet, and the amount used was measured with a meter placed next to the engines. The wind velocities under which the windmill trials were made were obtained with the aid of a Robinson anemometer. . . .

"In each trial an effort was made to regulate the feed so as, if possible, to fully load the power which was being used at the time. This, however, could not always be done with the 5-horsepower engine, especially when the coarser grades of meal were being ground. The usual practice was to start the mill with grain enough in the hopper to get it regulated and adjusted to the engine and, at a signal, as the last of this left the hopper, a weighed quantity of grain was placed in the mill and the exact time required to run it through noted, together with the amount of gas consumed or the miles of wind passing the windmill. . . .

"To secure a reliable basis of judgment for estimating the amount of work done in each grinding trial it was necessary to know the degree of fineness of meal produced as well as the amount ground in a unit of time. . . .

"In the trials of grinding corn an effort was made to produce four grades of meal, (1) very coarse, suitable for feeding sheep; (2) coarse; (3) medium, suitable for cattle, and (4) fine, suitable for hog feeding. . . .

"The first degree of fineness was such as would not pass a screen of 8 meshes to the inch; the second that passing a screen of 8 but stopped by one of 10 meshes; the third that which would pass a screen of 10 meshes but be stopped by one of 16 meshes to the inch, while the fourth grade was that passing the screen of 16 meshes to the inch."

With the O Aermotor grinder and 12-foot roller-bearing Aermotor windmill the rate of grinding in case of corn was "about 25 bu. per hour with a wind velocity of 31.8 miles, the meal being a little coarser than 'medium.' Corn and oats were ground at the rate of 410.3 lbs. per hour with the wind at 26.48 miles. With a wind velocity of 26.67 miles oats were ground at the rate of about 5.5 bu. per hour and rye at the rate of 15.35 bu. with the wind 25.35 miles. The rye was ground a little finer than 'medium' and the oats a little coarser."

From data recorded in this and in a previous bulletin (E. S. R., 10, p. 695) it appears that between October 1 and May 1—

"There were 87 days when a man could attend the mill and grind 10 hours with a wind velocity not less than 15 miles per hour, and much of the time higher than this. He should therefore be able to grind more than 46 bu. per day and on the average more than 100 bu. per week. The 87 grinding days, during the 7 months, places the grinding days, on the average more than two per week, and if it is supposed that this is twice too high it would still be possible on the average to take advantage of high winds during the working hours and grind about 50 bu. of corn, or 2,800 lbs. per week. Counting the man's time who tends the mill \$1 per day, the cost of grinding would be only about 3½ cts. per cwt.

"Some grinding of other grains than corn with the 12-foot windmill was also done,

but the number of trials was limited. With corn and oats, half and half by measure, the rate was 4,103 lbs. per 10 hours with a wind of 26.48 miles per hour. This is 93½ bu. per day of 10 hours.

"In grinding clear oats four trials were made with wind velocities of 19.46, 23.38, 24, and 26.67 miles per hour, and 10 hours' work at the observed rates would represent a grinding of 38.7, 50.2, 45.6, and 54.6 bu., respectively. At wind velocities of 25.35 and 25.18 miles per hour rye was ground at the rates of 153.4 and 136.8 bu. per 10 hours."

The observed work performed by the mill was found to agree fairly well with that calculated on the assumption that the effective energy of the mill increased with the square of the velocity of the wind for velocities between 7 and 36 miles per hour.

The results of the trials of the N Aermotor grinder and 16-foot windmill show "that up to 20 miles per hour of wind velocity the capacity of the 16-foot windmill was materially greater than that of the 12-foot wheel; but at higher velocities the reverse is true."

None of the other mills were as effective with the windmills as the grinders especially designed for them.

The results obtained with the other mills, using 2½ and 5-horsepower engines as the motive powers, are summarized in the following table:

The computed number of bushels of grain ground to a grade of 45 per cent of the finest degree in 10 hours, together with the cost of fuel for the same time.

Name of mill.	5-horsepower engine.		2½-horsepower engine.	
	Bushels per 10 hours.	Cost of gas per 10 hours.	Bushels per 10 hours.	Cost of gas per 10 hours.
Corn:				
Appleton.....	254.6	\$1.71	130.3	\$0.88
Bowsher.....	278.5	1.81	128.0	.89
Giant.....	255.4	1.67	110.3	.88
Ideal.....	203.6	1.72	114.6	.92
Monarch.....	190.8	1.74	104.3	.88
Vessot.....	311.1	2.04	114.0	.89
Average.....	249.0	1.78	116.6	.89
Corn and oats, average of all mills.....	239.3	1.94	95.0	1.01
Oats, average of all mills.....	113.4	1.66	70.2	.96
Rye, average of all mills.....	157.0	1.72	58.5	.78

"It will be seen from this table that as an average of all the grinding trials with the 5-horsepower engine the cost of fuel per day was \$1.775, and for the 2½-horsepower engine, \$0.885. This is at the rate of 3.55 cts. and 3.54 cts. per horsepower per hour for fuel where gas costs \$1.25 per thousand cubic feet.

"The average amount of corn ground per horsepower per hour was 4.822 bu., equal to 270 lbs., and this is 2,700 lbs. per horsepower for a 10-hour day."

It is estimated that at the rates ordinarily paid the grinding of feed for 30 cows for 200 days amounts to about \$57; the same amount of feed may be ground with a 5-horsepower engine, under the conditions obtaining in these trials, for about \$13.50.

It is stated that \$57 "is 10 per cent interest on a much larger sum than would be required to fit up an automatic grinding plant with the

12-foot windmill, the price of the mill and 90-foot tower being \$160, and the capacity of such a grinding plant would be many times what would be demanded for a herd of 30 cows."

Silage and the construction of modern silos, F. H. KING (*Wisconsin Sta. Bul. 83, pp. 68, figs. 28*).—This bulletin discusses the value of silage as a feeding stuff; the essential conditions for preserving silage; the details of construction, cost, and efficiency of silos of different kinds; the selection and culture of crops suitable for ensiling; the preparation of silage; and the losses which occur in the preparation and feeding of silage.

"The problems of silage and silo construction have been studied now continuously for nearly 10 years. Two bulletins on the subject have been issued [E. S. R., 9, p. 393], and the present one embodies the knowledge which has been gained through a personal inspection of more than 200 silos, one-half of which were visited the past year, together with the conclusions regarding the essential conditions necessary to the making and preserving of good silage which have been reached through experimental studies extending over 7 years."

The cylindrical silo has generally proved most satisfactory. Various types of it, constructed of brick, stone, and wood, and lined and ventilated in different ways, as well as stave, pit, and rectangular silos, are described.

It appears that the unavoidable loss, *i. e.*, "the loss of feeding value which can not be prevented in the interior of a silo with air-tight linings when filled in the best practicable manner," may be as low as 2 to 4 per cent and in good practice need not exceed 4 to 8 per cent. An account is given of comparative experiments on this point with 3 types of silos—(1) a silo (with doors) made of Washington cedar staves accurately beveled and tongue-and-grooved, (2) a silo (without doors) made of 2 by 4 pine staves not beveled or tongue-and-grooved, (3) a galvanized iron cylinder with water-tight bottom and sides. The first and second silos were without bottoms, but stood on a level cement floor. The silos were filled with corn, cut in short pieces, at the same time and in the same way.

"When full, the silos were covered with 3 layers of acid and waterproof paper cut to a circle to fit closely, and upon this was placed a layer of sand about 5 in. deep. The silos stood in the warm plant house from August 29 until March 1, when they were opened."

The losses from the top layers of silage in the 3 silos were 50.75, 49.71, and 9.21 per cent, respectively; middle layers, 13.15, 14.98, and 7.01 per cent; bottom layers, 31.75, 26.16, and 0.51 per cent.

"The large losses from the bottoms of the two stave silos were due to air entering between the ends of the staves and the cement floor, and the greater losses from the [cedar stave] silo at both the bottom and top were due to the additional leaks about the doors.

"The metal silo was absolutely air-tight everywhere except at the top, and the three cases illustrate in an extremely forceful way how important it is to exclude the air from the silage.

"[In an 80-ton silo with galvanized-iron lining] there was lost only 6.38 per cent of the dry matter put into it in 1897, including that spoiled on the top and above the doors, but only 3.66 per cent of that below the 2 surface layers. Even in the small 1,580-pound metal silo the total loss, including that spoiled on top, was but 8.57 per cent, while the mean loss from the middle and bottom layers was only 5.3 per cent, and yet the silage had stood under the conditions of summer temperature and sun during 180 days.

"The observations with these silos prove that where the linings are strictly airtight very small losses need be sustained even in small silos and that when the air is not excluded the losses must increase in proportion to the openness of the silo lining."

Attention is called to the loss which occurs at the top of silos and that due to slow feeding.

"The data which have been collected show that silos left without covers of any sort from early September until March without being disturbed develop about 28 lbs. of spoiled silage per square foot of surface, while silos opened from the middle of October to the middle of December have an average of about 16 lbs. of spoiled silage per square foot of surface. These rates give 2,832 and 4,956 lbs. of loss for a silo 15 ft. in diameter, which is 1.4 and 2.5 per cent on 100 tons of silage. . . .

"Next to the losses due to the surface decay between filling and opening the silo the most serious one is that which is due to too slow feeding."

Rise and future of irrigation in the United State, E. MEAD (*U. S. Dept. Agr. Yearbook 1899*, pp. 591-612, pls. 5).—The topics discussed in this article are: Remains of ancient irrigation works, early irrigation in California, beginnings of modern irrigation, objections to corporate canals, water-right problems of the arid regions, the appearance and resources of the arid regions, present and future of irrigation, and the commercial importance of irrigation.

Progress of road building in the United States, M. O. ELDRIDGE (*U. S. Dept. Agr. Yearbook 1899*, pp. 367-380, pls. 4).—This is a review of the history and present status of road building in the United States and includes discussions of the following topics: Road methods of the first settlers, forced-labor system and roads of the early colonists, inauguration of turnpike roads by chartered companies, era of speculation and restoration of forced-labor system, national highways, introduction and development of steam railroads, difficulties of transportation and of travel, establishment of the Office of Public Road Inquiries, and progress of the movement in the United States for good roads.

Soiling, ensilage, and stable construction; being a revised edition of **Soiling, summer and winter**, F. S. PEER (*New York: M. F. Mansfield, 1900*, pp. 247, figs. 34).

STATISTICS—MISCELLANEOUS.

Annual Report of Minnesota Station, 1899 (*Minnesota Sta. Rpt. 1899*, pp. XX-610).—The report proper contains a financial statement for the fiscal year ended June 30, 1899, and a detailed review of station work during the year. Meteorological observations are given and Bulletins 60-64 of the station, treating of the following subjects, are reprinted: Beef cattle and swine (E. S. R., 11, p. 175); butterflies and moths injurious to our fruit-producing plants (E. S. R., 11, p. 170); wheat—varieties, breeding, cultivation (E. S. R., 11, p. 638); miscellaneous analyses (E. S. R., 11, p. 812); composition of tomatoes (E. S. R., 11, p. 843); proteids of wheat flour (E. S. R., 11, p. 872); black or summer rust of wheat (E. S. R., 11, p. 861); and Hessian fly, migratory locusts or grasshoppers (E. S. R., 11, p. 864).

Thirteenth Annual Report of Nebraska Station, 1899 (*Nebraska Sta. Rpt.*

1899, pp. 171).—This contains the organization list of the station; a report of the acting director on the staff, equipment, publications, and work of the station; a financial statement for the fiscal year ended June 30, 1899; and reports of the heads of departments, parts of which and several miscellaneous articles included in the report are abstracted elsewhere.

Agricultural experiment stations in the United States, A. C. TRUE (*U. S. Dept. Agr. Yearbook 1899*, pp. 513-548, pls. 3).—This is an account of the history organization, equipment, lines of investigation, and the general results of the work of the experiment stations, together with an account of early experimental work by agricultural colleges and other institutions, a discussion of the relations of the stations to the Federal Government and to several associations, and an account of the establishment and work of this Office.

Agricultural experiment stations in the United States, A. C. TRUE (*U. S. Dept. Agr., Office of Experiment Stations Circ. 44*, pp. 8).—A general review of the history and organization of the stations, with tables showing their location, directors, principal lines of work, and revenues for the fiscal year ended June 30, 1899.

Progress of agriculture in the United States, G. K. HOLMES (*U. S. Dept. Agr. Yearbook 1899*, pp. 307-334).—A general and statistical review of the development of agriculture in the United States, from the crude beginnings by the Indians until the present time.

Yearbook of the Department of Agriculture, 1899 (*U. S. Dept. Agr. Yearbook 1899*, pp. 880, pls. 63, figs. 33).—This consists of a general report by the Secretary on the operations of the Department during the year, 26 papers, noted elsewhere, reviewing for the most part the progress in agricultural science in the United States during the nineteenth century, and the usual summary of useful information on various subjects of interest to the farmer published in the form of an appendix.

Proceedings of the Agricultural Students' Association, 1899-1900 (*Nebraska Sta. Bul. 64*, pp. 85-107).—The proceedings of the association at its February meeting, including reports on home reading courses and on cultural experiments with corn (see p. 442), are given. Suggestions are made for experimental work to be carried on under the supervision of the heads of different departments of the college.

Agricultural education in the United States, A. C. TRUE (*U. S. Dept. Agr. Yearbook 1899*, pp. 157-190).—An outline of the origin and development of the system of agricultural education in the United States is given as an introduction to the article, the main purpose of which is "to present a general view of the different agencies for education in agriculture in this country as they exist at the close of the nineteenth century, and to indicate the directions in which the movement for the diffusion of knowledge on agricultural subjects among our people is tending."

Development of transportation in the United States, A. SINCLAIR (*U. S. Dept. Agr. Yearbook 1899*, pp. 643-663).—An historical account of the beginning and development of railroads in the United States, including a discussion of passenger traffic; a statistical review of the increase in population, agricultural production, and railroad mileage; a discussion of freight and passenger rates; and other topics connected with transportation.

Our foreign trade in agricultural products, 1890-1899, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 19*, pp. 62).—This is a statistical review of the foreign trade of the United States in agricultural products during the 10 fiscal years, 1890-1899.

Development of agricultural libraries, C. H. GREATHOUSE (*U. S. Dept. Agr. Yearbook 1899*, pp. 491-512, pls. 4, fig. 1).—This gives an account of agricultural books in college, general, and private libraries in the United States at the beginning of this century, traces the growth of agricultural libraries, gives a descriptive account of the agricultural libraries of the present time, and offers suggestions for permanent libraries for farmers.

A classification of the literature of agriculture enlarged from the decimal classification of Melvil Dewey, J. I. WYER (*Nebraska Sta. Rpt. 1899*, pp. 91-121).—"This classification of the literature of agriculture is the result of an attempt to arrange satisfactorily, in minute subject order, the literature on agricultural topics which has accumulated at the University of Nebraska library during the past 10 years." The classification includes nearly 600 heads, and is designed to provide for the most specialized agricultural literature, except in the department of floriculture. An index is added.

Bulletins of Alabama Station (*Index to Vol. VII, Buls. 101-107*, pp. 425-452).

The new agriculture of the tropics, G. E. W. (*Sci. Amer.*, 83 (1900), No. 5, p. 67).—A discussion of the agricultural products of the tropics and the improvement of soils and plants by the application of scientific methods.

Danish agriculture in 1899, R. SCHOU (*Tidsskr. Landökon.*, 1900, No. 1, pp. 1-26).

Crops in Denmark in 1899, K. HANSEN (*Tidsskr. Landökon.*, 1900, No. 2, pp. 46-74).

Agricultural syndicates in France, H. W. WOLFF (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. 2, pp. 252-262).—Popular article pointing out the benefits to French agriculture of the formation of cooperative societies among the farmers for the purchase of seeds, fertilizers, farm implements, feeds, etc., needed by farmers, and for the sale of farm products.

NOTES.

COLORADO COLLEGE AND STATION.—Carl H. Potter, assistant in horticulture, has been granted leave of absence for one year on half pay. Mr. Potter will remove to the vicinity of Grand Junction, and will there act as field agent and investigator for the agricultural college. The resignation of C. F. Mergelman as florist has been accepted, to take effect January 1. Joseph Lownes, who has for two years been assistant chemist at the station, died December 9. A short course of two or three weeks for canal superintendents and State water commissioners has been authorized by the State board of agriculture, to be given in the spring. This is intended to give them fuller knowledge of their duties in the distribution of water, which is an important part of their work.

GEORGIA STATION.—This station is erecting a greenhouse in addition to the propagating house already in use, and will undertake investigations and experiments in winter forcing of vegetables, etc., and such lines of biological work as require such facilities.

IOWA COLLEGE AND STATION.—The main building of the agricultural college, one of the oldest on the campus, was destroyed by fire December 8, 1900. The building contained the botanical department of both the college and station, which suffered heavily. The Parry herbarium was saved, except the duplicates, which were nearly all burned. A part of the grass collection was saved and a few of the other specimens. The general collection contained about 80,000 specimens, more than 50,000 of which were burned, besides several thousand duplicate specimens. This collection included many Western plants, representing four years of collecting, and sets of plants from Porto Rico, Cuba, and Mexico. Much of the library of the botanical department, as well as the private library of the botanist, was destroyed, and most of the microscopes and other apparatus were burned. A manuscript on the grasses of the State and one on thistles were also lost, together with a number of smaller papers ready for publication.

KANSAS COLLEGE AND STATION.—Tait Butler has been elected to the chair of veterinary science made vacant by the resignation of Paul Fischer.

NEW MEXICO COLLEGE AND STATION.—All departments of the college and station were represented in the exhibit made at El Paso during the midwinter carnival in January. The biological department of the college has received a large amount of zoological material, principally for study and dissection by students, which makes its equipment in these lines by far the best in the Territory. One of the finest wild roses in America has been discovered and described by the station botanist, having been found growing wild in the Organ and Sacramento mountains. Not long since a small weed, growing profusely on the mesas and in the valleys, was found to possess qualities which apparently make it valuable as a substitute for litmus, and it is more than possible that this little weed can be demonstrated to be valuable to commerce.

TENNESSEE UNIVERSITY AND STATION.—M. Jacob, V. M. D., a graduate of the veterinary department of the University of Pennsylvania and formerly house surgeon of that institution, and more recently connected with the meat-inspection service of the Bureau of Animal Industry of this Department, has been appointed instructor in veterinary science at the university and consulting veterinarian of the station.

NATIONAL IRRIGATION CONGRESS.—The ninth annual session of the National Irrigation Congress was held in Chicago, Ill., November 21-24, 1900. There were in

attendance about 200 delegates, including several representatives of this Department. Elwood Mead, expert in charge of irrigation investigations of this Department, presided and delivered the presidential address. In this he briefly reviewed the origin and the history of the Irrigation Congress, and discussed the relation of the great irrigation problems to the States and to the nation. He advocated the union of land and water under one control, and he pointed out that many of the great irrigation questions were not solely State questions but that "there are certain matters which only the nation can deal with." The settlement and development of the irrigated region "requires new laws for the distribution of the irrigable lands to the people" and laws for the division of the waters of rivers between the States. "The work which lies before us is beyond the means of local effort or individual enterprise. The adjustment of the diverse and conflicting interests of individuals, communities, and different States requires not only wise national laws, but administrative ability of high order in their execution. The framing of these laws is a task which ought not much longer to be deferred."

Special prominence was given in the session to the question of the storage of water. Resolutions were adopted urging upon Congress that "national appropriations commensurate with the magnitude of the problem should be made for the preservation of the forests and the reforestation of denuded areas as natural storage reservoirs, and for the construction by the National Government, as part of its policy of internal improvement, of storage reservoirs and other works for flood protection, and to save for use in aid of navigation and irrigation the waters which now run to waste, and for the development of artesian and subterranean sources of water supply. The waters of all streams should forever remain subject to public control, and the right of the use of water for irrigation should inhere in the land irrigated, and beneficial use be the basis of measure and the limit of the right." The work of the various branches of the National Government in the investigation of problems relating to irrigation was commended, and the necessity of providing liberal appropriations for this important work was emphasized. The officers chosen for the ensuing year are as follows: Thomas F. Walsh, Washington, D. C., president; J. B. Prince, New Mexico, first vice-president; F. B. Thurber, New York, second vice-president; H. B. Maxon, secretary.

MISCELLANEOUS.—There has been begun by Dr. Alexander Ramsey a bibliography, guide, and index to the bacteria. It is published in *The Scientific Roll and Magazine of Systematized Notes*, the first number of which appeared in October, 1900. The conductor of the magazine requests all authors on bacteriological subjects to communicate with him in care of R. L. Sharland, publisher, 38 Churchfield Road, Acton, London, W., England.

E. Rathay, professor and director of the Oenological and Pomological Station of Klosterneuburg, Austria-Hungary, died September 9, 1900, in his fifty-sixth year.

Prof. A. B. Frank, professor of botany in the Agricultural High School at Berlin and director of the biological division of the imperial board of health, died recently at the age of 61 years.

Thomas A. Williams, assistant chief of the Division of Agrostology of this Department, died suddenly at his home December 23, 1900, of heart trouble. Professor Williams had been connected with the Division of Agrostology since 1896, and through his ability and industry had risen to an important place in its activities. He was widely known among botanists and station workers, by whom he was regarded as an efficient and untiring worker in his chosen field, and was highly esteemed.

W. P. Cutter, for several years past Librarian of this Department, has resigned to accept a position in the Congressional Library. He has been succeeded by Miss Josephine A. Clark, formerly assistant Librarian.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The EDITOR and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. 6.

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Comparative methods of determining nitrogen in nitrates, L. von Wissell.....	510
The determination of perchlorates in potassium and sodium nitrates, N. Blattner and J. Brasseur.....	510
Method of determining chlorid, chlorate, and perchlorate in the presence of each other, N. Blattner and J. Brasseur.....	510
Experiments in the determination of cell-wall material, hemicelluloses, and cellulose in plants, A. Kleiber.....	511
The relation of the reducing power of normal urines to the amount of certain nitrogen compounds present, J. H. Long.....	512
The nucleic acid of the embryo of wheat and its protein compounds, T. B. Osborne and G. F. Campbell.....	512
The proteids of the egg yolk, T. B. Osborne and G. F. Campbell.....	513
The protein constituents of egg white, T. B. Osborne and G. F. Campbell.....	514
On the chemical properties of the fat in Norwegian creamery butter, F. H. Werenskiöld.....	515
Nut oils, L. H. Merrill.....	516
Limestones, petroleum, etc., A. M. Peter and H. E. Curtis.....	516

BOTANY.

	Page.
Twigs of common trees and shrubs, F. H. Hillman	519
A study of the root systems of cultivated plants grown as farm crops, A. M. Ten Eyck.....	516
Sugar-producing plants, L. Geschwind.....	518
Hydrocyanic acid in plants, M. Soave.....	518
Soil inoculation for promoting the growth of legumes, F. T. Shutt.....	518

METEOROLOGY.

How to prevent hailstorms, P. N. Kritski.....	520
Monthly Weather Review, Vol. XXVIII, Nos. 4-6.....	520
Meteorological summary for 1898, V. E. Muncy.....	521

AIR—WATER—SOILS.

Mineral waters, A. M. Peter and H. E. Curtis.....	526
Field operations of the Division of Soils, 1899, M. Whitney et al.....	522
A study of the physical properties of clay as related to soil structure, V. H. Davis.....	525
The moisture of the soil under the pine forest of the Khrenov estate, G. Morosov.....	525
Drainage for alkali spots, C. E. Mead.....	526
Description of a soil map of the Connecticut Valley, M. Whitney.....	527

FERTILIZERS.

On the availability to grass of nitrogen in form of nitrate of soda, cotton-seed meal, and fine, hard bone, E. H. Jenkins and W. E. Britton.....	527
On the availability to Hungarian grass of nitrogen in form of nitrate of soda, cotton-seed meal, and raw, boiled, and steamed bone, E. H. Jenkins and W. E. Britton	528
On the availability of the nitrogen of hard raw bone as affected by applications of slaked lime, E. H. Jenkins and W. E. Britton.....	528
The comparative value of nitrate of sodium and sulphate of ammonium as manures, R. Warington.....	529
Niter earth, wood ashes, and phosphatic material, A. M. Peter and H. E. Curtis	530

FIELD CROPS.

Field experiments at the experiment farm at Lauchstädt in 1897 and 1898, M. Maercker	531
Field experiments with farm crops, W. Saunders, J. H. Grisdale, W. T. Macoun, R. Robertson, S. A. Bedford, A. Mackay, and T. A. Sharpe.....	535
Corn culture in North Carolina, B. Irby	538
Crops for alkali soils, C. E. Mead.....	538
Grasses and forage crops, C. A. Keffer.....	538
Kentucky forage plants—the grasses; analyses of some Kentucky grasses, H. Garman and A. M. Peter.....	547
Drought-resisting forage plants at the cooperative range experiment station, Highmore, S. Dak., J. H. Shepard and D. A. Saunders	547

	Page.
Results of manuring, C. E. Mead.....	539
Sugar-beet investigations, J. D. Towar.....	540
Sugar beets in 1898, R. H. McDowell and N. E. Wilson.....	541
Sugar beets in 1899, N. E. Wilson and R. H. McDowell.....	542
Analyses of sugar cane and sugar beets, A. M. Peter.....	547
On the effects on tobacco of shading and the application of lime, W. C. Sturgis	542
Experiments in curing and in fermenting wrapper leaf tobacco, season of 1899, E. H. Jenkins.....	544
The area of leaf surface on the topped tobacco plant, E. H. Jenkins.....	547
Physiological studies on Connecticut leaf tobacco, O. Loew.....	545

HORTICULTURE.

The report of the horticulturist, L. C. Corbett.....	558
Fruits, vegetables, flowers, and ornamental shrubs at the Experimental Farms in Canada, W. T. Macoun, W. S. Blair, S. A. Bedford, A. Mackay, and T. A. Sharpe	548
On the use of commercial fertilizers for forcing-house crops, E. H. Jenkins and W. E. Britton.....	549
Tomatoes, F. S. Earle	551
Watermelons and muskmelons in South Dakota, N. E. Hansen and W. S. Thornber.....	552
The apple orchard, J. C. Whitten	553
A chemical study of the apple and its products, C. A. Browne, jr.....	554
Observations on the fertilization of peach orchards, E. H. Jenkins.....	558
Plums—a comparison of varieties, W. J. Green.....	557
An observation of the effects of nitrogenous fertilizers on California privet, W. E. Britton.....	557
Note regarding the effect of the winter upon chestnut grafts and scions, W. E. Britton	558

FORESTRY.

Forest trees and shrubs, A. Mackay	559
Importance of forest tree growing, D. C. Burson.....	559
The forestal conditions and silvicultural prospects of the coastal plain of New Jersey, J. Gifford	560
Forest planting in Norway, Deinboll	560
Conifers at Murthly Castle, Scotland	560

SEEDS—WEEDS.

Influence of varying the temperature on the germination of seeds, W. Kinzel.....	563
Tests of the vitality of vegetable seeds, E. H. Jenkins	563
Testing grass seed, C. D. Woods	565
Spraying for the destruction of mustard, F. T. Shutt.....	564
Results of experiments on the spraying of charlock, P. S. Foulkes.....	564

DISEASES OF PLANTS.

Some important fungi and fungicides, C. O. Townsend.....	572
Miscellaneous notes on fungus diseases, W. C. Sturgis	565
A contribution to the knowledge of cereal rusts, H. Klebahn.....	567
Parasites of wheat, L. Mangin.....	567
On the so-called "grain" of wrapper tobacco, W. C. Sturgis	567

	Page.
Further notes on the pole burn of tobacco, W. C. Sturgis.....	568
On fractional fertilization of muskmelons as a preventive of disease, W. C. Sturgis	568
Notes on some tomato diseases, F. S. Earle.....	569
Observations on tomato blight, C. E. Mead	570
Fruit diseases and how to treat them, L. C. Corbett	573
Dry rot, brown spot, or Baldwin spot of apples, W. T. Macoun.....	570
On the prevention of raspberry anthracnose by cultural methods, W. C. Sturgis	570
White rot of the grape, L. Ravaz.....	571
Stem-rot disease of carnations, W. E. Britton	571

ENTOMOLOGY.

Report of the entomologist, J. Fletcher	574
Report of the entomologist, A. D. Hopkins	580
Insect notes, W. E. Britton	580
Some insects of the year 1899, R. H. Pettit.....	575
How insects are studied at the Ohio Agricultural Experiment Station, F. M. Webster	580
A recent observation on <i>Filaria nocturna</i> in <i>Culex</i> , G. C. Low	575
Note on <i>Collops bipunctatus</i> , T. D. A. Cockerell	580
The clover-root borer (<i>Hylastes obscurus</i>), F. M. Webster.....	576
Combating the gypsy moth (<i>Porthetria dispar</i>), Y. Sjöstedt.....	576
A new method of combating the gypsy moth, Rörig	577
Washes and sprays for combating plant lice, woolly aphis, and similar pests, E. Fleischer	578
Some important insecticides, fungicides, and apparatus for their application, W. G. Johnson, C. O. Townsend, and H. P. Gould.....	581
Some important spraying apparatus and other accessories, H. P. Gould	581
A test of spray nozzles, N. O. Booth	578

FOODS—ANIMAL PRODUCTION.

Preliminary report upon the composition and properties of the fat in "firm" and "soft" pork, F. T. Shutt.....	581
Coffee substitutes, C. D. Woods and L. H. Merrill	586
Inspection and analyses of foods, M. A. Scovell	586
Feeding-stuff inspection, C. D. Woods and J. M. Bartlett	587
Potato pomace, J. M. Bartlett.....	587
Feeding nonsaccharine sorghums, C. E. Mead.....	587
Feeding experiments with steers to test the value of cocoa shells, F. Albert...	582
The value of maize-germ-molasses feed for fattening lambs, F. Albert	583
Experiments with lambs to study the effect of different concentrated feeding stuffs on the character of the tallow, F. Albert	583
Feeding experiments with pigs on the value of sugar and influence of increased protein consumption, F. Albert	583
Report of the poultry manager, A. G. Gilbert.....	585
Feeding chickens for growth, G. M. Gowell.....	585
Breeding for egg production, G. M. Gowell	586

DAIRY FARMING—DAIRYING.

Feeding experiments with palm-nut cake, palm-nut residue, linseed meal, castor-bean meal, and peanut meal for milch cows, E. Ramm, C. Momsen, and T. Schumacher.....	589

EXPERIMENT STATION RECORD.

VOL. XII.

No. 6.

"A scientific bibliography is for facts what a dictionary is for words." This is the estimate of M. E. Duclaux, director of the Pasteur Institute, in his introduction to the *Bibliographia lactaria* of Henri de Rothschild, which has just been issued. This is probably the most complete and systematic bibliography of milk which has ever been prepared. It contains 8,375 titles, arranged by subjects, with the entries in chronological order under each subject; an author index with reference to the papers by number, and a chronological list of inventions of apparatus for handling and treating milk.

The review of literature goes back to the beginning of the sixteenth century, the oldest paper cited bearing the date of publication of 1500. The American work is very fully represented, the references cited indicating a surprising amount of research of American literature and great familiarity with the sources of publication.

The amount of labor involved in the preparation of such a bibliography can scarcely be realized. Dr. de Rothschild has of course had the aid of a corps of assistants, and enjoyed splendid library facilities. His own private library is said to be the most complete in dairy literature to be found anywhere. The value of such a bibliography to the investigator or the writer will be readily appreciated. It makes accessible for all time the principal literature relating to the subject which has been published during four centuries. The value of the undertaking is enhanced by the expressed purpose of the author to issue an annual supplement to this volume, covering the current literature.

The preparation of bibliographies of subjects related to agriculture has received an increasing amount of attention in recent years. This attention is well merited, for perhaps in no other line are the articles more widely scattered. The collection of these papers in a systematic and thorough manner adds very greatly to the facilities of the investigator in agricultural science, and the use of such bibliographies becomes more and more desirable as our research progresses. Appreciating the importance of such bibliographical helps, the National Department of Agriculture has of late issued a number of important contributions. Among these the index to literature relating to animal industry, by G. F. Thompson, is especially noteworthy. This is an index to the bulletins and reports issued by the Department of Agriculture from

its establishment in 1837 to the close of 1898. It contains 676 pages, with some 80,000 entries. It covers a wide range of subjects relating to domestic animals, their care and management, diseases and treatment, together with animal products, such as milk, butter, cheese, eggs, wool, meats, etc. This volume, together with the Handbook of Experiment Station Work, which is in process of revision, will furnish a very complete record of the work done by the Department and the experiment stations along these lines.

Two new abstract or bibliographic journals of interest to station workers have recently made their appearance. The first of these is announced as a bibliography, guide, and index to bacteria, and is entitled the *Scientific Roll and Magazine of Systematic Notes*. The editor is Dr. Alexander Ramsey, of England. The great interest which at present attaches to work in bacteriology in its different lines should make such a journal in English a welcome addition to the current periodical literature.

The other journal referred to is the *Geologisches Centralblatt*, devoted to the publication of reviews of contributions in geology and all related sciences. The abstracts are printed in German, French, or English. The journal will appear semimonthly, and is under the editorial management of Dr. K. Keilhack, of Berlin, who has associated with himself a long list of collaborators representing different countries.

Another new monthly periodical, dating from the beginning of the present year, occupies a quite novel field and indicates the extent to which specialization in periodical literature is being carried. It is devoted to the subject of hail and the protection of crops from it (*La Grêle et la Défense des Récoltes*). Much attention is being given to this in the vine-growing regions of France, Italy, and Austria. It is estimated that the loss from hail during the eight years from 1890 to 1897 amounted in the Department of Rhône alone to over \$9,000,000. Systematic cannonading with a smoky powder has been recommended and quite extensively adopted as a means of dispersing destructive hail storms. This practice was first adopted in Italy, and was introduced into France in 1899. The cannonading stations are established and maintained at private expense. The most systematic organization of stations is at Denicé, near Villefranche, where 52 cannon covering an area of 1,000 hectares (nearly 2,500 acres) are operated.

The new journal is a monthly, and is published in the interest of viticulturists who have taken active measures in the direction of hail protection. The initial number contains, in addition to the plan and purpose of the journal, an account of the Hail Protection Congress held at Padua, Italy, November 25-28, 1900, a reprint of an old article on cannonading to dissipate storms, published in 1760, and a reprint of an article by Gastine and Vermorel which is to be noted later.

CONVENTION OF ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS, 1900.

D. W. MAY,
Office of Experiment Stations.

The seventeenth annual convention of the Association of Official Agricultural Chemists met in the lecture hall of the Columbian University, Washington, D. C., November 16, 17, 1900. Eighty-five members and visitors were in attendance. The meetings were presided over by the president, B. W. Kilgore.

In his address the president of the Association favored a national pure-food law, and suggested phases for the cooperation of the official agricultural chemists. The importance of a national standardizing bureau under government control was also emphasized. Under the subject of fertilizers the results of analyses, especially as printed on bags, the misleading naming of special brands, and the importance of a statement setting forth the materials composing the brands, were questions brought to the careful attention of the Association. The value and the results of individual effort in the development or improvement of methods of analysis were strongly brought out. As an example of this, the president cited the development of the method of estimating potash. Especial attention was called to the examination of human foods, and the importance was urged of placing the subject in subdivisions under experienced members of the Association.

Adjournment was taken to accept an invitation of the National Grange to attend a meeting of that order then in session in the city.

FERTILIZERS.

The work on methods of fertilizer analysis during the past year was confined to testing some of the newer methods not yet adopted by the Association, or some particular points in the official methods. No changes in the present methods were made, although several points were recommended for testing the coming year.

Potash.—The referee, L. S. Munson, being absent, the report on potash was read by the secretary. Samples were sent out for the purpose of testing the application of the method of determining water-soluble potash in fertilizers made up entirely or in part of organic material; also to ascertain whether in mixtures of acid phosphate and potash salts it was possible to obtain the theoretical amount of potash added.

Eleven analysts reported. The results obtained for water-soluble potash were very irregular, showing a variation of 0.47 per cent in a total of less than 2 per cent of potash present. In the case of obtaining the theoretical amount of potash in mixtures of acid phosphates and potash salts the results were more regular, but still showed a wide variation. The average of the results with the mixture gave 6.12 per cent of potash, while the theoretical amount was 6.35 per cent. Work along these lines will be continued.

H. A. Huston suggested that the loss of potash might have been occasioned by continued boiling, as reported by the Kentucky Station several years ago.

Nitrogen.—Owing to the continued bad health of the referee, F. S. Shiver, the report on nitrogen was presented by the associate, W. R. Perkins. The work has been limited to a study of methods for determining availability of organic nitrogen by the neutral permanganate (Street) and pepsin-hydrochloric acid (Jones) methods. While the work of the year has not materially approached the settlement of the question of the value of the two methods, the associate believed that by closely following certain points in manipulation as outlined the permanganate method can be made to give good results. It was suggested that the work on the two methods be continued.

Some of the work on availability of nitrogen carried on at the Rothamstead Experiment Station was discussed by Dr. Bernard Dyer.

A paper by W. A. Withers and G. S. Fraps on the Rate of nitrification of certain fertilizers was presented by the former. The experiments reported showed a very close correspondence between the rate of nitrification during 3 weeks and the availability as shown by chemical and vegetation tests, except in the case of sulphate of ammonia. The latter seemed to be nitrified much more slowly than the organic compounds, yet in many of the field experiments it gave results closely approximating those given by nitrate of soda. The nitrification of all materials tested, except bone, was facilitated by adding calcium carbonate. This investigation will be continued.

C. B. Williams presented a report on Variable ammonia results in mixed fertilizers. In tests of methods of analysis on fertilizers containing fish scrap, blood, tankage, or nitrate of soda, results showed that where the samples were put through a 1.25 mm. sieve (No. 20) the differences ranged from 0.27 to 1.96 per cent. When put through sieves of 0.625 mm. (No. 40) the differences ranged from only 0.02 to 0.14 per cent. In all these determinations the modified Kjeldahl method was used with 0.7 gm. of substance. It is hoped to supplement these results by further work during the coming season.

After some discussion on the added value of a fertilizer having its nitrogen in the form of nitrates, a motion was adopted expressing the

desirability of determining and reporting upon the forms of nitrogen in the analysis of commercial fertilizers.

The Jones and Street methods for nitrogen were recommended for further trial at the hands of the referee for next season.

Phosphoric acid.—The report was presented by the referee, E. G. Runyan. Results were reported from 19 analysts on the samples sent out for determination of the total phosphoric acid by the official gravimetric method, optional volumetric method, and volumetric by shaking at room temperature. In 16 reports the several methods agreed fairly well, and may be considered quite satisfactory.

Results on the determination of iron and alumina in phosphates were reported by 7 analysts. These were rather discordant, although agreeing more closely than the previous year. While the results reported on the determination of iron by the permanganate method do not agree very well, the referee believes this to be the best means for determining iron in phosphates. The results of tests of the acetate and the phenylhydrazin methods of alumina determination do not warrant the drawing of definite conclusions, but the referee believes that some form of the acetate method will prove to be the better.

H. J. Wheeler presented a paper upon Increased accuracy in phosphoric acid determination. In this he asked the special attention of the Association to the work of Gooch and Austin (E. S. R., 11, p. 107), and suggested certain modifications of the official method of determining phosphoric acid. By the proposed modification close approximations to theoretical results are obtained, and the laboratory is freed from the strong odor of ammonia and the expense materially reduced.

P. MacFarland read a paper on basic slag, in which he reviewed the sale of this material in Canada and the trials of the official chemists in the Dominion in establishing a proper valuation of the soluble phosphate content. He presented the results of certain modifications in the methods of analysis of this product, and asked the cooperation of the Association in the further study of the question. After some discussion the question of the adoption provisionally of the 2 per cent citric acid solution method of Wagner and the consideration of the paper presented was referred to the referee for another year.

C. B. Williams described Kilgore's modification of the volumetric method of estimating phosphoric acid. By this method 30 phosphoric acid samples may be analyzed with ease daily. From a large number of comparative tests with the gravimetric method the results were in all cases reported as extremely satisfactory.

SOILS.

The report on soils by the referee, B. L. Hartwell, covered the past 2 years. At the meeting in 1898 the Association recommended work upon the so-called international method of determining assimilable

potash by using dilute nitric acid as a solvent, a further trial of Hollemann's method for the determination of the active lime compounds by using water saturated with carbonic acid, and further tests with alkaline ammonium chlorid as a solvent for potash. The results of the work covering the period indicated were presented. The data, so far as obtained, do not justify drawing any definite conclusions and the work will be continued.

The referee also read a paper on A pot experiment to test field observations concerning soil deficiencies. Attention was called to the fact that often after a lapse of time a second analysis of a given soil failed to account for elements added in fertilizers or for amounts removed by crops. This difficulty was believed to be probably due to failure of the soil sample to properly represent the area from which it was taken. It was suggested that soils intended for field experiments should have applied to them other lacking ingredients than the one to be tested, and that soils intended for testing methods for determining assimilable plant food should be subjected to pot experimentation before being distributed by the referee.

After some discussion a recommendation was adopted instructing the referee on soils to consider methods for the mechanical analysis of soils and the statement of the results, and also to consider the method of soil sampling suggested by Dr. Dyer.

The following provisions were also adopted as official: The use of fifth-normal nitric acid as well as hydrochloric acid of the same strength in determining phosphoric acid; the employment of a 3 mm. sieve where 100 gm. or more of a sample is used for the determination; and the statement in the report of soil examination of such additional data as to enable calculating the total amount of the several ingredients in a given area of soil to the depth at which it was sampled.

LIQUOR AND FOOD ADULTERATION.

The report on liquor and food adulteration was presented by William Frear. No recommendations were made. A list of definitions adopted tentatively for certain classes of products was presented, and a collection of data of analyses of foods, condiments, and liquors. A resolution was adopted by the association placing the subject of liquor and food adulteration under fifteen heads, as follows: (1) meat and fish, (2) fats and oils, (3) cereal products, (4) infant and invalid foods, (5) saccharine products, (6) canned vegetables, (7) tea, coffee, cocoa, etc., (8) spices and condiments, (9) vinegar, (10) flavoring extracts, (11) fruit products, (12) fermented and distilled liquors, (13) baking powder and baking chemicals, (14) preservatives, and (15) coloring matters. The referee was authorized to associate with himself other members of the Association to investigate the several subjects and prepare reports.

ASH ANALYSIS.

The referee, A. E. Shuttleworth, outlined the work on ash and the method of procedure. Results were reported from 3 analysts. The writer stated that the place to begin the improvement of the method of analyses is in the preparation of the ash. Volatilization and fusion are two noteworthy sources of error. The use of calcium acetate solution overcomes the difficulty of fusion, and a closed platinum apparatus prevents volatilization. These were adopted by the Association as official. A paper by G. S. Fraps was submitted on the Loss of sulphur in preparing ash of plants. Two methods were tested. Ten grams of substance were burned alone at as low temperature as possible, and 10 gm. were burned after the addition of a solution of calcium acetate. In no case was all the sulphur of the plant contained in the ash, and the loss with the calcium acetate was from 6 to 100 per cent more than when the substance was burned alone.

FOODS AND FEEDING STUFFS.

The report was presented by W. H. Krug and covered the results for 2 years. Three samples consisting of wheat, bran, and peas were sent out. From the results obtained, three suggestions were made by the referee: (1) That the present methods for moisture be further studied with the view of fixing the time required and the exact temperature at which the determination must be made; (2) the further study of the effect of various methods of distillation on the results obtained by the phloroglucin method; and (3) the determination of the effect of the length of time which the precipitated distillate stands upon the amount of phloroglucin obtained.

G. S. Fraps presented Notes on the determination of pentosans and crude fiber. Attention was called to probable sources of error in the official method of distillation in determining pentosans, in the quality of phloroglucin used, and in the composition of the products obtained by distillation of pentosans with hydrochloric acid. A method devised by König was proposed for preparing crude fiber practically free from pentosans (E. S. R., 10, p. 411). A method of purifying phloroglucin was adopted; also several changes in manipulation in the provisional method for the determination of pentosans by means of phloroglucin.

DAIRY PRODUCTS.

In his report the referee on dairy products, J. B. Weems, outlined the work of the past year, which was the investigation of the official and provisional methods and their modifications in determining casein and albumen in milk. The results of the different analysts were presented and certain changes in the methods recommended. The Frear alum method was substituted for the magnesium sulphate method for determining the casein in milk.

E. E. Ewell presented a method for the determination of the specific gravity of fats. The question of making determinations at 100° C. instead of at the temperature of boiling water was referred to the referee for next year.

TANNIN.

The report on tannin was presented by O. Carr. W. H. Krug read a paper on Comparative hide-powder tests. He suggested that in addition to the present requirements a clause be inserted to the effect that the hide powder used in the determination of the nontannins shall be neutral.

A paper by H. W. Wiley and W. H. Krug reported results of a Comparison of the international filter-tube method and the official hide-powder method. The results show that the filter-tube method gives lower nontannins and correspondingly higher tannins than the official method. Attention was called to the necessity, in the interest of commerce, of a uniform international method.

The use of the centrifugal and the pasteur filter in the estimation of tannin was adopted.

FUNGICIDES AND INSECTICIDES.

The report of the associate referee, L. A. Voorhees, consisted largely of a further compilation of methods. The methods of 13 analysts were given in full, and they were adopted provisionally for trial and comparison in actual analytical work.

No report on sugar analysis was rendered by the referee on that subject. The referee for next year was instructed to investigate and report upon the relative value of the present official method and the German method for the optical determination of sucrose by inversion.

H. W. Wiley presented a report of the meeting of the International Congress of Chemists.

The secretary was requested to insert in the next edition of the methods of analysis the latest revision of the table of atomic weights reported by the committee of the American Chemical Society.

The report of the abstract committee was made by W. H. Beal.

Resolutions were adopted indorsing the movement toward the establishment of a national standardizing bureau.

OFFICERS OF THE ASSOCIATION.

The officers elected for the ensuing year are as follows: President, L. L. Van Slyke, Geneva, N. Y.; vice-president, H. J. Wheeler, Kingston, R. I.; secretary, H. W. Wiley, Washington, D. C.; additional members of executive committee, W. R. Perkins, Agricultural College, Miss., and F. W. Traphagen, Bozeman, Mont.

The referees as announced are as follows:

Phosphoric acid: Referee, H. K. Miller, Lake City, Fla.; associate referee, C. H. Jones, Burlington, Vt.

Nitrogen: Referee, W. R. Perkins, Agricultural College, Miss.; associate referee, F. W. Morse, Durham, N. H.

Potash: Referee, C. L. Hare, Auburn, Ala.; associate referee, L. S. Munson, Washington, D. C.

Soils: Referee, M. E. Jaffa, Berkeley, Cal.; associate referee, F. P. Veitch, Washington, D. C.

Ash: Referee, G. S. Fraps, Raleigh, N. C.; associate referee, E. W. Magruder, Richmond, Va.

Dairy products: Referee, J. A. LeClerc, Geneva, N. Y.; associate referee, G. W. Cavanaugh, Ithaca, N. Y.

Foods and feeding stuffs: Referee, W. H. Krug, Washington, D. C.; associate referee, C. A. Browne, jr., State College, Pa.

Liquors and food adulteration: Referee, W. D. Bigelow, Washington, D. C. (meat and fish, fermented and distilled liquors); associate referees, A. McGill, Ottawa, Canada (cereal products); P. T. Aschmann, Pittsburgh, Pa. (infant and invalid foods—carbohydrate); L. M. Tolman and L. S. Munson, Washington, D. C. (fats and oils, fruit preparations, coloring matters, canned vegetables); A. E. Leach, Boston, Mass. (confections and saccharine products); A. L. Winton, New Haven, Conn. (spices and condiments, baking powders, and baking-powder chemicals); W. Frear, State College, Pa. (vinegar); A. S. Mitchell, Milwaukee, Wis. (flavoring extracts); W. M. Allen, Raleigh, N. C. (preservatives).

Sugar: Referee, E. E. Ewell, Washington, D. C.; associate referee, G. L. Spencer, Washington, D. C.

Tannin: Referee, W. K. Alsop, New York, N. Y.; associate referee, W. H. Teas, Ridgway, Pa.

Fungicides and insecticides: Referee, L. A. Voorhees, New Brunswick, N. J.; associate referee, J. K. Haywood, Washington, D. C.

The committees will remain the same as last year (E. S. R., 11, p. 210).

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Comparative methods of determining nitrogen in nitrates, L. VON WISSELL (*Jour. Landw.*, 48 (1900), No. 2, pp. 105-115, fig. 1).—Comparative tests of the following methods are reported: (1) The Möckern method¹ (reduction in alkaline solution with zinc and iron powder), (2) the Ulsch method,² (3) the Devarda method (reduction in alkaline alcoholic solution with ammonium-copper-zinc alloy—E. S. R., 4, p. 676), and (4) Förster's modification of the Kjeldahl method, using sulphuric acid containing salicylic acid. The Devarda method gave in all respects the most satisfactory results. Of the other three methods the Ulsch and the Förster methods gave equally good results, while the results by the Möckern method were too low. The author considers the Devarda method the quickest and most convenient of the methods tested.

The determination of perchlorates in potassium and sodium nitrates, N. BLATTNER and J. BRASSEUR (*Chem. Ztg.*, 24 (1900), No. 72, p. 767; *abs. in Chem. Centbl.*, 1900, II, No. 14, pp. 780, 781).—The authors' method (E. S. R., 10, p. 410) is modified as follows: Heat 5 gm. of the dried and finely powdered nitrate with 7 to 8 gm. of pure calcium hydrate (5 gm. of water and 100 gm. of caustic lime) in a platinum or porcelain crucible for 15 minutes over a Bunsen flame, cool and wash into a 125 cc. flask, and allow to stand for 1 hour for the complete diffusion of the soluble salts. Fill to the mark, allowing 3 cc. for the volume of the undissolved lime, shake and filter, neutralize 100 cc. of the filtered solution with dilute nitric acid, using methyl orange as an indicator, and titrate according to Mohr with potassium chromate and decinormal silver solution.

Method of determining chlorid, chlorate, and perchlorate in the presence of each other, N. BLATTNER and J. BRASSEUR (*Chem. Ztg.*, 24 (1900), p. 793; *abs. in Chem. Centbl.*, 1900, II, No. 15, p. 820).—The method is as follows: Dissolve 20 to 40 gm. substance in 200 cc. of water. Determine chlorine in 50 cc. of this solution by titration with decinormal silver solution. Conduct sulphurous acid through another 50 cc. of the solution or add 50 cc. of a saturated solution of

¹ Landw. Vers. Stat., 1892, p. 165.

² Ztschr. Analyt. Chem., 1891, p. 175.

sulphurous acid and boil gently to drive off excess of SO_2 . This treatment reduces the chlorate to chlorid. Neutralize with pure calcium carbonate and titrate for chlorin. The perchlorate is determined by the method described above.

Experiments in the determination of cell-wall material, hemicelluloses, and cellulose in plants, A. KLEIBER (*Landw. Vers. Stat.*, 54 (1900), No. 3-4, pp. 161-213).—The author reports a comparative study of the Henneberg (Weende), Lange (E. S. R., 8, p. 741), Hoffmeister (E. S. R., 10, p. 606), and Schulze (E. S. R., 8, p. 741) methods of determining crude fiber, on a variety of coarse fodders, palm cake, etc. Concordant results could not be obtained by the Lange method, duplicates differing by as much as 60 per cent. The author agrees with Suringar and Tollens (E. S. R., 8, p. 742) that the cellulose is attacked to a considerable degree in this method. Both the Hoffmeister and Schulze methods, which are similar in that potassium chlorate is employed, gave crude fiber containing too much protein. The results by the Schulze method were, however, more concordant than by the Hoffmeister method. The author modified these 2 methods by boiling for 2 hours with 1.25 per cent sulphuric acid, obtaining materially lower results, indicating that the crude fiber as determined by the original methods contains considerable quantities of material easily soluble in dilute acids (hemicelluloses). The results with this modification were almost invariably concordant. The author believes that if the Hoffmeister or Schulze methods are to be used at all they should be used with the modification proposed, although he does not claim that the method is free from objection, as the cellulose obtained may not be true cellulose and may contain oxycellulose.

An attempt was made to determine the total amount of cell-wall constituents in plants by treating 3 gm. of air-dry substance with 200 cc. of 0.15 per cent potash solution for 2 to 3 days, collecting on a dried and weighed filter, washing with cold and warm water, with cold and hot alcohol, and finally with ether, and then drying to constant weight. The ash and protein were determined and deducted. This method and the use of alkali solution made by dissolving 5 gm. of potassium hydrate in 1 liter of water gave practically the same results. The end product by both methods contained quite large amounts of protein. In the case of substances rich in starch the material was treated with malt extract. The results of these determinations as given by the author are not considered altogether reliable, being possibly too high in some cases and in others too low. The results were considerably higher than those for crude fiber in the same materials.

Experiments were also made in the determination of hemicelluloses by treating the cell-wall material, as obtained above, with 1.25 per cent sulphuric acid, but the question as to how long the treatment

should be continued, the difference in time required by different materials, and other details prevented obtaining reliable results. In all cases the treatment with 1.25 per cent sulphuric acid dissolved considerable amounts of the nitrogen-free cell-wall constituents.

The relation of the reducing power of normal urines to the amount of certain nitrogen compounds present, J. H. LONG (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 6, pp. 309-327). The nature of the reducing bodies, behavior of uric acid with copper solutions, the determination of creatinin, uric acid, urea and ammonia, and the ratio of urea to uric acid are discussed on the basis of the investigations reported. While it is not considered possible to draw any exact generalizations regarding the relation between the character of the food and the results obtained, "the urines showing the highest reduction ratio for uric acid and creatinin, as compared with the total reduction, were from men with the strongest physique with a diet containing much meat. On the other hand, the lowest uric acid and creatinin reductions correspond to cases of slighter physique and lower nutrition. . . . But from most of the urines no characteristic relation is apparent."

The nucleic acid of the embryo of wheat and its protein compounds, T. B. OSBORNE and G. F. CAMPBELL (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 305-339; *Jour. Amer. Chem. Soc.*, 22 (1900), No. 7, pp. 379-413). The authors used for their investigations a quantity of wheat germ meal from which the bran and endosperm had been very thoroughly removed. By methods which they describe in detail they found that the embryo of the wheat kernel contains the following substances:

(1) A nucleic acid, in considerable quantity, which is not identical with any nucleic acid heretofore described.

"This acid is insoluble in water, forms soluble as well as insoluble compounds with proteid substances, and on hydrolysis yields guanin, adenin, phosphoric acid, and other products not yet identified."

(2) Leucosin and an albumin (constituting about 10 per cent of the embryo), formerly found by the writers in small quantities in the whole kernel of wheat, rye, and barley, and abundantly in malt.

"By saturating extracts of the kernel or of the embryo with sodium chlorid, the leucosin is largely precipitated, from the former as a substance readily soluble again in water, from the latter as an insoluble compound containing about 30 per cent of nucleic acid. From the latter precipitate, dilute salt solution extracts a small amount of nearly phosphorus-free proteid, which behaves like a globulin, being precipitated by dilution or by dialysis, but having essentially the same ultimate composition as leucosin. By dialyzing the aqueous extract in water, nearly all the leucosin contained in it is precipitated, not like a globulin, but as an insoluble compound containing about 20 per cent of nucleic acid."

(3) A globulin, precipitated in spheroids by dialysis and by dilution as a coherent deposit. The yield was about 5 per cent of the embryo.

"Our preparations of this globulin contained from 6 to 17 per cent of nucleic acid, most of them from 12 to 15 per cent. From this the proteid could not be separated by fractional precipitation. . . .

"In composition and properties this globulin agrees with that found by the writer in the kernels of wheat, rye, and barley. So far as we have been able to observe, it differs from edestin, the crystalline globulin obtained from seeds of hemp, flax, and squash only in containing two-thirds as much sulphur."

(4) Two proteoses, together constituting about 5 per cent of the embryo.

"About one-third of the total nitrogen of the embryo is not extracted by water and salt solutions and appears to belong to insoluble compounds. This nitrogen is accompanied by phosphorus corresponding to about 6.75 percent of nucleic acid, which would contain two-thirds of this insoluble nitrogen. It seems probable, therefore, that this insoluble nitrogen belongs largely to insoluble compounds of nucleic acid and protein. . . .

"The proteids of the embryo differ from those of the dormant endosperm, of this as well as of other seeds, in the facility with which they undergo changes. These changes are the result of a redistribution of acids among the protein and other basic molecules, so that compounds form in the extracts of the embryo which contain various proportions of nucleic acid according to the changing conditions.

"The writer has shown that the globulin, edestin, forms crystalline compounds with one and with two molecules of acid and also compounds with a greater number of acid molecules. There is reason to believe that all other native protein substances form similar compounds; in other words, that proteins are distinctly polyacid bases and that the acid characters which proteids display are due to acids united to their protein molecules, probably in the same manner as in the salts of the purin bases.

"These nucleic acid compounds of the protein constituents of the wheat embryo appear to be compounds of this order. According to this view, no special distinction can be made between nucleins and nucleoproteids, the former being simply compounds containing a greater number of molecules of nucleic acid united to one molecule of protein.

"That the wheat embryo in fact contained the same nucleic acid compounds as we have obtained from the extracts is highly improbable. All that we can conclude is that the embryo contains the different protein substances described, together with nucleic acid, and that these may unite to form a number of different compounds according to the conditions which prevail at any given time."

The proteids of the egg yolk, T. B. OSBORNE and G. F. CAMPBELL (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 339-348; Jour. Amer. Chem. Soc., 22 (1900), No. 7, pp. 413-422*).—The authors found that sodium chlorid solutions dissolve from egg yolk a large amount of protein matter resembling a globulin, but which is believed to be a mixture of compounds of protein matter with lecithin.

"Preparations of these compounds contain from 15 to 30 per cent of lecithin. The more soluble products obtained by fractional precipitation contain larger proportions of lecithin than the less soluble—that is, they are more acid compounds. These compounds might well be called lecithin-nucleo-vitellin.

"The lecithin thus combined is not removed by ether, but readily by alcohol. The insoluble lecithin-free proteid, obtained by treating the lecithin compounds with alcohol, has a constant composition when obtained from successive fractional precipitations of the lecithin compound. . . .

"This substance on digesting with pepsin yields paranuclein of variable composition. When the analyses of the nucleovitellin and the paranuclein are calculated

free from phosphoric acid H_3PO_4 , possibly identical with 'paranucleic acid,' the composition found for the organic part of all of these preparations is so nearly the same as to show that the proteid and the nuclein are both compounds of one and the same proteid body, vitellin, with a phosphoric acid, possibly H_3PO_4 , $H_8P_2O_9$, or some very simple organo-phosphoric acid."

The protein constituents of egg white, T. B. OSBORNE and G. F. CAMPBELL (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 348-375; Jour. Amer. Chem. Soc., 22 (1900), No. 7, pp. 422-450*).—In a previous paper (E. S. R., 11, p. 309) the author stated that with the substance commonly called ovalbumin there is associated one or more other proteid bodies, the properties of which were not definitely ascertained. The present investigation, which was on a larger scale, confirms this conclusion and presents much additional information respecting these other proteid bodies.

In addition to ovalbumin the authors find in egg white ovomucin, conalbumin, and ovomucoid. The properties and composition of each of these bodies are described at length. Ovalbumin is the chief constituent of egg white, constituting over 50 per cent. Ovomucin is a glycoproteid and constitutes about 7 per cent of the proteid matter of egg white. Conalbumin is obtained from the fractions from which the proteids of egg white are obtained after separating the crystalized fractions. It is separated by heating to 65° and is designated conalbumin "on account of its close relation in properties and composition to ovalbumin. What this relation may be, we have not determined. Conalbumin and ovalbumin may be different compounds of the same protein, or the former may be a derivative of the latter involving a molecular change." Ovomucoid, a glycoproteid, is obtained after all the proteids coagulable by heat have been separated, being precipitated by ammonium sulphate solution. The composition of these proteids is shown in the following table:

Composition of ovomucin, ovalbumin, conalbumin, and ovomucoid.

	Carbon.	Hydrogen.	Nitrogen.	Sulphur.	Phosphorus.	Oxygen.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Ovomucin	50.69	6.71	14.49	2.28	25.83
Do	50.95	6.85	14.82	1.94	25.44
Ovalbumin (average of 6 preparations) ..	52.75	7.10	15.51	1.62	0.122	22.898
Conalbumin (average of 3 preparations) ..	52.25	6.99	16.11	1.70	22.95
Ovomucoid	49.02	6.45	12.71	2.38	29.44
Do	48.90	6.61	12.16	2.34	29.99

The purest preparations of ovalbumin, having a constant specific rotation and the same composition and temperature of coagulation, all gave solutions when boiled with acids which yielded considerable quantities of crystalline precipitates with phenylhydrazin. The amount of os ozone actually obtained corresponds to from 2 to 2.5 per cent of carbohydrate calculated as glucose. The authors discuss the

origin of this carbohydrate material, concluding that it "does not originate in admixed ovomucoid, but is derived from the substance constituting the crystallized ovalbumin."

"We have stated our belief that crystallized ovalbumin is a compound of some acid with protein substance and consider it quite probable that this acid contains the carbohydrate group.

"We have been unable to obtain any evidence of carbohydrate in edestin, the crystallized globulin of hemp seed, nor, according to Hammarsten, can a carbohydrate be split from casein, vitellin, myosin, and fibrinogen. This subject requires further careful study before a definite conclusion can be reached. At present the preponderance of evidence indicates that the carbohydrate is not derived from the protein molecule, but from substances combined with the protein as it is obtained from the tissues or secretions."

On the chemical properties of the fat in Norwegian creamery butter, F. H. WERENSKIOLD (*Aarsber. Offent. Foranst. Landbr. Fremme*, 1899, pp. 117-127).—Samples of butter churned in 9 Norwegian creameries were taken at regular intervals by authorized agents under conditions that precluded chances for adulteration, 254 samples being taken during 1899. The following data show the extremes obtained during the year:

Specific gravity (at boiling point of water).....	0. 8636- 0. 8678
Specific gravity (at 100° F.) 9082- . 9130
Refractive index (at 45° C.)	39. 0 -43. 7
Volatile acids (Reichert-Wollny number)	21. 2 -34. 7

The variations obtained are believed to be too narrow for Norwegian butter. The author finds that poor nutrition, exposure to cold, and differences in the system of feeding practiced in summer and in winter are the chief causes of the variations in composition. A higher specific gravity and content of volatile acids and a lower refractive index were obtained in winter than in summer in the case of all creameries. As a general rule cold weather occurring when the cows were on pasture depressed the specific gravity and the Reichert number and increased the refractive index.—F. W. WOLL.

A systematic handbook of volumetric analysis, F. SUTTON (*London: J. & A. Churchill, 1900, pp. XI+640, figs. 116*).—The eighth edition of this well-known treatise, revised and enlarged. "A considerable number of additions and alterations have been made to methods given in former editions, and several substances not previously treated have been introduced."

The determination of nitrogen in nitrate of soda, O. BÖTTCHER (*Jour. Landw.*, 48 (1900), No. 3, pp. 287-289).—A reply to a criticism by L. von Wissell (see p. 510) of the method proposed by the author (the so-called Möckern method).

A reply to the above remarks, L. VON WISSELL (*Jour. Landw.*, 48 (1900), No. 3, pp. 291, 292).

Note on the determination of nitric nitrogen by Schloesing's method, C. DAVIDSON (*Chem. News*, 81 (1900), No. 2101, pp. 97, 98, fig. 1).

A modification of Péligot's absorption apparatus for ammonia determinations, F. PANNERTZ (*Ztschr. Analyt. Chem.*, 39 (1900), No. 5, pp. 318-320, fig. 1).—The lower U-tube of the Péligot apparatus is so arranged as to prevent regurgitation of the liquid in the absorption bulb.—C. B. WILLIAMS.

Preparation of sodium cobaltinitrite and its application for the detection of potassium, E. BEILMANN (*Ztschr. Analyt. Chem.*, 39 (1900), No. 5, pp. 284-289).—The author claims that this reagent is more sensitive than platinum chlorid and far less expensive.—C. B. WILLIAMS.

The estimation of formic acid in the presence of acetic acid, F. SPARRE (*Ztschr. Analyt. Chem.*, 39 (1900), No. 2, pp. 105, 106).—The author strongly recommends the method of Portes and Ruyssen, but thinks they intended to instruct the employment of a 1 per cent solution of the substance instead of a 10 per cent, as the amount of mercuric chlorid indicated to be used is not sufficient for a 10 per cent solution.—C. B. WILLIAMS.

Refractometric butter analysis, A. PARTHEIL and J. VON VELSEN (*Arch. Pharm.*, 238 (1900), pp. 261-279; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 455, II, p. 633).

On the determination of the iodine value, J. J. A. WILS (*Analyst*, 25 (1900), Feb., pp. 31-35).

Detection of cane sugar in milk sugar, J. LANDIN (*Chem. Ztg.*, 24 (1900), No. 21, p. 211).

Methods of sugar analysis of the laboratories of the French Ministry of Finance, E. MASCART (*Ztschr. Ver. Deut. Zuckerind.*, 1900, No. 537, II, pp. 937-939).

The quantitative determination of volatile oils in spices, K. MANN (*Chem. Ztg.*, 24 (1900), No. 13, p. 124).

Determination of tannins, L. SPECIT and F. LORENZ (*Chem. Ztg.*, 24 (1900), No. 17, pp. 170, 171, fig. 1).

Nut oils, L. H. MERRILL (*Maine Sta. Bul.* 65, pp. 108-111).—The author reports determinations of the refractive index, specific gravity, iodine absorption number, and the calories per gram of oils of the following nuts: Beechnut, Brazil nut, butter-nut, filbert, hickory, pecan, pistachio, pine nut, walnut, peanut (raw and roasted), and cocoanut. The method of analysis is given and the properties of nut oils are briefly discussed.

Limestones, petroleum, etc., A. M. PETER and H. E. CURTIS (*Kentucky Sta. Rpt.* 1898, pp. XXII, XXIII).—Analyses of 6 samples of limestone, 2 of petroleum, and 1 of an unidentified mineral are reported.

The wide occurrence of indicators in nature, G. S. FRAPS (*Amer. Chem. Jour.*, 24, (1900), No. 3, pp. 271-276).—"Some 74 kinds of colored flowers, both wild and cultivated, the leaves of 5 varieties of coleus, the cowpea bean, the blackberry, mulberry, smilax berry, strawberry, and the red beet were extracted with water or dilute alcohol and the extract tested for indicators." The results show that nearly all of the extracts possessed indicator properties, and some were quite sensitive. The materials are grouped in 4 classes as regards their behavior with acids and alkalis.

A burette for accurate gas analysis, A. H. WHITE (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 6, pp. 343-349, figs. 5).

A convenient micro-polariscope for food examination, A. L. WINTON (*Reprinted from Jour. Appl. Micros.*, 2 (1899), No. 10, pp. 550, 551, figs. 2).—This instrument and its use are briefly described.

A simple thermoregulator, F. BOLM (*Ztschr. Analyt. Chem.*, 39 (1900), No. 5, pp. 315-317, figs. 2).—The efficiency of the regulator depends very much upon the construction of the bath. Asbestos-lined, water, or oil baths are recommended by the author.—C. B. WILLIAMS.

BOTANY.

A study of the root systems of cultivated plants grown as farm crops, A. M. TEN Eyck (*North Dakota Sta. Bul.* 43, pp. 535-550, figs. 12).—In a previous publication (*E. S. R.*, 11, p. 215) a prelimi-

nary report is given on the root systems of wheat, oats, and corn, with some discussion of the root systems of other crops. The present bulletin is devoted to investigations in the same line conducted in 1899, and includes a brief review of the study of the roots of wheat, oats, and corn, and of the manner in which the root samples were prepared.

A further investigation of the root system of flax showed that flax possesses a very intricate system of rooting, and while the roots are not as long, they more completely occupy the upper layers of the soil than the roots of wheat or oats. The roots of field peas were investigated on plants 86 days after planting. The vines at this time were $5\frac{1}{2}$ ft. long, while the roots reached only to a depth of 3 ft. and were rather sparingly supplied with branches and fibers. Like the roots of the flax, the bulk of the fibrous roots lie within 8 or 10 in. of the surface, showing that in practice peas do not require a deep soil.

The roots of 1 and 2 year-old plants of *Bromus inermis* were examined. At 1 year old the roots had attained a depth of over 4 ft. and formed a good sod. The roots of the 2-year-old grass were traced to a depth of $5\frac{1}{2}$ ft., and the author believes they probably went a foot deeper. Comparisons were drawn between the root systems of native prairie grasses, timothy roots, and the roots of *Bromus inermis*, showing that the native prairie grasses do not make as heavy a sod as the cultivated ones, the prairie-grass roots in the sample examined reaching less than 3 ft. in depth.

In the previous investigation the specimens of potato roots were considered unreliable on account of the plants having been injured by frost. In the investigations here reported, samples were taken of an early and a late variety of potatoes, from which it was seen that the main portion of the root growth is superficial. Forty-three days after planting, the principal part of the root development was found to lie within 8 in. of the surface of the ground. The lateral roots had extended from hill to hill and interlaced. Some of the principal lateral roots were found to be only $2\frac{1}{4}$ in. from the surface at 6 in. from the hill. This root development would indicate the necessity of shallow cultivation of this crop, and this was confirmed in experiments with deep and shallow cultivation, the results showing a decided advantage for the shallow cultivation of potatoes unhilled. The samples of a late variety of potatoes showed that late potatoes root more freely and more deeply than early ones, and as a result will not stand as close planting as the early varieties. When the hills are about 3 ft. apart each way, the soil is very fully occupied by the roots to a depth of 3 ft.

From examination of the roots of sugar beets it was found that this crop does not develop lateral roots near the surface of the ground. The greatest amount of branching and fibrous growth of beet roots takes place in the space between 8 and 14 in. in depth.

The effect of subsoiling on root growth and development of sugar

beets was investigated, with the result that on the subsoiled plats there was a considerably better development of feeding roots, and the main root was more symmetrically developed.

The soils in which the various roots grew are described at some length, and general remarks and conclusions similar to those in the previous bulletins are given.

Sugar-producing plants, L. GESCHWIND (*Ann. Agron.*, 26 (1900), No. 8, pp. 383-409).—The author has given a brief report on the present state of information relative to sugar producing plants, dividing them into the following categories: (1) Those which have been shown experimentally to contain sugar, but whose utilization in an industrial manner has not been attempted; (2) those plants used in producing sugar, but which are more or less local in their use; and (3) those which furnish the greater portion of the sugar of commerce. In the first category are mentioned carrots, melons, cucumbers, gourds, agaves, etc. In the second class are described various species of palms, maize, sorghum, and sugar maple, while in the third are described sugar cane and sugar beets.

Hydrocyanic acid in plants, M. SOAVE (*Nuov. Giorn. Bot. Ital.*, 6 (1899), pp. 219-238; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 3, p. 343).—From a series of experiments upon the bitter almond and *Pangium edule* it is concluded that cyanogen compounds in plants are transitional substances from which are obtained nitrogenous food materials by the plants. From the time the seeds begin to swell, so long as the embryo is dormant, the bitter almond contains no trace of hydrocyanic acid. It makes its appearance only when the seed begins to germinate and then only in the stem, none being observed either in the root or the cotyledons. Sweet almonds are said to contain no trace of amygdalin.

Soil inoculation for promoting the growth of legumes, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 150, 151, pl. 1).—A report is given of the use of Nitragin, in which a second year's growth of clover which had been inoculated is compared with similar plats without treatment. While in the first year's crop the difference was slight, the second year's growth on the inoculated plats was more than 3 times that of the untreated. The author states that the results of his 3 years' investigations indicate the possibility of obtaining a good crop of clover on very poor soil with the aid of Nitragin, provided the soil is drained, the season favorable, and there is present a sufficient supply of mineral plant food. Certain difficulties to the introduction of Nitragin are mentioned, among them the difficulty of obtaining the cultures and the necessity of protecting from strong light and keeping at a low temperature. It is suggested that it is possible to obtain the same results by taking soil from fields that have grown good crops of clover and sowing over poor soil.

Twigs of common trees and shrubs, F. H. HILLMAN (*Nevada Sta. Bul.* 45, pp. 16, figs. 18).—This bulletin is the first of a proposed series of studies in plant life, and describes the twigs and buds of poplars, elms, maples, and willows.

Notes on some *Andropogons* in Jamaica, W. HARRIS (*Bul. Bot. Dept. Jamaica*, n. ser., 7 (1900), No. 10, pp. 152-154).—Notes are given on some of the economic uses of *Andropogon squarrosus*, *A. schenanthus*, and *A. nardus*.

Influence of copper salts on plants, E. CHUARD and F. PORCHET (*Bul. Soc. Vaud. Sci. Nat.*, 4. ser., 36 (1900), No. 135, pp. 71-77).—Experiments made by the authors tend to show that the favorable effects of compounds of copper on the growth and fertility of plants have been exaggerated. The increase in the amount of sugar in the fruit of grapes and gooseberries sprayed with Bordeaux mixture is said not to exceed 1 or 2 per cent. Copper was not found present in the leaves. The deeper color of the leaves, they claim, is not due to an increase in the amount of chlorophyll.

The effect of carbon dioxid upon water transportation in plants, P. KOSAROFF (*Bot. Centbl.*, 83 (1900), No. 5, pp. 138-144).—A series of experiments is reported with water cultures of *Phaseolus vulgaris*, leafless stem of *Eupatorium*, leaf of *Acer*, and twigs of *Sparmania*, *Morus alba*, and *Prunus cerasus*, in which the effect of carbon dioxid on water transportation was shown. Carbon dioxid solutions greatly check the ability of plants placed in the solution to take up water. This was found to be true for herbaceous and woody plants. It proved injurious to all living tissues with which it came in contact. The wilting of plants subjected to a continued exposure to carbon dioxid is attributed to the reduction of transpiration.

The electrical effects of light upon green leaves, A. D. WALLER (*Science*, n. ser., 12 (1900), No. 297, pp. 377, 378).—A brief abstract is given of the paper in which appears the result of the author's investigation upon the action of light upon green leaves, being accompanied by electrical effects. Young leaves were placed upon a glass plate and connected with a galvanometer, one portion being shaded and the other exposed to the light. The deflection of the galvanometer during the illumination was sufficient to indicate an electric current in the leaf from the excited to the protected part. The amount of current in some cases was measured, and the effect of various gases, as shown upon the electric current, is given.

The influence of temperature on protein metabolism, D. PRIANISHNIKOV (*Ber. Deut. Bot. Gesell.*, 18 (1900), No. 6, pp. 285-291).—Experiments with pea seedlings showed that the energy of protein metabolism increases with the increase in temperature up to at least 37° C.

Formation of resin in plants, A. TSCHIRCH (*Festsch. Schwendener, Berlin, 1899*, pp. 464-470; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 2, p. 214).—The mode of formation of oil cells in *Cinnamomum cassia* is described in detail. They are said to be developed from small cells filled with protoplasm by the gradual suberation of the cell walls, accompanied by the formation of a layer of mucilage. Later the inner strata of the mucilage layer are absorbed and the protoplasm fuses with the remainder of the mucilage, the resin-bearing layer resulting from their union. Small drops of oil are formed which gradually pass into the cavity and the resin-bearing layer is ultimately almost entirely resorbed. Similar phenomena are said to occur in other resin-bearing plants.

On artificially changing the coloring of flowers, M. MIYOSHI (*Bot. Centbl.*, 83 (1900), No. 11, pp. 345, 346).—A brief account is given of experiments with alum, hydrochloric acid, and caustic potash in changing the coloring of flowers. Watery extracts were made of various red, purple, and lilac colored flowers and dilute solutions of the chemicals mentioned added. The alum changed the lilac to blue and the rose color to lilac. Hydrochloric acid changed the lilac and the light red to a copper red, and in some cases the lilac was changed to green or brown. Potash transformed the rose and lilac to green or yellow. Similar results were obtained when cut flowers were placed in solutions of the above, or by watering with them

plants grown in pots. The experiments were conducted with *Hydrangea*, *Calistephus chinensis*, *Campanula alliarifolia*, and *Licolis radiata*.

The limit of concentration of nutrient solutions for fungi, T. BOKORNY (*Allg. Bau. u. Hopfen Ztg.*, 1900, No. 51, p. 553).

A classification of the fleshy Pezizineæ, E. J. DURAND (*Bul. Torrey Bot. Club.*, 27 (1900), No. 3, pp. 463-495, pls. 6).

METEOROLOGY.

How to prevent hailstorms, P. N. KRITSKI (*Trudi Imp. Voln. Ekon. Obsch.*, 1899, No. 2, pp. 193-205).—The cause of hailstorms being, according to the author, the accumulation of electric energy in the clouds, he proposes to diminish this accumulation and thus probably entirely prevent hailstorms by means of a kite similar to that used by Franklin in his famous experiments. The kite is to be made of a rectangular piece of light fabric stretched over a wooden frame. For a wind with a velocity less than 7 meters per second kites about 4 meters in length and 2.6 in width are recommended; for a wind with a greater velocity than 7 meters per second 3.2 by 2.1 meters are suitable. The tail consists of a cord 3 mm. in thickness to which 3 cones are consecutively attached. The first cone has a diameter of 450 mm. and is situated 10 meters from the kite, the second 300 mm. in diameter is situated 4 meters from the first, and the third of the same diameter is situated 3 meters from the second. To the kite are attached 4 copper rods each 350 mm. long and 4.5 mm. in diameter. The rods each terminate in a point either made of platinum or plated with the latter and are in metallic contact with the wire (or rope) to which the kite is attached. The other end of this wire may be in contact with the earth, or with some device for storing and utilizing the electricity drawn from the sky. The kite wire need not be more than 3,500 ft. long (the mean height of the clouds). The kites should be kept flying until the danger of the hailstorm has passed.—P. FIREMAN.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review*, 28 (1900), Nos. 4, pp. 141-191, figs. 4, charts 9; 5, pp. 193-238, figs. 4, charts 8; 6, pp. 239-278, fig. 1, charts 8).—In addition to the usual reports on forecasts, warnings, weather, and crop conditions, meteorological tables and charts, and lists of recent papers on meteorology, these numbers contain the following articles and notes:

No. 4, special contributions on Special report on the floods in the Colorado Valley, Texas, April 7 to 17, 1900, and other floods during the same period (illus.), by I. M. Cline; The drought of 1899 in southwest Missouri, by J. S. Hazen; The climatology of Habana, Cuba, by E. del Monte; Phenological observations on the Potomac, by F. W. Very; and notes by the editor on death of Mr. Cyrus Ellenberger, storm waves not tidal waves, an ice storm, storm in Yucatan, local anemometric peculiarities, the seasonable rain in Colorado, freshets in James River, Virginia, phenology in Ohio, hail and its methods of formation, studies in raindrops, the formation of large raindrops, photography in meteorology, a new meteorological journal, the effects of

diminished pressure on cooking, sudden temperature changes in Montana (illus.), weather forecast cards by rural delivery, ice and navigation at St. Michael, Alaska, Oregon weather and Bering Sea ice, the Brooklyn museum of meteorology, lectures on meteorology, meteorology in the universities, the Weather Bureau and the universities, the climatology of California, and isotherms for a given altitude.

No. 5, special contributions on Special report on the floods in the Brazos River Valley, Texas, April 27 to May 17, 1900; also freshets in other streams (illus.), by I. M. Cline; Oregon weather and Bering Sea ice, by E. A. Beals; Local storm at Springfield, Mo., by J. S. Hazen; Prof. P. E. Doudna, by F. Cajori; Halo at Detroit, Mich., May, 1900 (illus.), by J. K. Hooper; Lake levels and wind phenomena (illus.), by A. J. Henry; and notes by the editor on rainfall in Jamaica for 1899, Oregon weather and Bering Sea ice, seasonal forecasts in Colorado, the thunderstorm of May 16 in Idaho, the Hawaiian standard of time, heavy rainfall in local storms, the June rise of the Missouri and Mississippi rivers, a meteorological library, monument to Cantoni, lectures on meteorology, the drift of the Gulf stream near Key West, Fla., eclipse shadow bands and correlated atmospheric phenomena, storm warnings on the Oregon coast, index to the monthly reports of the California section, and Cape Nome temperatures.

No. 6, special contributions on Extension of Weather Bureau work, by E. B. Garriott; Rainfall and drainage in the Upper Chagres River, by H. L. Abbot; Cloud-burst at Erwin, Tenn., by S. G. Worth; The seismograph at the observatory at Carson City, Nev. (illus.), by C. W. Friend; Droughts, famines, and forecasts in India, by E. D. Archibald; and notes by the editor on meteorological cablegrams, a local weather sign, climatology in California, meteorological conditions favorable to spontaneous combustion, Weather Bureau service in Haiti, the laws of atmospheric circulation, prevention of hail by cannonading, the Weather Bureau in Dominica, W. I., the Nile floods and the Indian monsoons, another use for the kite, a new meteorological journal, weather cablegrams from the Azores, and pineapple growing in southern Florida.

Meteorological summary for 1898, V. E. MUNCY (*Kentucky Sta. Rpt. 1898*, pp. XXXVII-XXXIX).—Tabular monthly summaries are given of observations at Lexington, Ky., on atmospheric pressure, temperature, precipitation, cloudiness, and wind. The mean barometric pressure for the year was 29.01 in., the highest 29.66, lowest 28.29; mean temperature 61.40° F.; the highest 96, July 2; lowest —1, December 14; total annual precipitation 60.52 in.

Meteorological observations, W. T. ELLIS ET AL. (*Canada Expt. Farms Rpts. 1899*, pp. 41, 42, 227-229, 258, 335, 388, 425).—Summaries are given of observations during 1899 on temperature, precipitation (rainfall and snow fall), and sunshine at Ottawa; Nappan, Nova Scotia; Brandon, Manitoba; Indian Head, Northwest Territories; and Agassiz, British Columbia.

Meteorological conditions of the cultural year 1898-99, P. DE CALUWE (*Exposé Cult. Exper. Jard. Gand, 1898-99*, pp. 1-5).—A summary of observations, mainly on temperature and precipitation, during the year ended October 31, 1899.

Normal distribution of rainfall in the Madras Presidency, C. BENSON (*In account of the normal distribution of the rainfall in the Madras Presidency based on the records of twenty-five years. Madras: Printed by the Superintendent, Government Press, 1899*, pp. 20, charts 16).—This is a report of the deputy director of the Department of Land Records and Agriculture. The rainfall conditions are charted and discussed with the following arbitrary divisions of the year: (1) The hot weather, April and May; (2) the southwest monsoon, June to September; (3) the northeast monsoon, October to December, and (4) the dry weather, January to March.

Storms and hail during the years 1897 and 1898 in Steiermark, Kärnten, and Ober-Krain, K. PROHASKA (*Mitt. Naturw. Ver. Steiermark, 1897*, No. 34, pp.

141-166: 1898, No. 35, pp. 141-169).—These reports record observations on lightning strokes, thunderstorms, hailstorms, etc.

The influence of forests on climate, J. SCHUBERT (*Wetter*, 17 (1900), p. 209).

On the influence of forests on the temperature of the air, MUTTRICH (*Meteor. Ztschr.* [Vienna], 17 (1900), p. 356).

The climate of Sweden according to Ekholm, ENGEL (*Geographie*, 1900, p. 199).

The Manila observatory, J. ALGUÉ (*Nat. Geogr. Mag.*, 11 (1900), No. 11, pp. 427-438, figs. 2).—An account of the history and work of this institution for meteorological inquiries.

AIR—WATER—SOILS.

Field operations of the Division of Soils, 1899, M. WHITNEY ET AL. (*U. S. Dept. Agr., Rpt. 64*, pp. 198, pls. 29, figs. 19, col. maps 11).—This is a report of progress by the Division of Soils in surveying, investigating, and mapping the soils of the United States. It contains the following papers: (1) A review of the operations of the year by the Chief of the Division, which summarizes methods used and results obtained; (2) a soil survey of the Pecos Valley, New Mexico, by T. H. Means and F. D. Gardner, which has already been noted (*E. S. R.*, 11, p. 912); (3) a soil survey of Salt Lake Valley, Utah, by F. D. Gardner and John Stewart, which has also been noted elsewhere (*E. S. R.*, 12, p. 317); (4) reconnoissances with reference to topography, soils, and alkali of Sanpete, Cache, and Utah counties, Utah, and Cache a la Poudre Valley, Colorado, by T. H. Means; (5) a soil survey in the Connecticut Valley, by C. W. Dorsey and J. A. Bonsteel, which treats of the climate, topography, geology, soils, and the culture of tobacco in that valley; (6) application of the theory of solutions to the study of soils, by F. K. Cameron; and (7) the method of mechanical analysis as applied to alkali soils and the influence of salts (sodium chlorid, sulphate, and carbonate) upon the rate of evaporation from soils, by L. J. Briggs.

Areas aggregating about 720,000 acres have been studied and mapped (on a scale of 1 in. to the mile). The maps show the areas of the different kinds of soils found in the districts studied, and, for the arid region, the alkali conditions (the distribution and relative intensity of total alkali and of black alkali) and the depth to standing water. The soil survey of the Connecticut Valley forms part of a general plan to investigate and map the tobacco soils of the United States (*E. S. R.*, 10, p. 531).

"The map shows the distribution of the soils of the valley, which are described with all necessary detail in the accompanying report. The sides of the valley are formed for the most part from the glacial deposits of Triassic sandstone, and in the northern part of diabase. The soils of the valley proper are sediments which have been washed over and assorted in the great lake which is supposed to have covered this area in prehistoric times. Some of the soils occur in well-defined terraces, which formed the shores of the old lake, or which were formed subsequently by the river and streams. Over much of the area, however, these terraces are ill-defined or

entirely lacking, and, from the differences in elevation of the same soil formation in different parts of the valley, there are even evidences to disprove the terrace theory of the physiography of the country. Certain it is, however, that the soils were laid down by water, and that in so doing they were sorted out in various grades of fineness. Beginning with the present meadows, which are composed of very fine sand and silt, the Podunk region is in a well-defined terrace elevated about 20 ft. above the meadows and is composed of one grade coarser material, but still so fine as to be just distinguishable by the eye.

"The Hartford loam, forming the principal tobacco soil, in extent at any rate, is a grade coarser than this, while the Windsor loam, believed to be the original bottom of the old lake in its shallowest portion, is very coarse sand containing some gravel. These Windsor sands produce the finest wrapper leaf when the season is favorable, but a good crop is secured only one or two years out of five."

The reconnoissances of the Sanpete, Cache, and Utah counties, Utah and the Cache a la Poudre Valley in Colorado show that the presence of injurious amounts of alkali in the soils of those regions is due to defective drainage, and the introduction of a system of underdrainage by means of tile is recommended.

In the paper on the theory of solutions as applied to the study of soils there are presented:

"(1) An outline of the theory of solutions, showing that a solute by virtue of the presence of the solvent behaves as though it were a gas, and that electrolytes present the added phenomena of electrolytic dissociation or ionization.

"(2) A demonstration that the reactions under investigation are of a reversible type, and in consequence the Mass law is applicable to a study of the equilibria among the solutes.

"(3) An application of these views, showing how the solubilities of the sulphate and carbonate of lime in nature are increased by the presence of a solute which dissociates but yields no common ion.

"(4) An announcement of the presence of sodium carbonate in the waters of the Great Salt Lake, Utah, and an explanation of why this fact has previously escaped observation, based on the relation which obtains between the ionization products and the solution constant. A similar explanation is offered for the scant amount of lime in the waters of this lake.

"(5) An examination of the hypothesis of Hilgard as to the rôle of carbon dioxide in the genesis of alkali, in which it is demonstrated that the phenomena observed are more satisfactorily accounted for in terms of the theory of solution, and that the carbon dioxide must be regarded as a contributing cause, but not a necessary one.

"(6) An examination of the Hilgard method for the reclamation of black alkali soils, with an explanation of the reactions observed and of the importance of the controlling conditions respecting drainage and the accumulation of carbon dioxide, empirically announced by Hilgard.

"(7) An examination of the reaction between calcium sulphate and the carbonates of ammonium. The use of gypsum for conserving ammonia in manure piles is explained. Some errors, with the reasons therefor, which may accompany the use of ammonium carbonate in analytical operations involving salts of the alkaline earths are pointed out.

"(8) A discussion of some analytical problems in a chemical examination of alkali soils. The nature of the problems is made clear. The relative merits of leaching the soils and taking a solution in contact with the soil in preparing the sample are discussed, and the advantages in favor of the latter procedure indicated. The necessity of making a direct estimation of each constituent is demonstrated.

"(9) A plea for the rational statement of analytical data, inasmuch as it is the ions which are determined and not the salts. Furthermore, it is the ions with which we are generally concerned in the study of any particular problem.

"(10) A field method for the estimation of sulphates, chlorids, and carbonates, involving 3 titrations which may all be made on the same sample in one vessel, Its use in reconnoissance work is described.

"(11) A rapid method for the estimation of sodium carbonate in the presence of the bicarbonate, depending on the conversion of the alkaline carbonate to the neutral acid carbonate, with the formation of a neutral sulphate by the addition of acid potassium sulphate. The use of the method in the laboratory and in the field is described, and its probable availability for technical work is suggested. The objections to the use of sulphuric acid in determining 'alkalinity' are made evident.

"(12) Observations on the hydrolysis of sodium carbonate and sodium silicate and the inversion of sodium bicarbonate and sodium bisilicate to the normal salts are described briefly.

"(13) A discussion on the formation of hardpan and similar deposits, in which it is pointed out that the hydrolysis of the salts of weak mineral acids and subsequent desiccation and deposition of the solution products must be taken into account in any hypothesis as to their genesis.

"(14) An explanation of the solution and hydrolysis of certain minerals and the consequent alkalinity they display.

"(15) Suggestions for the study of the functions of fertilizers, in which the importance of considering the solution phenomena which their presence may effect in the ground waters is made evident.

"(16) Some observations on selective absorption and other physico-chemical phenomena which are incidental to a complete study of the properties of a soil."

A paper on methods of mechanical analysis as applied to alkali soils discusses the disintegration of such soils during the progress of analysis due to the solvent action of the water used in making the mechanical separation, and describes apparatus and methods applicable to such soils, attention being called especially to the advantages of the centrifugal method for this purpose. The treatment after ignition of the mechanical separations with carbon dioxid, according to Hilgard and Jaffa, to convert the oxids of the alkaline earths into carbonates, is recommended, and the application of the electrical method (E. S. R., 11, p. 325) to the determination of the water-soluble content of soils in connection with their mechanical analysis is explained.

The conclusions from the investigations on the influence of sodium chlorid, sulphate, and carbonate upon the rate of evaporation of water from soils are summarized as follows:

"(1) Salts influence the evaporation of water from the surface of a soil by changing the surface tension, the viscosity and the vapor pressure of the system, and the physical character of the soil, particularly at the surface.

"(2) The surface tension and viscosity influence the rate of evaporation only through the modification of the rate of capillary movement. Both surface tension and viscosity increase with increase in concentration. An increase in surface tension increases the rate of capillary movement, while increase in viscosity diminishes it. These two factors consequently oppose one another.

"(3) The rate of capillary movement within a soil is of secondary importance to the physical character of the surface, as modified by the presence of crystallized salts.

"(4) The relative rate of evaporation from a soil moistened with pure water and

salt solution, respectively, is the same as for the water and solution without the soil, providing no surface mulch is formed.

“(5) The rate of evaporation gradually decreases with increase in concentration.

“(6) The diminution of evaporation with increasing concentration is much less than the corresponding diminution in vapor pressure. This is due to the fact that the atmosphere is never vapor free, and that the diffusion of water vapor is retarded by the surrounding air.

“(7) The diminution of evaporation of soils containing solutions of ‘alkali’ salts is much greater than can be accounted for through the influence of the lower vapor pressure, and is due to the formation of a mulch at the surface of the soil through the crystallization of the salts.”

A study of the physical properties of clay as related to soil structure, V. H. DAVIS (*Agr. Student*, 7 (1900), No. 1, pp. 15-18).—This is an abstract of a thesis presented to the faculty of the Ohio State University in 1900. Tests of the tensile strength of wet ground brick and clay from the university campus by a modification of G. E. Ladd's method and of the breaking strength of dry brick of the same material are reported. It was found that the tensile strength of a wet substance having no inherent plasticity, such as the ground brick used in these experiments, was practically independent of the size of the particles. With a substance naturally plastic, like the clay, the tensile strength increases as the size of the particles decreases. A great difference was found in the breaking strength of the wet and dry substances. The conclusion is drawn “that fineness of particles accompanies plasticity and is essential to it, but is not in itself a cause of plasticity, and that the real cause is yet to be determined.”

The moisture of the soil under the pine forest of the Khrenov estate, G. MOROSOV (*Selsk. Khoz. i Lysosr.*, 196 (1900), Mar., pp. 481-519).—The forest is situated on dune hills. The moisture was determined at the depths of 10 cm., 25 cm., 50 cm., 1 meter, 1½ meters, and 2 meters. The author's results corroborate those obtained by Visotski, who arrived at the following conclusions: (1) The upper surface of the soil dries out most where it is most open, as, for instance, on black fallow, and least under forest; (2) the soil as a whole dries out most under virgin soil covered with grass, next under forest, and least under black fallow; and (3) the subsoil dries out most under forest, next under virgin soil, and least under black fallow.

In addition the author found that: (1) The subsoil under forests in the spring is more moist than in the open, and only later on does it dry out more than under the latter; (2) the soil is not in all cases more moist under forests than under treeless areas. There are certain sandy soils covered with pines in which the upper layers, except in the early spring, are drier than in treeless areas.—P. FIREMAN.

The air, H. BLÜCHER (*Die Luft. Ihre Zusammensetzung und Untersuchung, ihr Einfluss und ihre Wirkungen, sowie ihre technische Ausnutzung.* Leipzig: Otto Wigand, 1900, pp. XII+322, figs. 34).—This book treats of the constituents and impurities of air, its physical properties, including the meteorological phases of the subject; physical,

chemical, and bacteriological studies of the air, as related to its properties and variations; the influence of the air on organic and mineral substances and on the plant and animal worlds, including weathering, decomposition, respiration, nitrification, assimilation of nitrogen by plants, transmission of plant and animal diseases, etc.; and the technical uses of air in pumps, windmills, etc., and in compressed and liquid form. The book contains name and subject indexes and numerous references to literature.

The carbon dioxid of the atmosphere, E. A. LETTS and R. F. BLAKE (*Sci. Proc. Roy. Dublin Soc.*, 9 (1900), II, pp. 107-270; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 455, II, p. 622).

Well waters from farm homesteads, F. T. SHUTT (*Canada Expt. Farms Rpts. 1899*, pp. 155-157).—Analyses of 49 samples of water from different parts of Canada with reference to sanitary condition are reported.

Mineral waters, A. M. PETER and H. E. CURTIS (*Kentucky Sta. Rpt. 1898*, pp. XXIII-XXVIII).—Partial analyses of 19 samples are reported.

A comparative study of the methods used for the measurement of the turbidity of water, G. C. WHIPPLE and D. D. JACKSON (*Tech. Quart.*, 13 (1900), No. 3, pp. 274-294, figs. 4).—On the basis of the investigations here reported, the use of the silica standard for the determination of turbidity in water is recommended.

The question of the drying up of rivers in its past and present status, E. OPOKOV (*Selsk. Khoz. i Lysov.*, 197 (1900), June, pp. 633-706).—On the basis of observations on the Dnieper and Volga the author combats the prevalent opinion that Russian rivers are decreasing in volume. He concludes that the life of rivers and the quantity of water in them depend chiefly on the size of their drainage basins and the quantity and conditions of the precipitation. The influence of a decrease of the area of forests and marshes is only of secondary importance and is commonly greatly exaggerated.—P. FIREMAN.

A normal chlorin map of Long Island, G. C. WHIPPLE and D. D. JACKSON (*Tech. Quart.*, 13 (1900), No. 2, pp. 145-148).—This map, based on analyses of 80 samples of water, shows that, except at the eastern end of the island, the normal chlorin is below 6 parts per million of water.

Drainage for alkali spots, C. E. MEAD (*New Mexico Sta. Bul. 33*, pp. 39, 40).—A brief account is given of an attempt to remove the soluble salts from a "chico" or alkali spot by means of open ditches and flooding.

The condensation of water vapor by the soil, E. WOLLNY (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 19, pp. 700-705; 20, pp. 739-746).—The author discusses this subject at some length and concludes that the power of soils to condense water vapor from the air is of no practical value, either directly or indirectly.

Lectures on some of the physical properties of soil, R. WARINGTON (*Oxford: Clarendon Press; London: Henry Frowde, 1900*, pp. XV+231, figs. 6).—This book gives the substance of a course of lectures delivered in 1896 by the author as Sibthorpe Professor of Rural Economy in Oxford University. It does not claim to be a textbook dealing exhaustively with the physical properties of soils, but lectures discussing with some fullness particular phases of the subject. "In these lectures the attempt has been made to treat every subject from an experimental point of view, and a considerable space will be found occupied by accounts of the investigations which appear to have thrown most light upon the subjects discussed." Liberal use is made of station literature, especially that published by the American stations, since the English literature on the subject is very limited. Acknowledgment is made of special indebtedness to the work of Hilgard, King, and Whitney. The book contains chapters on the physical constitution of soil, relations of soil to water and to heat, and movements of salts in the soil. It is the intention of the author to follow this work with a treatise on the chemistry of soil on a similar plan.

The action of the wind on the soil, M. STAHL-SCHRÖDER (*Selsk. Khoz. i Lysov.*,

196 (1900), *Feb.*, pp. 363-378).—The author discusses the influence of winds on the moisture, temperature, and gas content of the soil; on chemical composition; and as a geological agent.—P. FIREMAN.

The humidity of the soil and subsoil in wooded and bare steppes in Russia, G. WISSOTZKY (*Ann. Sci. Agron.*, 1900, II, No. 1, pp. 120-138, figs. 4).—The drying action of forests on the soil moisture is shown in this article, also that there exists in soils what is termed a "dead" zone which is never reached by the percolating rainfall.

Description of a soil map of the Connecticut Valley, M. WHITNEY (*U. S. Dept. Agr., Division of Soils Circ.* 7, pp. 4).—This circular describes briefly the conditions in the Connecticut Valley and the soils represented on a map published in connection with a more detailed report on the subject (see p. 522).

Canadian soils, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 132, 133).—Analyses of 3 samples of soil, 1 from Manitoba and 2 (virgin and cultivated soil) from New Brunswick, are reported and discussed.

Economical improvement of exhausted soils, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 133-137).—This is a general discussion of this subject, treating of the effect of continuous cropping without the application of manure and the features which characterize partially exhausted soils, including poor texture, deficiency of humus and nitrogen, and sourness and deficiency of lime.

Reports of the work of the western expedition for the reclamation of marshes, 1873-1898, I. I. ZHILINSKI (*Selsk. Khoz. i Lygosov.*, 198 (1900), July, pp. 229-234).—This is a review of two reports, aggregating about 1,040 pages, with an atlas containing 77 maps, plans, etc., published by the Ministry of Agriculture and Imperial Domains at St. Petersburg. The work done by this expedition was confined chiefly to that section of European Russia which embraces the governments of Minsk, Grodno, and Volyn. The entire work cost 4,780,000 rubles (\$3,680,600).—P. FIREMAN.

FERTILIZERS.

On the availability to grass of nitrogen in form of nitrate of soda, cotton-seed meal, and fine, hard bone, E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 197-203).—The experiments here reported were in continuation of those of previous years (*E. S. R.*, 11, p. 722). January 7, 1899, nitrate of soda, cotton-seed meal, and raw-knuckle bone flour were each applied to 4 pots seeded to grass, of the series used in the previous experiments, at rates furnishing 0.1333 gm. of nitrogen per pot. The experiments were conducted and the yields and nitrogen content of the crop were recorded as in previous years.

"The yields in 1899 were without exception much less than in 1898. This may have been due to a lack of available potash in the second year, to difference in the amount of sunlight, or to possible change in the mechanical condition of the soil, caused by the watering.

"The important fact brought out by the cultures is that in this soil and under the conditions of our experiment, while the nitrogen of nitrate of soda and cotton-seed meal very largely increased the crop and the crop nitrogen, the nitrogen of fine, hard, raw-knuckle bone had absolutely no effect of this kind.

"There is no evidence that the fertilizer nitrogen of hard raw bone, applied 2 years ago, has yet been assimilated in any amount by grass which has been growing continuously in the soil with it."

On the availability to Hungarian grass of nitrogen in form of nitrate of soda, cotton-seed meal, and raw, boiled, and steamed bone. E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 204-210*).—This is a continuation of experiments of previous years (E. S. R., 10, p. 234). The soil used was a light sand containing 0.1095 per cent of nitrogen and having a faintly acid reaction to litmus paper. To the soil of each pot were added 6.6 gm. of freshly slaked lime free from magnesia, 1.8 gm. of muriate of potash containing 48.54 per cent of potash, and 1.2 gm. of dicalcium phosphate containing 41.5 per cent of phosphoric acid, besides the nitrogenous fertilizers tested. The experiments were conducted as in previous years. The results are summarized in the following table:

Percentages of crop increase and of fertilizer nitrogen recovered in Hungarian grass.

Fertilizer used.	Nitrogen content.	Rate of application per acre.	Crop increase.	Fertilizer nitrogen recovered in crop.
	<i>Per cent.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Nitrate of soda.....	16.08	462	46	79
Do	16.08	231	25	62
Cotton-seed meal	8.42	871	28	38
Do	8.42	436	18	44
Hard raw bone	4.16	1,760	-1.7	1.3
Do	4.16	880	.7	-26.6
Soft raw bone	3.98	1,840	16.3	8.8
Do	3.98	920	4.3	10.0
Steamed bone	2.31	3,170	19.1	8.5
Do	2.31	1,585	4.8	-13.9
Boiled bone	2.77	2,650	5.3	-1.2
Do	2.77	1,325	3.0	-32.3

"Inspection of these figures shows that from 62 to 79 per cent of the fertilizer nitrogen in form of nitrate of soda and from 38 to 44 per cent of the fertilizer nitrogen in form of cotton-seed meal were available and taken up by the crop.

"The results where bone nitrogen was applied are very irregular, and much less nitrogen was present in some crops which had grown in pots to which bone was added as a fertilizer than in crops from pots which had no fertilizer nitrogen added to them. In no case where bone was used as a fertilizer did more than about 8½ per cent of the fertilizer nitrogen become available to the crop. In every case the larger application of bone had a better effect than the smaller one."

On the availability of the nitrogen of hard raw bone as affected by applications of slaked lime. E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 211-216, pl. 1*).—Experiments on this subject, similar to those described above, were made with 3 light sandy loams deficient in available plant food. The pots used were brought to a uniform weight of 5 lbs. by putting in gravel, and 14 lbs. of soil containing 15.69 per cent of moisture was placed in each pot. The fertilizers used per pot were 1.8 gm. of muriate of potash, 1.2 gm. of dicalcium phosphate, and 6.4 of fine, hard knuckle bone. Two pots received no lime; two, 6.6 gm. of lime; two, 13.2 gm.; two, 19.8 gm.; and two 26.4 gm. of freshly slaked but

dry lime containing only traces of magnesia. Hungarian grass was the plant grown. From the data for crop increase and nitrogen in the crop the following conclusions are drawn:

“(1) An application equal to 1,800 lbs. of slaked lime per acre decreased the yield of grain by 11 per cent, of straw (including roots and stubble) by 19 per cent, and of crop nitrogen by about 14 per cent.

“(2) An application equal to 3,600 lbs. of slaked lime per acre, instead of further decreasing the yield, increased the yield of grain by 13 per cent and of crop nitrogen by 10 per cent, while the yield of straw and stubble was 14 per cent less than where no lime was applied.

“(3) Applications equal to 5,400 and 7,200 lbs. of slaked lime per acre increased the crop as follows:

Percentage increase over crops from soil to which no lime was added.

	5,400 lbs. of lime per acre.	7,200 lbs. of lime per acre.
	<i>Per cent.</i>	<i>Per cent.</i>
Increase of grain.....	36.8	43.7
Increase of straw.....	1.2	1.9
Increase of crop nitrogen.....	38.1	54.1

“In these cultures, therefore, in which hard raw bone was used as a fertilizer, applications of large quantities of slaked lime (two and three times as much lime as bone) increased the grain in the crop by 36 to 44 per cent and the crop nitrogen by 38 to 54 per cent over the yield from pots to which no slaked lime was added; but the yield of straw was not increased by the use of lime. From this series alone can not be calculated the actual percentages of the fertilizer nitrogen recovered in the crop, for the yield of crop nitrogen from the soil without fertilizer is not determined nor the effect of the lime in making the soil nitrogen available. Further experiments are being made on these points. These cultures, however, prove that slaked lime has made very much more available the nitrogen of the soil, or more probably, the nitrogen of the bone which without lime was almost inert as a fertilizer.”

The comparative value of nitrate of sodium and sulphate of ammonium as manures, R. WARINGTON (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. 2, No. 42, pp. 300-346).—A general discussion of this subject based largely upon the results of experiments at Rothamsted and Woburn. It is shown that ammonium sulphate is slower in action than sodium nitrate because it must first undergo nitrification. When the conditions are unfavorable to nitrification, that is, when the soil is deficient in lime and the season is dry, sodium nitrate, being soluble and immediately available as plant food, gives better results than ammonium sulphate. In a wet summer, however, and on a soil abundantly supplied with lime, ammonium sulphate frequently gives better results than sodium nitrate. “This influence of climate is most clearly seen in the case of cereal crops, or on grass lands; it is less perceived in the case of crops like potatoes and mangels, which have a longer period of growth.” It is stated that the slower action of ammonium sulphate as compared with sodium nitrate is not entirely

due to the time required for the nitrification of the salt itself, but is partly due to its action in retarding nitrification in the soil.

"An application of nitrate of sodium does not apparently interfere with the ordinary course of nitrification in the soil, this goes on as if no nitrate has been employed; but when an ammonium salt is applied to the soil, nitrification seems to proceed first on the ammonia, and the nitrogenous organic matter of the soil in contact with the ammonia is protected for a time from decomposition, and reserved for a later action. This effect of adding ammonium salts to a soil will be distinctly increased if the proportion of carbonate of lime in the soil is very small, so that the immediately available base is used up by the ammonium salts, and a fresh supply is obtained only by subsequent weathering."

Averaging the results of a long series of field experiments at Rothamsted, it is found that the effectiveness of ammonium sulphate as compared with that of sodium nitrate was for cereal crops as 93 to 100 for the grain and 79 to 100 for straw, for hay as 88 to 100, and for mangels 82 to 100. In experiments with potatoes the product from the ammonium sulphate was on an average fully equal to that yielded by sodium nitrate. In experiments on turnips in Scotland and the north of England, in which small quantities of ammonium sulphate and sodium nitrate were applied, the 2 fertilizers were about equally effective.

The profitableness of fertilizing, E. WOLLNY (*Illus. Landw. Ztg.*, 20 (1900), Nos. 83, pp. 789, 790; 84, pp. 800, 801; 85, pp. 809, 810).—A popular discussion of this subject.

The decomposition of organic substances and the forms of humus in their relations with agriculture, E. WOLLNY (*Ann. Sci. Agron.*, 1900, II, Nos. 1, pp. 33-119, figs. 2; pp. 338-450).—This is the conclusion of the article which has been referred to in previous numbers of the Record (E. S. R., 11, p. 917).

Niter earth, wood ashes, and phosphatic material, A. M. PETER and H. E. CURTIS (*Kentucky Sta. Rpt.* 1898, p. XVI).—Analyses of 4 samples of niter earth, 3 samples of wood ashes, and 1 sample of phosphatic material are reported.

Utilizing blast-furnace slag as a fertilizer, A. D. ELBERS (*Tradesman*, 44 (1900), No. 7, pp. 91, 92).—This article treats briefly of "the practicability of using highly calcareous slag for agricultural purposes in place of ordinary lime, chalk, and marl." It does not deal with the phosphatic slags.

Researches on the injurious effects of nitrate of soda, P. DE CALUWE (*Exposé Cult. Exper. Gand*, 1898-99, pp. 54-66, pls. 3).—A detailed account of the experiments noted above.

Commercial fertilizers in Indiana, H. A. HUSTON (*Purdue Univ. Spec. Bul.* 1900, Aug., pp. 24).—This is a report of analyses of 481 samples of fertilizers examined during 1899, with a discussion of the results.

"[Of the samples examined] only 39 were up to the legal standard in every particular. One hundred and twenty samples fell below the legal standard in one or more ingredients, but the differences are so small that a purchaser, while not getting the full amount legally due him, yet got so nearly that amount that he was not seriously misled in regard to the relative amounts of each ingredient present, nor was he subjected to any considerable financial loss. . . .

"Three hundred and twenty-two samples differ so much from the legal standards that the purchaser would be seriously deceived. In many cases less than one-half the legal amount of one or more ingredients was present."

Fertilizers and amendments, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 137-143).—Analyses of the following fertilizing materials are reported and their value

and use briefly discussed: Marsh mud, swamp muck (19 samples), tannery ashes from the furnace and from the heap, wood ashes, fish pomace, sewage sludge, and poudrette.

FIELD CROPS.

Field experiments at the experiment farm at Lauchstädt in 1897 and 1898, M. MAERCKER (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 617-943, 995-1047, *abgm.* 1).—A special feature of the experiments has been the different methods of fertilizing adapted to crops grown in succession according to the Norfolk system of rotation, *i. e.*, winter wheat, sugar beets, spring barley, and potatoes. Other special features have been the utilization of barnyard manures from different sources and when preserved by different methods. Earlier work has been noted (*E. S. R.*, 10, p. 533).

When alfalfa hay was grown on a clay soil at the station its chemical composition was but little affected by fertilizing with Thomas slag alone or combined with kainit and gypsum. Its feeding value was decreased, if anything, by the use of these fertilizers. The use of 600 kg. of Thomas slag and 1,000 kg. of kainit combined per hectare greatly increased the yield of an old alfalfa field and had a remarkably good effect on newly seeded fields. Thomas slag alone gave indifferent results. The addition to the Thomas slag and kainit of 1,000 kg. of gypsum per hectare increased the yield nearly 25 per cent. It is thought this same result would have been obtained by a larger use of potash. Fifty per cent of the potash in the kainit applied was utilized by the crop when gypsum was applied at the same time, whereas without it 44.3 per cent was utilized. The application of 2,000 kg. per hectare of Thomas slag at one time in combination with 1,000 kg. of kainit, in the expectation that about 500 kg. of the slag would be needed yearly for the crop, nearly doubled the yield the first year, paid the whole cost of the fertilizer, and left a profit of nearly \$6 per hectare besides.

In the tests with varieties of winter wheat, Square Head sorts have regularly surpassed all other varieties in the yield of both grain and straw, and the use of Improved Square Head seed gave average results which exceeded by 263 kg. per hectare the yields obtained from seed wheat of the same variety generally grown in the vicinity of the station. In the opinion of the author the profit in growing wheat depends as much upon the use of selected seed as upon the cultural methods followed or the fertilizer employed. The Square Head varieties Strube and Beseler No. 3 stood up the best under heavy applications of nitrogenous fertilizers of all the varieties tested. Rimpau Bastard was the earliest variety grown and proved best adapted for poor soils. Fall applications of nitrate of soda have not proven profitable. Applying one-half of the nitrate of soda at the end of February

and the other half at the end of May increased the grain yield 308 kg. per hectare over applying the same total amount early in the spring. In general, no spring applications of nitrogenous fertilizers are made if the wheat crop presents a good appearance. Commercial fertilizers were most effective on wheat when the crops immediately preceding had received either green or barnyard manures. Increasing the application of nitrate of soda beyond 200 kg. per hectare, while profitable in a few cases, in general tended to produce straw, which lodged badly and caused a decrease in the yield of grain. Thomas slag was most effective in the presence of nitrogenous fertilizers. Phosphoric acid in a water-soluble form has given better results with wheat than applications of equal amounts of citrate-soluble phosphoric acid.

Variety tests with winter rye resulted in placing Heine Zeelander and Lowchow Petkuser at the head of the list of desirable varieties for growing at the station. Treating rye seed with Alinit did not increase the yields.

Of the peas grown, Strube Early Victoria was the earliest and best yielding variety. A light application of barnyard manure or of nitrate of soda in the early stages of growth was found very beneficial for peas, and is recommended.

Oats followed different combinations of leguminous plants used as nitrogen gatherers. The best yield of both grain and straw followed a mixture composed of 50 per cent horse beans, 25 per cent peas, and 25 per cent vetch. Results obtained with Nitragin were conflicting. An application of 200 kg. per hectare of nitrate of soda increased the crop of oats following alfalfa 101 kg. over an application of 100 kg. of nitrate of soda. Winter oats were not grown with profit.

Of a number of varieties of barley grown, Hanna stood first as regards yield, both in 1896 and 1897. In 1898 Selchower headed the list. Heine Improved Chevalier barley has regularly produced the largest yields of straw. The Hanna barley ripened from 5 to 10 days earlier than any other sort grown. It also proved especially well adapted for culture on light soils when fertilized with potash and phosphoric acid, a feature which it is thought will contribute largely toward furthering the culture of barley in Germany. The variety Goldthorpe, though below some others in yield, was, nevertheless, one of the most satisfactory grown. In extract material, color, fineness, and size of grain, it outranked every other variety grown. Its chemical composition was least injuriously affected by fertilizers. It stood up well under all conditions. It was not a good variety for light soils, but proved especially valuable on soils too rich in nitrogenous fertilizers for the satisfactory culture of other varieties. Potash fertilizers on barley usually increased the grain yield, and whenever that occurred an improvement of the quality of the grain for brewing purposes by

an increase in starch content and a corresponding decrease of the protein content followed. Sylvanit as a source of potash proved a complete substitute for kainit, and is preferred by the author for barley. While the yields obtained with nitrate of soda were somewhat larger in all cases than with Peruvian guano, the composition of the grain was much better on plats fertilized with Peruvian guano, the color of the grain was better, and the extract on an average 4.3 per cent higher. The author considers Peruvian guano a far better fertilizer for barley than nitrate of soda. Experiments during the unfavorable season of 1898 showed sulphate of ammonia to be as satisfactory a source of nitrogen as Peruvian guano. Winter barley gave better yields on light soils than rye, and was fairly satisfactory as a barley for brewing purposes.

In experiments with sugar beets large leaf development and high sugar content of the root were found to be interrelated. Beet seed grown by reliable seedsmen gave better yields and produced beets having a higher sugar content and percentage purity than seeds of the same variety grown by a sugar-beet factory. Potash applied to sugar beets increased the yield considerably, but tended to decrease the sugar content of the beet roots. Up to a certain limit each application of 100 kg. of nitrate of potash increased the average yield of sugar beets 2,500 kg. per hectare. Sugar beets grown after catch crops turned under in the fall resulted in considerably increased yields over sugar beets grown after catch crops plowed under in the spring. Considerable decrease in yield regularly followed the omission of phosphoric acid from fertilizer formulas employed. The use of phosphatic fertilizers exerted no regular or marked influence on the sugar content of the beet roots. Superphosphate proved better than Thomas slag as regards the yield of roots. Catch crops used as nitrogen gatherers for sugar beets regularly increased the yield. They were most effective with regard to yield and profit when accompanied by applications of phosphoric acid.

Sheep manure on sugar beets increased the yields over deep-stall manure and had no depressing effect on the percentage sugar content and purity. Supplementing either deep-stall or common-stall manure with 200 kg. of nitrate of potash per hectare resulted in a profit, but doubling or trebling this amount did not increase the profits.

Of the varieties of potatoes grown in 1897, Prof. Maercker and Geheimrat Theil gave the best yields, 26,400 and 22,833 kg. per hectare, respectively. In 1898 Silesia led with a yield of 34,317 kg. per hectare. The use of kainit decreased the average starch content of the potatoes grown 1.91 per cent. On the station soil phosphoric acid used alone increased the yields 504 kg. per hectare. When used in combination with barnyard manure it increased the yields 2,060 kg.

per hectare. The use of nitrate of potash proved most profitable when combined with phosphoric acid, barnyard manure, or green manures.

In 1897 and 1898 barnyard manure from deep stalls produced yields of 321 and 465 kg. per hectare, respectively, more than barnyard manure obtained from common stalls. Plowing under catch crops in the fall, rather than the spring, has given best results for potatoes.

Some experiments were made with field-crop seeds. A portion of the seeds grown at the station were sent out to farmers for comparison with the seeds usually employed by them. In general, the station-grown seeds gave considerably better results.

In investigations with green manures it has been found that these manures possess the same high value for better soils as for lighter soils. Green manuring was found profitable with every crop, but proved especially valuable for sugar and fodder beets, potatoes, and carrots.

The most suitable plants for green manuring consisted of a mixture of 50 per cent of horse beans, 25 per cent of vetch, and 25 per cent of peas. Plowing the green manure under in the fall gave best results, except with crimson clover or a mixture of hairy vetch and rye, which, when sown late in the season, made its greatest development in the spring. Phosphatic and potash fertilizers were profitably used with green manures, but nitrogenous fertilizers were hardly necessary.

The experiments to determine the economic use of barnyard manure involved the utilization on different crops of barnyard manure from deep and from common stalls, of sheltered and unsheltered manure, barnyard manure sprinkled with a weak solution ($1\frac{1}{2}$ to 2 per cent) of sulphuric acid, and manure preserved with a mixture of marl and peat and with "sulfarin," a fertilizer-preserving mixture composed of sulphate of magnesia containing 15 to 18 per cent of free sulphuric acid. The best results with sugar beets and potatoes have been obtained with barnyard manure from deep stalls preserved under shelter. When barnyard manures were used, the further addition of commercial nitrogenous manures was not profitable. Additions of phosphoric acid, on the other hand, gave largely increased returns. Treating barnyard manures with a $1\frac{1}{2}$ to 2 per cent solution of sulphuric acid preserved the ammonia in the manures and profitably increased the yields. The use of "sulfarin" in preserving barnyard manure rendered the manure much more effective, but its high cost made the use of sulphuric acid for this purpose more economical. Treating stall manure with 5 per cent of its weight of marl increased the potato crop 241 kg. per hectare. When 2 per cent of peat moss was added, the yield was increased 430 kg. per hectare. These results were not quite as good as those obtained with the barnyard manure treated with sulphuric acid. The method used for incorporating sulphuric acid with the manures has been noted elsewhere (E. S. R., 11, p. 725).

When marl is used as a barnyard-manure preservative about 20 lbs. per head per day is required for large stock, when the marl contains but 20 per cent of carbonate of calcium. If the marl contain 50 per cent of carbonate of calcium, only about $12\frac{1}{2}$ lbs. per head per day are required. Marl is much more effective if used in connection with peat moss. About 2 lbs. of peat moss should be kept in the gutter behind each animal to absorb all liquid manure and should be changed about twice each week.

Field experiments with farm crops, W. SAUNDERS, J. H. GRISDALE, W. T. MACOUN, R. ROBERTSON, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts. 1899, pp. 5-33, 35-38, 65-72, 105-109, 113-117, 229-249, 283-310, 337-362, 389-410, figs. 6*).—As in previous years, variety, cultural, and fertilizer tests with cereals, root, and forage crops have been carried on at the government experimental farms in Ottawa, the Maritime Provinces, Manitoba, British Columbia, and the Northwest Territories (E. S. R., 11, p. 831). The results of the variety tests with the different farm crops in 1899 have been previously recorded (E. S. R., 12, p. 134). The cultural experiments consisted of early, medium, and late sowings of oats, barley, spring wheat, peas, turnips, mangels, carrots, sugar beets, potatoes, and flax; distance experiments with corn, soy beans, horse beans, and potatoes; early and late harvesting of root crops; rotation tests; thick and thin seedings of grasses; spring and fall plowing and summer fallowing; growing mixed grain crops together, etc. The fertilizer experiments include tests of barnyard manure and different commercial fertilizers and of the relative value of clovers, rye, peas, tares, alfalfa, rape, and brome grass as green manures. The results of these experiments are tabulated in detail and in some instances averaged for preceding years.

On the whole the crops obtained at the experimental stations in 1899 have been above the average for the country, due, it is thought, largely to a more thorough preparation of the soil, greater care in the preservation and use of barnyard manure, the careful selection of well-matured and plump seed of the most productive sorts, and early sowings. The relative earliness of ripening of the different cereals, which is considered almost as important as productiveness, has been further investigated and the result reached that, as a rule, "any great increase in earliness and ripening of grain is accompanied by a decrease in yield."

The results of experiments in early, medium, and late sowings of oats, barley, and wheat for 10 years, and of peas for 5 years at the Ottawa farm are summarized and are shown to have been uniformly in favor of the second sowing; that is, about 1 week after the ground is in that condition where sowing is practicable. A further delay of 1 week has caused an average loss with oats of over 15, barley 23,

spring wheat 30, and peas 4 per cent. With a delay in sowing of 4 weeks, the average loss with oats has been 48, barley 46, spring wheat 56, and peas 30 per cent. These results are largely in harmony with like data reported from the branch stations. Early sowings of mangels, carrots, and beets at all the stations have resulted quite uniformly in favor of the practice. At the Central Station the yield of potatoes decreased regularly with the lateness of planting after May 26, when the first crop was put in the ground. With the flax crop in 1899 the results in the Maritime Provinces, Northwest Territories, and British Columbia seem to be in favor of medium sowings.

In the distance experiments, corn was grown in rows 14, 21, 28, 35, and 42 in. apart, respectively. In general the heaviest yields of green silage corn were obtained from the rows 21 and 28 in. distant, when cut in the early milk stage. With soy beans and horse beans the largest yields at Ottawa, Manitoba, and the Northwest Territories were obtained when the rows were 21 in. apart. Twenty-four in. for soy beans and 30 in. for horse beans were found to be the best distances in the Maritime Provinces; while 35 for soy beans and 28 for horse beans were found best in British Columbia. Leaving a part of the turnips in the ground 3 weeks after the first pulling, October 14, resulted in considerably increased yields at the Ottawa Station.

Spring-plowed land has usually proved better than fall plowed for wheat in Manitoba, while summer fallowing has given better results than either. Seeding wheat with a press drill has given better average yields of grain for 8 years in the Northwest Territories than seeding with a hoe drill. Likewise at the same station seeding wheat 2 in. rather than 3 in. deep has given the better average results for the same period, while the use of $1\frac{1}{4}$ to $1\frac{1}{2}$ bu. of seed per acre has resulted more satisfactorily than when only 1 bu. per acre has been sown.

Of all the different fertilizers used at the Central Farm on spring wheat, barley, corn, mangels, and turnips, the best average results for 12 years have been obtained with barnyard manure (about equal parts horse manure and cow manure), and slightly better results have been secured from the use of fresh manure than from well-rotted manure. At the same station oats grown after grain crops seeded with clover in 1897 gave an increase in yield of straw of 17 per cent in 1898 and 35 per cent in 1899; and of grain of over 28 per cent in 1898 and 29 per cent in 1899, as compared with the yield from the grain plats on which no clover had been turned under.

Growing oats after pasture grass and clover has resulted in better yields of grain than growing after either brome grass, pasture grass, or barley seeded with clover. Potatoes grown after a crop of barley and clover gave a 28 per cent higher yield than when grown after peas and carrots.

On a rather rich moist sandy loam soil at the station in Manitoba,

green manuring for wheat and oats was without benefit, the best results being secured from summer fallowing. Soy bean was one of the best preparatory crops for barley. At the Experimental Farm for the Northwest Territories plowing under green crops preparatory for a crop of wheat was without benefit, the soil being seemingly sufficiently well supplied with humus and nitrogen. In the Maritime Provinces barnyard manure alone, and mixed with commercial fertilizers, has given better results with farm crops than complete commercial fertilizers or single elements.

Inoculating clover seed with Nitragin seemed slightly beneficial in Manitoba and the Northwest Territories, while in British Columbia better results were secured from untreated seed.

Some experiments were made at the different stations to learn the best amounts of mixed grasses to sow for the heaviest yields, and whether better results could be obtained from mixing grain than from seeding alone. In the Maritime Provinces seeding mixtures composed of 2 bu. of oats, 1 bu. of barley, and $\frac{1}{2}$ bu. of peas, at the rate of 3 bu. per acre, gave higher yields of grain than smaller amounts. At the Manitoba Station there was an average difference in yield of but 55 lbs. per acre in favor of sowing mixed grains, rather than growing the grains separately. In British Columbia a mixture of 1 bu. each of peas, oats, and wheat gave a slightly higher yield than a similar mixture of peas, oats, and barley. In seeding experiments with different grasses the average results for 3 years at the Manitoba Station showed that with timothy and western rye grass, 10 lbs. of seed is sufficient, while with brome grass and bald rye grass, 20 lbs. gave the best results, and with American lyme grass, 15 lbs. was most desirable.

At the Central Farm an experiment was conducted in planting potatoes at different depths from 1 to 8 in. Level cultivation was adopted and so but little soil was thrown on the potatoes after they were planted. The best average yields for 2 years were obtained when the potatoes were planted but 1 in. deep. "Notes were taken on the depths at which tubers were formed and it was found that most of them were within 4 in. of the surface of the soil, even where the seed had been planted 6, 7, and 8 in. deep. Where the sets were planted less than 4 in. deep, nearly all the tubers were found between that and the surface of the soil."

Experiments with oats for the prevention of smut were carried on at nearly all the stations. Soaking oat seed for 1 hour in formalin ($4\frac{1}{2}$ oz. to 10 gal. of water) or $\frac{1}{2}$ hour in a copper sulphate solution (1 lb. to 5 gal. of water) has quite uniformly prevented loss from this source.

A variety test with 48 varieties of tobacco was conducted at the Central Station, as to time of ripening and productiveness. The results are tabulated but no conclusions drawn.

Corn culture in North Carolina, B. IRBY (*North Carolina Sta. Bul. 171, pp. 27-43*).—This is a popular practical bulletin on corn culture, dealing in detail with the following subjects: Kinds of land suited for corn culture, preparation of the soil, planting, fertilizers to be used on corn, methods of corn cultivation, rotations for corn, varieties best adapted to the South, harvesting the crop, selection and improvement of seed, protection against weevils and moths, and the comparative food value of corn and other forage crops. Dent varieties of corn are considered best for the South, and for grain and stover purposes the One-Hundred-Day Bristol, Delaware County Dent, Leaming, Golden Beauty, Chester County Mammoth, White Cap Early Dent, among the yellow varieties, and Mortgage Lifter, Hickory King, Mammoth White Hite, Riley Favorite, Cory Klondike, Snow Flake, Mosby Prolific, and Red Cob, among the white varieties, are considered best. For grain and silage purposes Cocks Prolific, Northern White Field, Blount Prolific, White Dent, Red Cob Ensilage, and Southern Horse Tooth, are recommended.

Sowing the seed with a planter is advised when as much as 10 acres of corn is grown. The seed for planting should be selected from the stalks in the field rather than in the crib.

Crops for alkali soils, C. E. MEAD (*New Mexico Sta. Bul. 33, pp. 37-39*).—A brief account of the successful culture of sugar beets and sorghum on alkali patches or "chico spots," which are common on many of the farms in the northwestern part of New Mexico. Sugar beets grew especially well on these alkali spots, the roots being of large size and good shape analyzing 18 to 20 per cent of sugar in the juice with a purity of from 80 to 90.

In the sorghum experiment the soil of a "chico spot" was removed to a depth of about 1 ft. and distributed over the remainder of the plat as evenly as possible. The excavation thus caused was filled with soil containing very little if any alkali. It was leveled and the whole plat drilled to sorghum. "In the fall, when the cane was stacked, the stalks on the 'chico spot' were large and tall and most of them matured their seed, while those on other parts of the same plat were small, short, and of a sickly-looking color and in very few instances could a ripe head be found. There was a difference of fully 2 ft. in the height of the canes on the plat in favor of the ones grown over the 'chico' land, and the heads of these were large and well filled with grain, while the same can not be said of the others."

Grasses and forage crops, C. A. KEFFER (*New Mexico Sta. Bul. 32, pp. 19-31*). The author discusses briefly the importance of combining live stock and crop interests on the same farm in New Mexico and urges the growing of certain forage crops for summer feeding during periods of drought. Forage crops grown at the station and considered valuable are *Bromus inermis*, Italian rye grass (*Lolium*

italicum), Perennial rye grass (*L. perenne*), reed fescue (*Festuca elatior arundinacea*), English blue grass (*F. pratensis*), orchard grass (*Dactylis glomerata*), Hungarian alfalfa and alfalfa from India and Africa, Japanese barnyard millet, sorghum, Kafir corn, milo maize, and cow-peas. The cultural operations employed with a number of these crops are given, together with notes on the grazing of horses on the Japanese barnyard millet and of feeding sorghum to milch cows. The sorghums were greatly relished by the cows and temporarily increased the milk flow. Feeding the sorghum with alfalfa was found more desirable than feeding either alone. Kafir corn fodder containing fully ripe seed was relished by horses. The leaves and seeds were eaten clean and likewise the upper portions of the stalks. No difference was noticed in the relative growth of brown and white Kafir corn.

The effect of a second irrigation of alfalfa to induce germination was studied. After the first irrigation the plats formed a hard surface crust about $\frac{1}{4}$ in. thick and cracked into large cakes in drying. Some seed germinated and were just showing their seed leaves in the cracks when a portion of the plat received a second irrigation. Plats thus irrigated gave a poorer stand of alfalfa without exception than those irrigated but once. This was due largely to the filling up of the cracks in the crust with sediment and thus smothering many of the young alfalfa plants.

Observations on the loss in the first stages of growth of alfalfa plants due to crowding show that the alfalfa plant is extremely tenacious of life and has great endurance in extremes of drought, there being but few deaths even where the plants were most crowded.

The value of the cowpea as a hay crop and green manure is discussed and some cultural data given on inconclusive experiments in growing this crop at the station.

Results of manuring, C. E. MEAD (*New Mexico Sta. Bul.* 33, pp. 41-43).—Oats were grown on land a part of which had borne a crop of hairy vetch the preceding season. At the time of heading the oats on the vetch portion of the plat averaged about $3\frac{1}{2}$ ft. in height, while the remaining portion of the plat averaged about 2 ft. At harvest the yield on the vetch land was 25 bu. per acre, while the remainder of the plat gave but 18 bu. per acre.

In another experiment oats were grown after field peas, the vines and pods of which had been turned under. The yield of grain from this plat was at the rate of 47 bu. per acre. The yield the preceding season on similar soil not fertilized with pea vines was at the rate of 9.6 bu. per acre.

Other experiments with corn grown on land fertilized with barnyard manure and on new land are reported. The barnyard manure had a good effect on the physical condition of the soil and considerably increased the yield of corn, about the same results being obtained as when corn was grown on new land.

Sugar-beet investigations, J. D. TOWAR (*Michigan Sta. Bul. 179, pp. 93-113, figs. 6*).—These investigations include fertilizer experiments with beets on different soils at the station and in cooperation with farmers in different parts of the State, variety tests, and trials of plantings at different dates.

Subsoiling is shown to be practicable and not so difficult as is usually supposed. Spring subsoiling for beets proved disastrous at the station in 1899, as the ground did not regain a sufficient amount of moisture to support the crop.

In a fertilizer test at the station on sandy soil of medium fertility, cow manure, salt, ashes, lime, hen manure, complete fertilizers, and a commercial brand of sugar-beet fertilizer were used, besides various single elements applied alone and combined in two's. The details of the results obtained are tabulated. On the plats receiving the lime a slightly greater development of leaf was observed than occurred on the unlimed plats. At harvest time an average increased yield of 1,210 lbs. of beets per acre was obtained on the limed plats, while the percentage of sugar remained practically the same. There was a slight decrease in the percentage of purity. In this and other experiments at the station nitrate of soda has proved superior to sulphate of ammonia for sugar beets as regards yield, sugar content, and purity. Beets on plats fertilized with nitrate of soda in this experiment germinated earlier and made a greater development all through the first half of the season than on any of the other plats.

Fertilizer experiments were also conducted on thoroughly subdued and well drained muck land at the station, using nearly all of the fertilizers noted above. During the season the beets seemed to suffer more from drought on this muck soil than on heavier land, while at harvest time they were apparently making stronger growth than at any previous period. It is thought that if the season had been prolonged a month good yields of beets would have been obtained. The highest yield, 23,814 lbs., was obtained on the plat fertilized with unleached wood ashes at the rate of 1 ton per acre. The use of potash regularly resulted in increased yields. An injurious effect seemed to follow the use of phosphoric acid. Applications of a layer of sand proved especially valuable on this soil. The use of lime resulted in decreased yield, and in beets having a low sugar content and purity.

In culture experiments at the station plantings of beets were made weekly from April 22, when the soil temperature was about 50° F., to May 27. There was a decided advantage as regards yield in favor of the earlier plantings, while the sugar content was slightly higher and the percentage of purity averaged 3 per cent higher. The author considers it safe and wise to plant beets as early in the spring as any other farm crop.

In order to determine the effect of fall growth of beets samples

were analyzed at different times. From October 19 to November 1 the sugar content of the beets averaged 14.74 per cent, the purity 82.23, and from November 4 to 23, 13.89 and 81.03 per cent, respectively. It is thought that this decrease in sugar content and purity was more than made up by the increased growth of the beets. On muck soil this increase in growth from October 20 to November 23 amounted to 2,893 lbs. per acre. The analyses of about 460 samples of sugar beets between October 15 and December 1 showed a similar decrease in sugar content and purity as the season advanced.

Seven varieties of sugar beets were grown in 1898 and again in 1899. In 1898 Zehring, Kleinwanzlebener, Vilmorin Improved, Vilmorin Blanche, and Schreiber Élite were the best varieties grown, while in 1899 Zehring, Russian, Rölker EE, and Rölker ZZ gave the most satisfactory results.

The relation of the size of the beet to its sugar content was studied, and some figures are given on the subject. In general the smallest beets were richest in sugar and the largest poorest in this constituent.

In the cooperative experiments beets were grown on sandy soil, sandy loam, and clay loam, and various fertilizers applied alone and in combinations. Data regarding the yield, sugar content, and purity of beets grown on each plat are tabulated. No particularly significant yields were obtained on any of the plats. The best results followed the application of 480 lbs. per acre of a mixture of 120 lbs. of nitrate of soda, 240 lbs. of phosphatic rock, and 120 lbs. of muriate of potash. Relative to the use of nitrate of soda the author states that when used alone it "generally produced beets of a low percentage of sugar, but when used in connection with sufficient amounts of the other 2 elements normal beets are produced."

The yields of beets obtained on clay loam, sandy loam, sand, clay, and muck in the cooperative experiments with farmers in 1897 and 1898 are summarized. The results indicate that "a mixture of equal parts of sand and clay, or varying 10 per cent from equal parts, is a superior sugar-beet soil." Fairly good results were obtained in these experiments on muck soil, a result which it is thought will prove of considerable economic importance to the State because of the abundance of these soils.

Results secured with sugar beets at other stations are noted and illustrations given of diseased roots and roots grown under unfavorable cultural and soil conditions.

Sugar beets in 1898, R. H. McDOWELL and N. E. WILSON (*Nevada Sta. Bul.* 43, pp. 30, map 1, pls. 5, figs. 2). —Cultural experiments with sugar beets are reported in continuation of previous work (E. S. R., 10, p. 631). As a rule 8 irrigations are given sugar beets in Nevada. Eight varieties were grown in 1898. The sugar content of the juice of 25 samples grown at the station and over the State averaged 17.67

per cent, with a purity coefficient of 79.18 per cent. The ripening of 2 crops of beets in one season is reported by a grower in Lincoln County. Suggestions regarding seed, cultural operations, and implements, factory devices for unloading beets rapidly, etc., are included in the bulletin, and a map showing the sugar-beet area of the State. Portions of the State are considered very well adapted to sugar-beet culture.

Sugar beets in 1899, N. E. WILSON and R. H. McDOWELL (*Nevada Sta. Bul. 44, pp. 21, figs. 2*).—In previous years (see above) experiments have been conducted largely for the purpose of making a survey of the State relative to its sugar-beet producing powers. In 1899 the principal attention was given to the possibility of producing beets of a high saccharine content on a commercial scale in those sections which had previously shown most promise. Considerable tabular matter is given, which shows that the average of 183 samples analyzed in 1899 contained 16.2 per cent of sugar in the beet, having a purity of 84.68 per cent.

"The locality giving the best results is the Lovelock Valley, situated in the southeastern part of Humboldt County, on the Humboldt River. The soil in this valley is peculiarly rich and fertile, and has been formed by the growth and decay of tules, which have been covered by sediment, thus forming alternate layer after layer of decayed tule and sedimentary silt to a great depth. In one instance borings have been made to the depth of 480 ft., showing the same formation the entire distance. The soil is free from rocks, and is very friable and porous, thus affording an excellent opportunity for the beet to go down into the soil, resulting in an ideal shape, with no side roots. Many of the beets from this section this year were from 18 to 27 in. in length and in good proportion otherwise. From 20,000 to 30,000 acres of this land could be obtained for beet growing in the advent of a factory for the manufacture of the product."

The factory conditions of a number of other localities are noted, and remarks made on water and limestone for factory use.

On the effects on tobacco of shading and the application of lime, W. C. STURGIS (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 252-261*).—The report is in part a continuation of work previously noted (*E. S. R.*, 11, p. 755). The soil used was a close clay one, packing hard after rains, and similar in character to the East Hartford tobacco lands where the calico disease prevails. The land was laid out in 2 long plats running north and south with a 6-ft. alley between them. The western plat was shaded with a screen of lath, cutting off half of the light and placed about 5 ft. from the ground. Both plats were divided into 4 smaller plats, receiving, in addition to other fertilizers, 300, 500, 1,000, and 2,000 lbs. of air-slaked lime per acre, respectively.

On the unshaded plats which received the heaviest applications of lime the calico disease did not occur, although there were a few rusty leaves. Rusty leaves were also noticed on the shaded plat which received the most lime. On the unshaded plat which received lime at the rate of 500 lbs. per acre 17.5 per cent of the leaves were affected

with calico, while on the corresponding shaded plat only 2.5 per cent were affected. Ten per cent of affected leaves occurred on the unshaded plat given but 300 lbs. of lime and 5 per cent on the corresponding shaded plat. On the whole, the shaded plats contained a smaller percentage of leaves affected with calico than the unshaded. The author considers that the experiments were conducted on too small a scale to form the basis for final judgment.

Another effect, apparently due to shading, was the increased prevalence of the so-called "natural spot." Fully 30 to 40 per cent of the shaded plants were sprinkled with small whitish spots of dead tissue, while not more than 1 or 2 of the unshaded plants showed them.

Relative to the effect of shading on the growth of the plants and the quality of the leaf it was found that the shaded plants grew much slower than the unshaded, and showed the bud lower down and were therefore topped unnecessarily low. After topping the shaded plants filled out and produced unusually large, thin leaves of a very dark color. The unshaded plants were ready for cutting 2 weeks before the shaded plants. The difference in the weight of cured leaves from the shaded and the unshaded plats was quite marked. The average weight of plants from the shaded plats was 0.27 lb. and from the unshaded plats 0.34 lb. The stalks also of the shaded plants were noticeably smaller and lighter than the others, a fact due in great measure, it is thought, to lower topping. The greatest yields from both the shaded and unshaded plats were obtained where the larger amounts of lime were applied.

"The total thickness of the leaf was decreased by shading by over 30 per cent; the upper epidermis by 31 per cent; the palisade layer by 35 per cent; the spongy parenchyma by 27 per cent; the lower epidermis by 14 per cent."

The quality of the finished product was judged by experts.

"The tobacco, on the whole, was pronounced of poor quality; that from the unshaded plats was coarse, with harsh and wiry veins; that from the shaded plats was objected to as having been immature when cut and consequently of very poor color and of so thin and smooth a texture as to be practically worthless. It was noticeable that in the case of both the shaded and the unshaded tobacco the plats which received the largest quantity of lime showed a good deal of 'white vein.' The best of the unshaded tobacco was adjudged to be that which had received lime at the rate of 1,000 lbs. per acre. The best of the shaded tobacco was that which received lime at the rate of 2,000 lbs. per acre. On the whole, the shaded tobacco was pronounced far inferior to the unshaded. This latter opinion did not prove to be shared universally; one expert buyer, who knew nothing of the history of the tobacco, pronounced in favor of the shaded tobacco, both as regards texture and quality. . . .

"No difference could be observed, as regards the character of the ash, between the tobacco which had the least amount of lime and that which had the most; in both cases the ash was grey, flaky, and deficient in firmness. The burn of the tobacco from all the plats was equally poor."

The results of the experiment suggest "that the use of lime may not, in all cases, exercise the deleterious effect on tobacco that some grow-

ers suppose it to, and that there is some reason for thinking that its use may tend to decrease the prevalence of calico."

Experiments in curing and in fermenting wrapper leaf tobacco, season of 1899, E. H. JENKINS (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 286-297*).—These experiments in curing tobacco in a barn provided with hot-air flues and in fermenting Connecticut tobacco in bulk are similar in character to those carried on by the station in 1898 (E. S. R., 11, p. 730). The curing barn is again described and some data are given on outside and inside temperatures of the barn on different days and at different times during the night. The night temperature of the air inside the barn is usually much warmer than the outside temperature, while the reverse is frequently true in the daytime. The general method in controlling the curing is to open the barn wide on clear bright days and air it thoroughly. As soon as the outside temperature falls to that of the inside, the barn is closed except under the sills and in the ridge; the fires are started and run through the night. "The object was to assist the upward air current which naturally moves at night and to keep the tobacco from the night chill, thus making the temperature of the curing much more nearly uniform." Curing under these conditions in 1899 was much more rapid than where no artificial heat was used and proved valuable as a means of controlling the pole burn. The system of heating adopted is not entirely satisfactory as certain dead-air spaces occur which favor the development of pole burn. The experiments in curing are to be continued.

Some observations on the temperature of tobacco fermented in cases were made during the spring and summer of 1899. The cases held about 300 lbs. and were piled in an unheated storehouse, as is customary in Connecticut. Weekly readings for 4 cases from March 4 to August 5 taken with telephone thermometers are recorded. Some of the tobacco lay 9 weeks after the experiment began before reaching a temperature of 70° F. It is believed "the greatest danger to cased tobacco from mold and mustiness is when it lies cool, damp, and unfermented, waiting for sufficient heat from the air to penetrate it and start the fermentation."

The experiments in fermenting Connecticut tobacco in bulk noted in 1898 (E. S. R., 11, p. 730) were repeated in 1899 in cooperation with the Division of Soils of this Department. The bulk was built up on a slightly raised platform 12 ft. long and 5 ft. wide, with vertical headers of boards at each end. A layer of hot trash tobacco, which had been sprayed with warm water and allowed to ferment for 4 days, when it reached a temperature of 131° F., was first put down and then alternated with layers of first wrappers, butts on the outside, the tips toward the center. No pressure was applied. The hands of tobacco were simply laid on the pile. Number 2 wrappers, which were too dry to ferment, "were brought into 'case' by dipping the butts about 2 in.

deep into warm water and then holding the hands by their butts and shaking them vigorously until the water was well distributed." They were piled on the bulk without layers of trash. The whole bulk weighed about 5,500 lbs. It was covered with trash, woolen blankets and rubber blankets. The temperature of the room was maintained at from 80 to 85° F. and the humidity such that a hand of unfermented tobacco hung in the room remained pliable.

Five days after the bulk was built, the temperature near the bottom of the pile had reached 115° F., while near the top it was 121° F. At this point the bulk was torn down and the leaves shaken out a little and the pile rebuilt. Between December 23 and January 1 the temperature in different parts of the pile ranged from 110 to 118° F. The bulk was again rebuilt, and the highest temperature reached during the next 23 days was 113° F. (near the top), while near the bottom of the bulk the highest temperature reached was only 91° F. Examination of the leaf during the latter part of January showed that the gum was gone and the whole body of the leaf thoroughly fermented. Later the fermented tobacco was examined by experts.

"The unanimous opinion of all these gentlemen was that the [fermentation] process was a remarkably successful one. The leaf was of a perfectly even color from the tip to the stem end.

"The gum was all gone, the leaf was light and elastic, and there had not been the slightest damage during the fermentation. Particular attention was given to the leaves on which the butts of the next layer of leaves rested, as the dealers thought that there some damage must have been done. Careful search was made, but not a single damaged leaf could be found in the bulk. Another point was that of water stain. As stated above, all the hands—except those of first wrappers—had their butts dipped in warm water and the leaves shaken out, immediately before putting into the fermenting room. A few of the second wrappers came out of the fermentation with some water stain near the midrib of the leaf, but none on the margin, but the most of the dipped leaves showed no traces of water stain. The second wrappers were dipped just at nightfall and in great haste and probably not sufficient care was taken in shaking them out. If they had been left a few days longer in the first bulk, probably there would have been no water stain, even in the overwet leaves.

"Our experience has shown that unfermented leaf will bear a good deal of wetting if it is warm and goes at once into active fermentation. But under no other circumstances will it bear wetting."

By comparing the weights of the fermented and unfermented leaf, it was found that a quantity of tobacco weighing 3,076 lbs. before casing and fermenting in bulk was decreased in weight only 8 lbs. after fermenting and 3 of the grades of tobacco fermented were damper at the end of the process than before they were dampened at the beginning of it. The fermented tobacco dried out somewhat rapidly in the cases.

Physiological studies on Connecticut leaf tobacco, O. LOEW (*U. S. Dept. Agr., Rpt. 65, pp. 57*).—A report is given on some physiological investigations of tobacco. The work deals with a number of

questions relating to the physiology of the leaf and the chemico-physiological changes which take place in processes of curing and sweating.

The acidity in the plant was greater in the morning than in the evening. "The custom of harvesting tobacco on bright sunny days has, therefore, a sound physiological foundation." The upper leaves contain more acid than the lower leaves. The acidity of the lamina decreased as the process of curing in the plant proceeded.

The presence of diastase in tobacco leaves was determined by the author, as was also a proteolytic enzyme. The latter differs from the ordinary trypsin in that it can not attack fibrin and casein under ordinary conditions, while it can attack dissolved albumen. The presence of a cellulose-dissolving enzyme (cytase) in tobacco leaves was not determined with certainty. In tests with oxidase and peroxidase both seemed to have the main character of albumoses. Oxidase in the juice of the tobacco leaf diluted with about 20 parts of water was killed by heating to 66 to 67° C. for 3 minutes. The presence of certain alkalies increases the resistance of oxidase to heat, while acids decrease it. Peroxidase in an alcoholic mixture was killed at the temperature of 70° C., while in a mixture of ammonium sulphate the enzyme was not killed after heating for a short time to 93° C.

Since manganese has been found as a regular ash constituent of the oxidases, it was thought desirable to see what would be the influence of fertilizing tobacco with solutions containing manganese. A 0.1 per mille solution of sulphate of manganese was used to water some tobacco plants until each had received 0.6 gm. of that salt. Examination of the ripe leaf showed no noticeable increase of oxidase or peroxidase in the plants so treated.

A third oxidizing enzyme in the tobacco plant, to which the name catalase is given, was observed. It occurred in the unfiltered juice of fresh tobacco leaves.

"This enzyme is killed at 72 to 75° C. (161 to 167° F.). It is an oxidizing enzyme, [but] it differs essentially from the ordinary oxidase and peroxidase.

"This enzyme is the most durable of those in the tobacco leaf under ordinary circumstances, since it occurs in tobacco even over 6 years old, in which no trace of other enzymes, not even of the peroxidase, can be found.

"It is certainly an important factor in the heating up of the tobacco pile, as recent experiments with fermenting tobacco have shown.

"The general occurrence of this enzyme in plant as well as in animal cells suffices to indicate a highly important physiological rôle. It is probably intimately connected with the process of respiration. The following two hypotheses as to its function appear the most probable to the writer: (1) Since many oxidative processes lead to the formation of hydrogen peroxid as a by-product, it is important that such a poisonous by-product be at once destroyed when accidentally formed in the cells in the course of the respiratory oxidations. (2) This enzyme may have the office of loosening affinities in fatty acids and sugar in order not to tax the chemical energy of the protoplasm itself too heavily when these compounds are consumed for the purpose of respiration."

The mosaic disease of the tobacco plant is discussed in considerable detail, some figures being given to show the decreased malic-acid content of the pith, midrib, and lamina of the leaves of diseased over healthy plants.

Tests for oxidase in fresh-cured and fermented tobacco are given in detail, and some results obtained in testing for these enzymes in different tobaccos are reported. Methods of testing for catalase and the results obtained with various tobaccos, as well as of cigars of commerce, are also recorded. The "grain" of tobacco was found to be formed during the curing process.

Other subjects discussed in this bulletin are the contents of the tobacco leaf, ripening, behavior of the oxidizing enzymes in the curing process, development of the brown color in curing tobacco, chromogens of tobacco, sunburn of tobacco leaves, "white veins," "salt-peter" on tobacco, bacterial hypothesis of sweating tobacco, sweating musty tobaccos, aroma of tobaccos, nitrite content in sweated tobaccos, and the amount of heat produced by sweating in bulk.

Report on field experiments 1899, D. A. GILCHRIST (*Jour. Univ. Extension Col., Reading [England]*, Sup. 9, 1900, pp. 7-47, 52-54, 59-68).—The experiments here recorded were made at a number of different centers. The data given cover the results obtained in fertilizer tests for meadow lands and pastures, oats, mangels, swedes, and potatoes; the use of various seed mixtures for hay and pasture; tests of varieties of oats; and rotation experiments. Suggestions for the manuring of various crops are added.

Kentucky forage plants—the grasses; analyses of some Kentucky grasses, H. GARMAN and A. M. PETER (*Kentucky Sta. Bul. 87*, pp. 55-122, pls. 14).—In part 1 of this publication notes are given on 141 species of native and introduced Kentucky grasses. Many of the grasses have been grown for a number of years on experimental plats at the station and their comparative values noted. Considerable data on the appearance, growth habit, and value as forage crops of the more important species are recorded, including some statistics on the State production of corn and wheat.

Part 2 gives the results of analyses with reference to food constituents of the air-dry and water-free material of 79 samples of grasses cut at different stages of growth and comprising 31 species. Analyses of the hay and seed are frequently included.

Drought-resisting forage plants at the cooperative range experiment station, Highmore, S. Dak., J. H. SHEPARD and D. A. SAUNDERS (*South Dakota Sta. Bul. 66*, pp. 35-52).—The data here given with the different forage plants have been reported by the Division of Agrostology of this Department (*E. S. R.*, 12, p. 332). The mechanical and chemical analyses of the soils of Highmore are added.

Analyses of sugar cane and sugar beets, A. M. PETER (*Kentucky Sta. Rpt. 1898*, pp. XVII-XXI).—Tabulated results of analyses with reference to sugar content of 8 samples of sorghum and 105 samples of sugar beets.

The area of leaf surface on the topped tobacco plant, E. H. JENKINS (*Connecticut State Sta. Rpt. 1899*, pt. 3, p. 297).—This was determined by stripping off the leaves from the topped tobacco plant, carefully tracing the outlines of each leaf on rectangular sheets of paper whose area and weight were known and then cutting out the traced leaves with scissors. By weighing the leaf figures and cuttings separately it was calculated that the 18 leaves taken from the topped tobacco plant investigated had an area of 27.2 sq. ft. "Reckoning 7,700 plants to the acre it would

appear that the leaves from 1 acre of Connecticut Habana tobacco at harvest time would cover 4.8 acres."

Bacteria for lupines—inoculation tests with soil, C. SCHREIBER (*Rev. Gen. Agron.*, 9 (1900), No. 7, pp. 302-304).—The use of 6,000 kg. per hectare of soil from an old lupine field resulted in an increase of yield of lupines grown on uninfected soil from 17,600 kg. per hectare where no inoculating soil was used to 40,100 kg. per hectare.

The effect of quicklime on the root bacteria of legumes, SALFELD (*Deut. Landw. Presse*, 27 (1900), No. 75, p. 932).—The author's experiments with quicklime on poor sandy soil in 1894 led him to the conclusion that it was harmful to the growth of root tubercles on field peas, lentils, garden peas, and *Lathyrus clymenum* (E. S. R., 6, p. 533). Later field and pot experiments have shown that the poor results obtained in 1894 on the limed plats must have been due to some other cause, since the legumes have been grown with 3 times as much quicklime applied per acre and the bacteria in nowise hindered in their action. On the other hand, the presence of the lime seemed to permit of their greater development.

HORTICULTURE.

Fruits, vegetables, flowers, and ornamental shrubs at the Experimental Farms in Canada, W. T. MACOUN, W. S. BLAIR, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts.* 1899, pp. 73-94, 100-104, 109-112, 123-127, 259-281, 315-334, 362-383, 411-424, figs. 12).—Separate reports are here given for tests of large numbers of varieties of vegetables and orchard and small fruits. At the central station in Ottawa, and at each of the branch stations in the Maritime Provinces, Manitoba, Northwest Territories, and British Columbia, lists of seeds and cuttings distributed by the stations, and of the vegetables recommended to farmers are given, together with notes on the character and adaptability of various fruits, flowers, and shrubs to their respective localities. The report of the horticulturist, W. T. Macoun, at the Central Station includes an account by two farmers of the successful growing and fruiting of apples, plums, cherries, pears, and small fruits in high latitudes ($48^{\circ} 26''$), where temperature variations ranged between -40° and $+104^{\circ}$ F. The secret of success in these regions seems to lie largely in removing the snow from the roots of the trees during the winter so that the ground will freeze to a depth of 4 or 5 in., after which snow and straw may be placed at the base of the trees in order to prevent alternate thawing and freezing before fine weather comes in the spring. Many varieties of apples do not succeed in Ottawa. They are subject either to sun scald, root killing, or killing of the terminal branches. Experiments in top grafting to overcome these obstacles are being conducted. Experiments in spraying plums, cherries, and apples with whitewash in winter to retard the blossoming period in spring are reported at the same station. The retarding of the swelling of the buds was quite marked with plums and cherries, but the difference in dates of bloom-

ing was very slight. A considerable number of the blossoms of the plum were killed by the whitewash. The whitewash appeared to have but little effect in retarding the swelling of the apple buds. A record of the relative dates of blossoming of the different varieties of apples at the Central Station is given.

Roses at the Maritime Experiment Farm have been successfully protected during the winter by placing barrels with the heads knocked out over the base of the bushes and packing with various materials, one of the most satisfactory of which was clean straw. Notes on the culture and dates of blooming of 58 varieties of hardy flowers are recorded, as is also data for an experiment on the effect of removing the suckers from the base of sweet corn in the production of ears. No conclusive results were obtained. Soaking sweet-corn seed 24 hours in warm water before planting proved of no value.

On the use of commercial fertilizers for forcing-house crops, E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 219-235, plan 1*).—The work here reported was begun in 1894, and the results secured up to 1897 have been published (E. S. R., 10, p. 246).

Tomatoes (pp. 219-224).—Previous experiments with this crop have shown that larger crops of tomatoes, normal in size, color, taste, and chemical composition, could be grown in a soil of coal ashes and peat moss by the aid of commercial fertilizers than in a rich compost with or without commercial fertilizers. Experiments in 1898 showed that 28 oz. of nitrogen, 6 of phosphoric acid, and 21 of potash applied to each 100 sq. ft. of bench space of coal ashes and peat moss was excessive and injured the plant. Lorillard proved superior to either Acme or Essex Hybrid for forcing.

In 1899 soils of compost and of coal ashes and peat were placed in alternate plats throughout the forcing house and 2 crops of Lorillard tomatoes grown. Three plats were filled with compost which had been "sterilized" by heating 1 hour with steam. Nitrogen was furnished to the different plats in the form of nitrate of soda, cotton-seed meal, and fine bone, respectively.

"There was practically no difference in the average yields from plats dressed with nitrogen in nitrate of soda, cotton-seed meal, or ground bone. The yield from plats dressed with bone was slightly below the others. The soil of coal ashes and peat on the average yielded more tomatoes than the compost.

"Sterilizing the compost by heating for 1 hour with steam caused it to produce a heavier growth of plant and a smaller yield of fruit. A poor subsoil which was used in the benches, whether fertilized with chemicals or not, produced only about $\frac{1}{3}$ as much weight of tomatoes as the compost. Sutton Best of All gave a slightly larger yield than Lorillard as well as fewer and heavier fruits per plant. It was somewhat later in blossoming and maturing fruit. It does not appear to be greatly superior to Lorillard as a forcing variety."

The pollination of tomatoes in this experiment was secured by hold-

ing a spoon or ladle under each blossom and tapping the flower lightly from above. The jarring of the flower shakes the pollen into the spoon and brings the stigma into contact with it, pollination thus being secured. A new method was tested in 1899. The corolla of the flower was pulled away after it had fully opened.

[In doing this] "the anthers are broken open and the pollen, if ripe and dry, escapes into the air and some usually reaches the pistil of the flower and fertilizes it. . . . Blossoms pollinated in this manner produced as many fruits as where the spoon method was used. . . . The spoon method, however, took less time and it seems more likely to effect cross-fertilization."

Lettuce (pp. 224-226).—Results obtained subsequent to 1896 have been reported (E. S. R., 8, p. 405). The plats in the forcing house were $5\frac{3}{4}$ in. deep and contained 14.5 sq. ft. of surface each. Ten plats were filled with a rich compost of rotted turf and horse manure, and 10 with coal ashes sifted through a sieve with 4 meshes to the inch. The coal ashes were mixed with 5 per cent peat moss passed through the same sieve. During the season 3 crops of White Tennis Ball lettuce were grown on each of the plats. The yield of lettuce was smaller on sub-watered than on surface-watered plats with both kinds of soil. With the mixture of coal ashes and peat moss, applications of 162.9 gm. of nitrate of soda, 49 gm. of dissolved boneblack, and 88.8 gm. of muriate of potash gave as good results as larger amounts of these ingredients.

"The yield from plats of coal ashes alone was decidedly less than from the mixture of ashes and peat moss. From the compost soils to which only small quantities of nitrate were added no larger yields were got than from the corresponding ashes and peat plats, but when to the compost were added the same amounts of fertilizers as to the ashes and peat, the yields were larger from the compost. In all cases more marketable heads were got from the compost plats."

The following year mixtures of from 9 to 12 per cent of peat moss with coal ashes proved a better soil medium for lettuce than mixtures containing less than these amounts. In soil containing 12 per cent of peat moss, 1,000 plants, roots and heads, removed 443 gm. of nitrogen, equivalent to $6\frac{1}{2}$ lbs. of nitrate of soda; 185 gm. of phosphoric acid, equivalent to 3 lbs. of dissolved boneblack, and 697 gm. of potash, equivalent to $3\frac{1}{16}$ lbs. of muriate of potash.

In 1898 a black swamp muck of the neighborhood, which contained no fiber, proved inferior to peat moss as a soil medium for lettuce.

"A number of comparisons were made of the growth of lettuce on rich compost and of its growth on the same kind of compost which had been sterilized by heating it for 1 hour with live steam, which raises the temperature of the soil to above 100° C. . . . In every case a better crop was grown on sterilized soil than on the corresponding plats untreated. Lettuce transplanted only once was much larger and heavier than that which was twice transplanted. Fertilizer chemicals depressed the yield in each case, while the addition of lime did not greatly affect the weight or quality of the crop."

Carnations (pp. 226-235).—For a previous report see E. S. R., 10, p. 245.

"In the season of 1897-98 the largest number of blooms per plant was produced on rich compost to which nitrate of soda, dissolved boneblack, and muriate of potash had been applied at the rate of 620 gm., 154 gm., and 422 gm., respectively, per 100 sq. ft. of bench space, while the compost without fertilizers gave a slightly smaller yield of blooms than the soils made of coal ashes with 3 per cent of peat, to which were added 1,240 gm. of nitrate of soda, 462 gm. of dissolved boneblack, and 844 gm. of muriate of potash per 100 sq. ft. of bench space."

In 1899, 7 carnation plats were filled with a mixture of 184 lbs. of bituminous coal ashes and 5½ lbs. of peat moss, 3 with compost, and 2 with compost sterilized by heating for 60 minutes in steam. All the plats filled with ashes and peat and one of the compost plats were fertilized with various amounts of nitrogen in the form of nitrate of soda, cotton-seed meal, or bone dust, phosphoric acid in the form of dissolved boneblack, and potash in the form of muriate. The varieties Day Break, Thomas Cartledge, and Lizzie McGowan were used in the test.

"The 4 plats which contained the mixture of coal ashes, peat, and commercial fertilizers yielded a larger number of blooms, a greater weight of blooms, and blooms of somewhat larger size, on the average, than the 2 plats which contained rich unsterilized compost.

"Plat 183, of sterilized compost, yielded more blooms than any other in the experiment, though the average weight of blooms was not as great as of those grown in the coal ashes and peat moss. The other plat of sterilized soil, No. 185, gave a very small yield. We believe this is explained by the fact that, through an oversight of the attendant, it was omitted in the watering on a bright day and the plants were badly wilted. This plat yielded less than any other.

"The comparison of the different forms of nitrogenous fertilizer indicates that fairly good results may be obtained with either nitrate of soda, cotton-seed meal, or bone. Plat 178, to which bone was added, yielded a larger number of blooms than any other. The blooms on the average were not larger than those from plats where nitrate or cotton-seed meal was used. The nitrate plats produced blossoms having a greater average weight, diameter, and length of stem than those from plats where other forms of nitrogen were used."

Representative blooms from different plats were analyzed, and from the results the amounts of fertilizing materials removed were calculated.

Tomatoes, F. S. EARLE (*Alabama College Sta. Bul. 108, pp. 36, figs. 2*).—The author purposes to give in this bulletin an outline of the methods employed by the best commercial tomato growers in the latitude of the station. The topics discussed include soils and fertilizers, plant growing, cultivation and training, pruning, diseases and insects, varieties, and marketing. Some results obtained in tomato growing at the station are included under the different headings. The diseases are noted elsewhere.

An account is given of growing Irish potatoes, peppers, eggplants, and tomatoes on plats fertilized alike as regards acid phosphate and cotton-seed meal. Two of the plats received in addition kainit at the rate of 1,500 lbs. per acre, 2 lime at the same rate, 2 were used as checks, and 2 others had Bordeaux mixture poured along the furrows.

The object of the experiment was to prevent the bacterial wilt. This was not present, but the Sclerotium wilt, black rot, and Alternaria leaf blight were more or less prevalent. The effects of the different treatments are noted in some detail. The Bordeaux mixture largely prevented the Alternaria leaf blight. The Sclerotium wilt was especially abundant on the potatoes where kainit had been used, a decreased yield of 60 per cent occurring on these plats. Tomatoes on the kainit plats were remarkably healthy, and their longevity considerably prolonged.

Lemon Blush has been one of the most satisfactory varieties of tomatoes grown at the station for midsummer and fall crops, and is recommended for home use. In planting for the market it is recommended that 4 or 5 of the best kinds of tomatoes be planted rather than to rely on any one variety alone.

Watermelons and muskmelons in South Dakota, N. E. HANSEN and W. S. THORNER (*South Dakota Sta. Bul. 67, pp. 55-102, pls. 7*).—Results are here reported in tables and descriptive notes of tests of a large number of varieties of foreign and American watermelons and muskmelons during the years 1898 and 1899. Most of the foreign melons were of Russian and Asia Minor origin. The results of the tests show that the American muskmelons are much better adapted to the locality of the station than any of the foreign varieties tested. The smaller varieties proved earlier than the larger ones and are therefore preferred for localities where the growing season is short. From the standpoint of productiveness and quality Jenny Lind was the best variety grown. Larger earlier sorts were Earliest Ripe, Extra Early Citron, and Nectar of Angels. Other smaller varieties which were both productive and of excellent quality as well as early are as follows: Emerald Gem, Prolific Nutmeg, Newport, Rockyford, Burpee Netted Gem, Round Netted Gem, and Shipper Delight. Large varieties which were both productive and of excellent quality but late were Early Bristol, N. K. and Co. California Cream, and Chicago Market.

Of the 52 foreign watermelons tested, only 1 was found superior in earliness to the 106 American varieties grown. From the earliest watermelon of this variety pure seed was selected and sown. By continued selection it is hoped to increase the earliness of this variety. American varieties ripe September 6 were Light Green Rind Icing, Pride of Georgia, Russian Menmonite No. 7, Peerless, U. S. Dept. Agr. No. 23, Salzer Fourth of July, and Phinney Early Oval. Varieties ripe September 13 were Vick Early, Ruby Gold, Green and Gold, Phinney Improved, U. S. Dept. Agr. Nos. 72, 18, 92, and 88, Mountain Sweet, Black Diamond, Fordhook Early, Wisconsin Hybrid, Extra Early, and Jones.

A few varieties of citrons were grown as well as the orange melon and vegetable pomegranate. Suggestions regarding the preparation and use of the latter are given.

The apple orchard, J. C. WHITTEN (*Missouri Sta. Bul. 49, pp. 21, figs. 6*).—For the past 5 years, experimental orchard work has been under way at the station along several lines.

Previous preparation of the soil (pp. 3-7).—In 1895 young apple trees were planted on old, well-tilled heavy clay loam. Before planting, half the orchard was plowed deep and subsoiled while the other half was simply plowed deep. Subsequent cultivation was the same on both halves. No difference was noticed in the growth of the trees on the two portions of the orchard or in the subsequent condition of the land, and the amount of washing seemed to be about the same on both halves. The author states that while subsoiling may be beneficial on some soils, on soils similar to those noted only deep thorough plowing is necessary.

A young orchard was planted on newly cleared timber land. The location was a steep rocky bluff. Strips 6 or 7 ft. wide were plowed for the trees. The remainder of the land was left undisturbed to prevent washing. The trees planted on the land thus prepared made an excellent growth; the apple roots followed the decaying timber roots down among the rocks and the natural woods' mold and the sprouts which were left to decay formed an excellent mulch to prevent the soil from washing. The author considers this land, which is too rocky and steep for ordinary cultivation, an ideal place for an orchard. It requires much less cultivation than land that has long been tilled and thoroughly subdued. In clearing such lands for orchards, the author advocates the cutting of the trees as near the ground as possible to facilitate cultivation.

When orchards are planted on the hard-pan lands of the State, the hard pan may be loosened by exploding a small charge of dynamite in the bottom of each tree hole. This method, however, is expensive. It is recommended, therefore, to prepare the soil by previous cropping with clover or cowpeas.

The relation of cultivation to the development and growth of apple trees (pp. 7-15).—This subject has been studied for a period of 5 years. "Measurements have been taken of the average annual growth of trees receiving good cultivation, of those receiving partial cultivation, of those in clover and some in blue grass sod. In taking these measurements, a strenuous effort has been made to truly represent the average growth of trees under these various conditions of culture. Measurements have been confined to the leading branches of normal trees. Where trees have suffered from blight, accident, or other conditions unusual to other trees in the same orchard, they have been

rejected. Wherever pruning has abnormally affected the growth, such trees have not been considered. Measurements were made of all the leading branches on about 600 trees, through four seasons' growth." The observations have been made on Ben Davis, Jonathan, Jenet, and miscellaneous varieties of apples. The rainfall for the growing season of each of the years 1894 to 1898 inclusive is also given. Tabular results of the measurements show that the greatest growth has been made by those orchards that have been cultivated most, and that "cultivated trees make a more uniform growth than trees not cultivated." The more the trees are cultivated the less they are affected by drought. This is considered the most important point in the cultivation of orchard fruits in Missouri.

"The unfavorable effects of drought on uncultivated trees are more apparent the succeeding season than they are during the dry year itself. A marked falling off in height growth, and a generally devitalized condition of the trees, may be looked for, in uncultivated orchards, for a year or two following an excessive autumn drought.

"During 1898 more trees died as a result of the previous dry autumn than died during 1897. The unfavorable effects of this drought are yet (1899) apparent in uncultivated orchards." . . .

"During a dry summer and autumn, the orchard soil should be kept in good tilth until the crop of fruit and the wood growth are mature, or until rains come.

"During a wet summer and autumn, cultivation should cease early enough (August first) for the growth to be checked and the wood ripened for winter.

"Failure of the wood to mature in autumn may be as often due to ceasing cultivation too early as it is to continuing cultivation too late. This is particularly true when trees are loaded with fruit."

Crops to be grown in orchards (pp. 15-19).—The value of small fruits, garden vegetables, cowpeas, soja beans, clover, rye, and buckwheat is discussed. It is stated that nothing should be grown in the orchard which will prevent the cultivation of the tree rows. On steep hillsides clover is considered an especially desirable crop to grow to prevent washing. It should be sown in strips running across the hillsides between the rows and the trees given clean cultivation until they are well established.

Cultural methods—implements (pp. 20, 21).—The value of different cultural methods in the orchard is considered. Relative to the culture of other orchard fruits the author states that peaches should be given the same attention as apples.

"Standard pears and cherries usually succeed best if the land is cultivated until they reach bearing age, and then seeded to clover. Dwarf pears should be given the best of cultivation. Plums do best under clean cultivation, but the Americans will succeed fairly well in clover or even in blue-grass pasture. Japanese plums should be treated about the same as the peach."

A chemical study of the apple and its products, C. A. BROWNE, JR. (*Pennsylvania Dept. Agr. Bul. 58, pp. 46; Rpt. 1899, pp. 534-572*).—The following analyses of 25 varieties of apples represent only sound, ripe fruit which, except the summer apples, had been stored in

a cool cellar from 1 to 2 months after picking, to insure the conversion of the residual starch into sugar:

Composition of the apple.

Variety.	Season.	Number of apples.	Water.	Solids.	Invert sugar.	Sucrose.	Total sugar.	Total sugar after inversion.	Free malic acid.	Ash.	Sugar coefficient.

The following table gives the results of the analysis of the ash of the apple:

Composition of the ash of apple.

Constituents.	Per cent.	Constituents.	Per cent.
Potassium carbonate (K_2CO_3)	67.85	Magnesium oxid (MgO)	0.59
Potassium phosphate (K_3PO_4)	14.55	Ferric oxid (Fe_2O_3)95
Sodium chlorid ($NaCl$)60	Aluminum oxid (Al_2O_3)80
Calcium sulphate ($CaSO_4$)	4.52	Silica (SiO_2)40
Calcium oxid (CaO)	2.57		
Magnesium phosphate ($Mg_3P_2O_8$)	6.97	Total	99.80

"While the above analysis shows that the ashes of apples contain a considerable quantity of carbonate of potassium and a small amount of the oxids of calcium and magnesium, the statement should be made that these compounds do not exist in the fruit itself, inasmuch as the reaction of the latter is uniformly acid. The various bases which appear in the above analysis as oxids and carbonates exist in the apple, for the most part, in combination with malic acid as malates."

The chemistry of the growth of the apple is discussed, and the following table is appended, showing the analysis of the Baldwin apple at different periods of growth:

Composition of a Baldwin apple at different periods of growth.

Date.	Condition.	Water.	Solids.	Invert sugar.	Su- crose.	Total sugar.	Total sugar after inver- sion.	Starch	Free malic acid.	Ash.	Sugar coeffi- cient.

For a guide in afterripening and storing, the author advises following the rules laid down by Thomas, which are, in effect, to keep a uniform temperature as near the freezing point as practicable and exclude air currents and bad odors.

The first result of afterripening is the conversion of the residual starch of the apple into sugar, at the conclusion of which the apple may be said to be chemically ripe. The sugar content is now at its highest. A table shows the later changes taking place in the Sweet Vandevere apple in afterripening.

The most notable change is the inversion of the sucrose.

The depletion of the soil by removing a crop of apples and the amounts of fertilizing ingredients stored up in the trees are discussed.

Under the head of apple products, a number of original analyses are presented, and the author discusses the disposal of the large residuum of unmarketable fruit. Attention is called to the importance of the evaporating industry. A table of best varieties for evaporating is listed, methods outlined, and the chemical composition of product given. A popular treatise is given on cider making, together with directions for the proper fermentation and racking. European and American methods are compared and tables shown of fermented and unfermented juices. The manufacture of cider jelly and its chemical composition are described. An analysis of adulterated apple jelly is presented and attention called to the amount of fictitious fruit jellies on the market. Glucose is the most common adulterant.

The method of making and the chemical composition of apple butter is treated. Attention is called to the danger arising from boiling this product in copper or brass kettles.

In the discussion of apple pomace, the author calls attention to the low value of this product as fuel, fertilizer, or food. It has some value in each of the above uses, but it is far more profitable to add small amounts of water to it and repress, using the juice obtained for jelly or vinegar. The chemical composition of first and second pressings is tabulated.

An outline is given of the manufacture of vinegar both by the slow and the quick fermentation processes. The product of the latter process is apt to be more uniform, though the former possesses the finer flavor and aroma. Tables of analyses are presented of pure cider vinegar completely and incompletely fermented. The latter contains alcohol. The adulteration of vinegars is shown, with tables of analyses of the same. The most common adulterants are caramel, molasses, sugar, glucose, and cider jelly. The presence of adulterants can usually be determined by polarized light. The methods of analysis are explained and the results amplified by tables.

Plums—a comparison of varieties, W. J. GREEN (*Ohio Sta. Bul.* 113, pp. 151-163, figs. 13).—The station plum orchard was started in 1893. Up to the present time about 175 varieties have been planted and nearly one-half of these bore fruit in 1899. The different varieties are classified into groups, the characteristics of the groups noted, and the varieties under each group which have been grown at the station are characterized. Native plums are divided into several groups. It is said of them that as a whole they are less injured by the curculio, are not so liable to rot, and are hardier than the European varieties. They are infertile when planted alone, and where a few varieties are planted care should be taken to select varieties which bloom at about the same time in order to insure fertilization of the blossoms. The following are considered the best varieties among the several groups: *American group*—American Eagle, Champion, Hawkeye, Illinois, Ironclad, Louisa, Rollingsstone, and Weaver. *Miner group*—Forest Rose, Miner, Prairie Flower. *Wild Goose group*—Choptank, Milton, Poole Pride, Wild Goose, Whitaker. *Wayland group*—Golden Beauty, Reed, Sucker State, Wayland, Moreman. *Chickasaw group*—Newman, Pottawattamie, Yellow Transparent. *Triflora group, or Japanese plums*—Abundance, Chabot, Burbank, Ogon, Red June. *Domestica group*—Arch Duke, Bradshaw, Coe, Golden Drop, Grand Duke, German Prune, Gueii, Imperial Gage, Lincoln, Prince of Wales, Reine Claude de Bavay, Yellow Egg. *Hybrid plum*—Gold and Juicy.

An observation of the effects of nitrogenous fertilizers on California privet, W. E. BRITTON (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 217, 218, fig. 1).—In connection with the propagation of California privet (*Ligustrum ovalifolium*) for use as a hedge, observations were made on the effect of nitrogen in the form of nitrate, cotton-seed meal, and ground bone. The privet was grown in 5-in. pots of sandy soil, practically free from humus, to which 1 gm. of carbonate of lime, 0.8 gm. of dissolved boneblack, and 0.4 gm. of muriate of potash were added. To a part of the pots 0.2 gm. of nitrogen was used in the form of sodium nitrate, cotton-seed meal, or fine, hard, raw bone. Others received no nitrogen. "The plants in soil to which nitrate had been added were much larger than any others and the foliage was of a darker

green color. Those in soil to which cotton-seed meal was applied made only a fair growth, while the effect of the bone fertilizer was scarcely apparent." At the end of the experiment the check plants measured from 7 to 10 in. high; plants fertilized with nitrate of soda, 24 to 30 in. high; with cotton-seed meal, 15 to 16 in. high, and with fine raw bone, 9 to 10 in. high.

Note regarding the effect of the winter upon chestnut grafts and scions, W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, p. 239*).—Chestnuts grafted at the station in 1898 (E. S. R., 11, p. 742) were examined during the summer of 1899. The early set scions that had made the largest growth were found to be least injured by the winter. Scions set later than June 15 were all dead.

"One scion set May 6, which made a growth of over 6 ft. in 1898, lived through the winter and made a total growth of over 21 ft. in 1899. Others set the same day and which grew well in 1898, also made a good growth in 1899 and were then killed, presumably by the extreme drought which prevailed through the latter part of the season. So that with the combined effect of winter and drought, the percentages of scions set in 1898 and now alive is very small."

The scions set in 1899, although apparently healthy, appeared to have been injured by the winter. Others started and were killed by drought. But few were alive at the end of the season.

The report of the horticulturist, L. C. CORBETT (*West Virginia Sta. Rpt. 1899, pp. 36-45, figs. 5*).—An outline is given of the work of this department in hand and of that contemplated. A detailed account, with illustrations, is given of an improved auxanometer and a transpiration apparatus, with some explanations as to the uses of these instruments in studies of plant physiology.

The cultivation of horse radish (*Queensland Agr. Jour., 7 (1900), No. 3, p. 233*).—Methods of culture observed in Bohemia are given.

Canning corn and vegetables, R. H. PRICE (*Farm and Ranch, 19 (1900), No. 42, pp. 10, 11*).—Some of the advantages of running a cannery in connection with truck gardening operations in Texas are noted and data given showing the cost involved.

The propagation of high-grade fruit, G. E. POWELL (*Ontario Fruit Grower's Assoc. Rpt. 1899, pp. 32-47*).—A popular article dealing especially with the propagation of the apple and the use of crimson clover as a cover crop for the apple orchard.

Observations on the fertilization of peach orchards, E. H. JENKINS (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 283-285*).—A report of progress on experiments in fertilizing Mountain Rose, Champion, and Early Rivers peaches with ashes and different amounts of muriate, and sulphate of potash, and cotton-seed meal. The orchard was set in 1894 and a crop of peaches was secured in 1899. The yields secured from the different plats are reported as a matter of record. No conclusions are drawn.

Distribution of sugar, acid, and tannin in pears, W. KELHOFER (*Jahresber. Wädenswil, 6, p. 68; abs. in Jour. Chem. Soc. [London], 78 (1900), No. 453, II, p. 497*).—Determinations of these constituents in the skin, fruit, core, and whole pear are reported. The amounts found in the whole pear were as follows: Sugar, 8 per cent; acid, 12.61; tannin, 2.05.

Prune curing in France (*California Fruit Grower, 25 (1900), No. 632, p. 1*).—The process of curing in vogue at Agen is described.

Drying fruit, HELD (*Württemberg. Wehnl. Landw., 1900, No. 31, p. 504*).—Brief directions for preparing and drying apples, pears, quinces, and cherries.

Length of canning season, H. DYER (*Pacific Rural Press*, 60 (1900), No. 4, p. 52).—A table is given showing the duration of the fruit-canning season in California for 37 consecutive years for fruits and vegetables. The whole season extends from April 6 to December 1.

Commerce in large fruits, J. W. ROBERTSON (*Ontario Fruit Growers' Assoc. Rpt.* 1899, pp. 76-91).—A popular discussion of the shipment of apples from Canadian ports, together with statements of dealers and others regarding the requirements of foreign markets.

Grafting the mango tree, H. KNIGHT (*Queensland Agr. Jour.*, 7 (1900), Nos. 1, pp. 41, 42, pls. 2; 2, pp. 149-151).—The author states that this fruit can be easily and successfully grafted at any time whether the sap is active or dormant. The first three months of the growing season, however, when the sap is most active, is preferred. Pieces of bark without any portions of adhering wood are recommended for use as grafts. Sections of the mango tree, it is said, will keep good for grafting purposes from 3 to 6 months, depending upon the variety and constitutional vigor of the specimen. Directions for grafting mangoes and illustrations of grafts are given.

Pruning the magnolia, S. MOTTET (*Rev. Hort.*, 72 (1900), No. 17, pp. 490, 491).—All the principal branches of *Magnolia abovata lenei* were severely headed in before the flowers opened in the spring. As a result scarcely any flowers were produced that year, but the following spring an unusually abundant florification took place.

FORESTRY.

Forest trees and shrubs, A. MACKAY (*Canada Expt. Farms Rpts.* 1899, pp. 372-376).—A report is given on the forest trees and shrubs under observation at the Northwest Territory Farm. Since 1895 investigations have been conducted on the cost of planting and cultivating forest trees. This test is closed with this report, as the trees now cover the ground so that no further cultivation will be given. It was found that the cost of planting and cultivation of box elders set at different distances from 2½ to 4 ft. varied from \$6.55 to \$7.60 per half acre. For green ash set 2½ ft. apart each way, the cost was \$7.61. When the seed was sown directly in the ground the cost was somewhat greater than when the trees were started in a nursery and afterwards transplanted.

The arboretum is said to contain at the present time 371 species and varieties of trees and shrubs, a considerable portion of which, it is believed, will prove hardy in this climate. A list is given of 10 forest trees suitable for the Northwest Territories. The species recommended are box elder, American cottonwood, Balm of Gilead, American larch, American elm, green ash, sharp-leaved willow, trembling-leaved poplar, Riga pine, and Norway spruce. Each of these trees is described briefly and its relative value for different purposes indicated.

Importance of forest tree growing, D. C. BURSON (*Forester*, 6 (1900), No. 3, pp. 57, 58).—Extracts are given of a paper read by the author, in which some of the more important uses of timber are mentioned. The rapidity with which the forests are disappearing and the vast extent of wood-working industries are said to attract immediate attention to the financial side of forest tree growing. It is stated that

10,000,000 acres of forests are denuded annually, and these should be replanted in order to preserve the equilibrium. By the proper selection of soil, choice of trees, care in planting and cultivating, it is believed that this could be successfully done.

The forestal conditions and silvicultural prospects of the coastal plain of New Jersey, J. GIFFORD (*Rpt. State Geol. New Jersey, 1899, pp. 235-318, pls. 16*).—The coastal plain of New Jersey is said to embrace about 2,500 square miles, 75 per cent of which is wooded. It is slightly rolling, seldom exceeding 200 ft. above sea level. Light sandy soils predominate, although there are many places where heavy clay and coarse gravel are found as well as clay loams and mucky swamp lands. The different species of trees found in this region are enumerated, their uses and distribution being described. Suggestions are given for forest policy to be adopted by the State as well as silvicultural methods. By selection of proper species, planting, and proper care in the prevention of forest fires, the author believes the region could be reforested so as to be of greater economic value than at present. Descriptive notes are given on a number of regions in Europe which are similar to southern New Jersey where reforestation has been successfully carried out.

Forest planting in Norway, DEINBOLL (*Forester, 6 (1900), No. 3, pp. 49-52*).—The former condition of the forests of Norway are described and their present character contrasted. It is stated that a large part of the country is almost barren of timber, so much having been cut away that one-half the country has not enough timber for building purposes and one-fourth not enough for fuel. The amounts cut each season are mentioned and the necessity for replanting is shown. The first artificial planting was begun in 1869 at Bergen, Norway. At the present time the government maintains six large and a number of smaller planting schools, which annually plant about two and a half million trees. The necessity for extending this work is shown and suggestions offered of possible means for the improvement of forest conditions.

Conifers at Murthly Castle, Scotland (*Garden, 57 (1900), No. 1487, pp. 358, 359, figs. 2*).—An account is given of the rate of growth and present condition of a number of species of coniferous plants which have been growing for nearly half a century on this estate. The results do not represent single individuals, but a large number of representatives of the different species. A number of the trees are said to have been severely injured by the cold weather of the winter of 1894-95, when for several days the temperature was below zero F. The results of some of the measurements as well as the ages of the trees are given in the following table:

Growth of conifers at Murthly Castle, Scotland, March 24, 1900.

Species.	Date of plant- ing.	Height.	Cir- cum- ference 5 feet high.	Species.	Date of plant- ing.	Height.	Cir- cum- ference 5 feet high.
		<i>Fect.</i>	<i>Fect.</i>			<i>Fect.</i>	<i>Fect.</i>
<i>Sequoia gigantea</i>	1857	74.11	10.7	<i>Cedrus deodar</i>	1842	61.2	7.4
<i>Abies menziesi</i>	1845	105.10	11.3	<i>Cedrus libani</i>		67.0	12.5
<i>Pinus monticola</i>	1850	79.2	6.2	<i>Cryptomeria japonica</i>	1852	41.7	4.3
<i>Araucaria imbricata</i>	1847	51.0	4.8	<i>Libocedrus decurrens</i>		38.0	4.5
<i>Abies pinsapo</i>	1847	42.6	7.10	<i>Thuja gigantea</i>	1862	57.0	3.7
<i>Abies magnifica</i>	1867	43.3	3.8	<i>Cupressus lawsoniana</i>	1859	48.7	4.2
<i>Abies douglasii</i>	1847	97.4	9.1	<i>Abies japonensis</i>	1885	24.0	1.7
<i>Abies grandis</i>	1852	79.10	6.1	<i>Abies veitchii</i>	1885	20.9	1.4
<i>Abies albertiana</i>	1860	72.1	6.4	<i>Abies concolor</i>	1885	20.1	1.5
<i>Abies nobilis</i>	1847	92.8	6.6	<i>Abies orientalis</i>	1852	49.0	3.0
<i>Abies nordmanniana</i>	1854	74.0	4.9	<i>Pinus jeffreyi</i>		57.0	4.9
<i>Abies hookeriana</i>	1862	39.6	4.0	<i>English yew</i>		30.0	14.3

What the experimental farms have done to stimulate tree planting, W. SAUNDERS (*Canada Expt. Farms Rpts. 1899, pp. 42-45*).—Experimental forest tree planting was begun in 1888 and has been carried on at the Central Farm as well as a number of branch stations since that time. There are now growing on the 5 experimental farms a total of 245,000 trees. In addition there have been distributed from this station 1,261,000 forest trees and 14,000 lbs. of forest tree seeds. The results of this work are said to be everywhere apparent, small plantations of forest trees furnishing shelter for gardens, buildings, and stock, as well as making dwellings more attractive. Experiments have shown that the box elder is one of the most promising forest trees and, as it begins to produce seed when 6 or 7 years old, it is possible to reproduce this species quite rapidly.

Forest belts, W. T. MACOUN (*Canada Expt. Farms Rpts. 1899, pp. 117-123*).—In the Report for 1897 (E. S. R., 10, p. 855) the condition of the forest belts at that time was reviewed and measurements given of the trees at the Central Experimental Farm. In the present report additional measurements are given, this time the diameter of the trees at the height of 4 ft. 6 in. from the ground being recorded. Owing to unsuitability of soil and climate, the specimens of red maple, Norway maple, European mountain ash, buttonwood, horse chestnut, and Kentucky coffee tree have been removed. An account is given of the trees planted in forest belts in 1899, in which about 5,000 trees of 10 varieties were set out. The condition of the arboretum is outlined, together with brief notes on the additions to the arboretum and botanic garden.

Forest tree shelter belt, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899, pp. 319-321*).—A report is given on the forest tree shelter belts which were planted at the Manitoba Farm in 1889. This shelter belt was composed principally of box elder, elm, ash, birch, cottonwood, poplar, spruce, pine, and arbor vitae. The pines and spruces have been injured by the more rapid growing of the deciduous trees. For general planting of wind-breaks in Manitoba, the author recommends the use of box elder, elm, ash, and poplars. The box elders and poplars should be about 2 years old, and the elms and ash 4 years when planted, and should be set 4 ft. apart each way. Close planting will insure straighter and taller trees and sooner cover the ground, stopping evaporation and preventing the growth of weeds.

Notes are given on a new plantation which was set out in the spring of 1898 of maples, ash, and sand cherry. The additions to the arboretum of new trees and shrubs are mentioned and notes given on the value of different species for constructing hedges.

Some observations of Ohio woodlands, J. E. CUNNINGHAM (*Forester, 6 (1900), No. 5, pp. 103, 104*).—The past and present condition of Ohio forests is reviewed,

and it is stated that in 1896 17.4 per cent of the lands which had been previously well forested remained in timber. Certain regions are almost entirely denuded and it is suggested that efforts should be made to maintain at least 15 per cent of the area permanently in forests.

Forest conditions of Cuba, J. GIFFORD (*Forester*, 6 (1900), No. 5, pp. 97-100, pl. 1, fig. 1).—A brief survey of the forest conditions of Cuba, as observed by the author in crossing the island, is given. Even in the mountainous districts the forests are said to be sparse and thin. It is said to be a common practice to burn over uncultivated lands for the improvement of pasturage. A number of the more common forest trees occurring in Cuba are described and suggestions given for future plantings.

Silvicultural prospects of the island of Cuba, J. GIFFORD (*Forester*, 6 (1900), No. 8, pp. 177-183, pl. 1, fig. 1).—Attention is called in this paper to the great advantages of this region in the production of wood and other forest products. The necessity for a botanic garden or experiment station in this region is also shown.

Forestry in western Australia, J. FOLEY (*Forester*, 6 (1900), No. 3, pp. 59, 60).—The forest conditions of western Australia are briefly reviewed and contrasted with the same in this country. Attention is called to some of the more important forest trees of the region, 3 species of Eucalyptus being described, and also the sandalwood tree. It is believed that the conditions would be found favorable for the introduction of some of the American species of maple, hickory, pine, fir, black walnut, catalpa, and white oak.

Reforestation of Campine, L. NÈVE (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 5, pp. 382-394).—Suggestions are given for the clearing and reforestation of this district. Working plans are suggested, in which the cost of reforestation and the returns to be expected are shown. It is claimed that this region may be reforested with *Pinus sylvestris* and at the end of the twentieth or thirtieth year it should produce a revenue of about 7 per cent. The author believes that the average revenue in no case would fall below 4 or 5 per cent, and the advantages to agriculture would warrant the reclamation of this region.

Shrubs and trees, W. S. BLAIR (*Canada Expt. Farms Rpts.* 1899, pp. 260, 261).—Lists are given with brief notes of some 70 species of hardy shrubs and coniferous trees growing at the Maritime Experimental Farm.

Notes on some coniferous trees of North America, N. I. CRAHAY (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), Nos. 3, pp. 163-176; 4, pp. 249-255; 5, pp. 340-351; 6, pp. 415-418; 7, pp. 493-499; 8, pp. 555-558, pls. 6).—Notes are given on the distribution and extent of the coniferous forests of North America and some of their associate deciduous trees. In all, 140 species of trees are mentioned.

Descriptions are given, in which the distribution, habitat, principal characteristics of the trees, the quality of wood, and the uses of nearly all of the more common Coniferæ of North America are mentioned.

The conifers of Holland, B. STOFFEL (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 4, pp. 290-294).—Descriptive notes are given of a number of the conifers growing in Holland, the most important of which are *Picea excelsa*, *Pinus sylvestris*, *Abies pectinata*, *P. strobus*, and Oregon pine.

Notes upon the black locust, K. BUND (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 1, pp. 22-27).—Notes are given on the growth and forest value of *Robinia pseudacacia*. The soil requirements of this tree are shown and the plants which characterize such soils are mentioned. Methods are given for the planting of the black locust tree which in 25 years should attain a height of 20 meters and a diameter of from 0.1 to 0.2 meter. After the twentieth to the twenty-fifth year, the rate of growth is not so rapid. Directions are given for the planting and treatment of the locust tree in nurseries.

The white alder (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 3, pp. 191-193).—A description is given of this tree, which is believed would prove a valuable addition

to the forests of Belgium, especially in the coppice. Three distinct varieties are recognized, the one in which the leaves are greatly elongated and stems more erect being preferred to the others which are of lower or intermediate growth.

The paper industry and forests, C. W. LYMAN (*Forester*, 6 (1900), No. 6, pp. 125-130).—The different sources of paper are briefly indicated and descriptions given of some of the trees that are known to be of value as a source of wood pulp. The processes of pulp manufacture are briefly described, and it is said that in 1899 there were 197 mills in operation in 24 States, having an estimated daily capacity of 3,810 tons. The total consumption of timber for pulp manufacture is said to be about 800,000,000 ft. Large as this consumption appears, it is said to be but 0.4 of 1 per cent of that consumed for lumber and fuel.

Forest fires in 1899 (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 1, pp. 61-63).—During the season of 1899 the forest fires in Belgium burned over 373 hectares, causing a loss of 94,100 francs.

Unextinguished camp fires, C. S. CRANDALL (*Forester*, 6 (1900), No. 3, pp. 65, 66).—As a means for causing forest fires, the camp fire is discussed, and accounts are given of a number of forest fires which can be traced to this source and also of several forest fires which were probably prevented by the discovery and extinguishing by the author of fires that were beginning to spread from abandoned camps.

Forest laws in the United States, T. CLEVELAND, JR. (*Forester*, 6 (1900), Nos. 7, pp. 153-160; 8, pp. 183-186; 9, pp. 210-212; 10, pp. 238-240).—The forest laws of various States and of the Federal Government are briefly reviewed, together with the results obtained in the application of these laws. As a conclusion to the review of the various legal enactments, the author states that "the forest movement has acquired an impetus that can not be checked. That movement has found effective expression in State and Federal laws. These laws are laying the foundation for a perfect system of forest management, and forest management has already reached practical success."

SEEDS—WEEDS.

Influence of varying the temperature on the germination of seeds, W. KINZEL (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, pp. 134-139).—Seeds of conifers, grasses, lupines, buckwheat, and hemp were germinated under similar conditions except temperature. One lot was kept uniformly at 20° C., and the other at 30° for 6 hours, after which the temperature fell to 20°. The effect of this treatment upon the germinative energy and upon the total germinations is shown. The germination of *Pinus sylvestris* was lower in the lot which had been exposed to the higher temperature. With *Picea cretca* and *Larix* sp. the germination was accelerated by the treatment, and in the case of the latter the total germination was a few per cent higher. In the case of the grasses the sprouting was diminished in the case of *Festuca ovina* and both germinative energy and total germinations increased with *Holcus lanatus* and *Anthoxanthum odoratum*. The germination of *Cynosurus cristatus* was accelerated, but the totals were greatest for the constant temperature. Contrary results were obtained with different lots of lupine seed, and the hemp and buckwheat seed kept constantly at 20° C. gave the best germinations.

Tests of the vitality of vegetable seeds, E. H. JENKINS (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 298-304).—A report is given on

tests for vitality of 291 samples of seeds, chiefly of garden vegetables. Since November, 1896, 214 samples of onion seeds, representing the crops of 1896, 1897, 1898, and 1899, have been tested, the results showing that the vitality seems to depreciate with increased age. Comparisons are also made between Connecticut and California grown seed, from which it appears that the California seed sprouts better than the home-grown. Comparisons of the vitality of crops of Connecticut-grown onion seeds in the years 1894-1899 are summarized. The sprouting capacity of different varieties was again tested, with the result that the 3 Globe varieties appeared to be essentially alike, while the White Portugal was distinctly inferior to them.

Spraying for the destruction of mustard, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 194-196).—A number of experiments are reported in which different strengths of sulphate of iron and sulphate of copper were tested for the eradication of wild mustard or charlock. This weed has become one of the most persistent in Canada. The author sprayed barley plats with 5 and 10 per cent solutions of iron sulphate or 2 and 5 per cent solutions of copper sulphate, at the rate of 50 gal. per acre. At this time the grain was between 15 and 20 in. high and the mustard just coming into flower. The iron sulphate solutions were without lasting effect upon the mustard. The copper sulphate damaged the barley to some extent and the stronger solution it is thought lessened the yield slightly, but both strengths almost entirely destroyed the mustard plants present.

In order to ascertain the effect of these solutions upon this weed at younger stages of growth, mustard seed was sown on plats in the farm and when the plants were from 6 to 9 in. high were sprayed with the 5 per cent solution of iron sulphate and the 2 per cent solution of copper sulphate. The iron sulphate solution did not kill all the plants, while the copper sulphate destroyed all within a few days. From the data at hand the author feels warranted in making the following suggestions:

"A 2 per cent solution of sulphate of copper (that is, 2 lbs. in 10 gal. of water) is, all things considered, the most effective, safest (as regards the grain crop), and most economical to use. The spraying should be done thoroughly, and for that purpose 50 gal. per acre will be required. If a heavy rain follows the spraying within 24 hours the operation will have to be repeated. In order that the work may be effective, spraying should not be delayed after the mustard plants have reached a height of 6 to 9 in. If allowed to grow taller than this, stronger solutions would be necessary and in larger quantities, as the grain would then largely protect the mustard."

Results of experiments on the spraying of charlock, P. S. FOULKES (*Jour. Univ. Extension Col., Reading [England], Sup.* 9, 1900, pp. 55-59).—Experiments were conducted on crops of wheat, barley, and oats for the destruction of charlock. Applications of copper sulphate solutions of from 1 to 6 per cent at the rate of from 25 to 50 gal. per acre were employed. The applications were made at differ-

ent times and under varying climatic conditions. An almost total failure is reported from one series of experiments; elsewhere the effect of spraying was to retard the growth of the charlock. It is concluded from the experiments that if care is taken in the spraying and the application be made on a clear, still, bright day, spraying for charlock is undoubtedly an effective means for its destruction. The application should be made before the plants come into flower, and a 2 per cent solution at the rate of 50 gal. per acre gave the best results. If these conditions are complied with, one spraying should be sufficient to destroy the weeds. If the weather is unfavorable or if rain falls within 24 hours after spraying, a second application should be made.

Seeds and seed tests, C. T. MUSSON (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 856-862).—An account is given of seed tests performed at Hawkesbury Agricultural College and the importance of seed testing is shown. The methods pursued are described and comparisons given between the standard germinations of a number of seeds and the percentages of germination obtained at this station.

Tests of the vitality of grain and other seed for 1899, W. T. ELLIS (*Canada Expt. Farms Rpts. 1899*, pp. 38-40).—A tabulated report is given of the results of seed tests for vitality made during the season, 2,058 samples of seed being tested, more than four-fifths of which were wheat, barley, oats, and peas. A report is also given showing the results of grain tests made for each of the 8 provinces of Canada.

Testing grass seed, C. D. WOODS (*Maine Sta. Bul.* 65, pp. 112-114).—Notes are given on 103 samples of clover and grass seed which were examined by the station during 1899. Tables are given showing the results of the separate analyses as well as the kinds of weed seed found in the different samples examined.

The worst weeds of the Northwest, J. FLETCHER (*Canada Expt. Farms Rpts. 1899*, pp. 184-194, figs. 8).—Lists are given of weeds of the Northwest Territories, they being divided into the worst weeds and occasional weeds. The plants in question are popularly described and, so far as known, remedies are suggested for their destruction. The following list of weeds are considered especially noxious and every effort should be put forth to destroy them when detected or prevent their introduction to new localities: Stink weed or penny cress, wild oat, Canada thistle, tumbling mustard, hare's ear mustard, false flax, ball mustard, wild mustard, shepherd's purse, lamb's quarters, wild buckwheat, Russian pigweed, cow cockle, great ragweed, Canada fleabane, blue bur, peppergrass, and squirrel-tail grass.

A brief description is given of weeder for use in extensive operations, and notes are given on the condition of the wheat crop relative to the occurrence of weeds and weed seeds. The crop of this season is said to have been exceedingly free from weed seeds.

Destruction of weeds by chemical means, O. LUGGAR (*Farm Students' Rev.*, 5 (1900), No. 11, pp. 163-165, fig. 1).—A popular article on weed destruction by spraying with solutions of iron or copper sulphates.

DISEASES OF PLANTS.

Miscellaneous notes on fungus diseases, W. C. STURGIS (*Connecticut State Sta. Rpt. 1899*, pt. 3, pp. 277-282).—Notes are given on the downy mildew of melons, a destructive disease of potatoes, injury to peas, leaf spot of alfalfa, and a disease of peppers.

The downy mildew of melons (*Plasmopara cubensis*), while common upon cucumbers, has been previously reported but once as occurring upon muskmelons within the State. During August a number of specimens were sent to the author from vines which were badly infested with the disease, every leaf on a 2-acre field being dead. Investigation showed the fungus mentioned above. The same disease is liable to attack cucumbers, and spraying experiments for its prevention do not seem to have been conducted with uniform success. The use of Bordeaux mixture as a partial preventive, or forcing the melons and cucumbers by starting them earlier in the season and transplanting so that the fruits will be matured before the usual time for attacks of this mildew, are recommended.

The disease of potatoes described was characterized by the blackening and shriveling of the stalks which upon examination appeared to be hollowed from an inch or so below the surface to 2 to 8 in. above. The similarity in appearance between these hollow stalks and the injury caused by potato-stalk borers led to a careful search, but no insects were found. A microscopical examination showed neither fungus nor bacteria. Upon the author's recommendation, all diseased vines and those for a hill or two beyond the limit of the affected area were collected and burned, and no further trouble was experienced by the grower.

A serious injury to peas is described, which is caused by the leaf-spot fungus *Ascochyta*. There seems to be reason to believe that the fungus attack is not primarily above ground but that it may be present in the seed. Should the disease threaten serious injury in the future, it would be advisable to obtain seed from regions where it is not present, and to select land which has not borne peas for a number of years. In case it is necessary to use the same land for two or more successive crops, as soon as the crop is harvested, all vestige of vines should be gathered and burned.

A brief note is given on leaf spot of alfalfa (*Pseudopeziza medicaginis*). This disease has been fully described in the report of the Iowa Station for 1897 (E. S. R., 10, p. 263). If the disease appears early in the season, the alfalfa should be cut and fed immediately. If later in the season, one practical means of combating it is by continuous cropping, or watching for its appearance, which would generally be at a few points in the field, and cutting and burning the affected plants.

The disease of peppers described is that of anthracnose (*Colletotrichum nigrum*). This is reported to have occurred during the past summer in fields in which at least 25 per cent of the fruit was rendered worthless by the fungus. No experiments have been attempted for its prevention, but based on experiments conducted elsewhere it is thought that irrigation and mulching would prove advantageous.

A contribution to the knowledge of cereal rusts, H. KLEBAHN (*Ztschr. Pflanzenkrankh.*, 10 (1900), No. 2, pp. 70-96, figs. 3).—Investigations are reported on the occurrence of rusts on wheat, barley, and rye, inoculation experiments with sporidia upon the teleutospore hosts, rust spores in the air, investigations on the alternate generations of rusts, wintering of rusts, effect of using seed from infected plants, and studies on the anatomy and biology of the yellow rusts.

The author's investigations led to the following conclusions: The sporidia of cereal rusts can not infect cereals, nor can the sporidia of any of the heteroecious rust fungi infect their teleutospore hosts. From carefully conducted experiments there seems little to substantiate the claim that rusts may be communicated by sowing seed from infected plants. Such cases may be usually traced to outbreaks of the disease in the early spring. The probable agency of winds and animals in transmitting rusts is recognized, and further investigations along this line are in progress. There appears to be too little attention paid to the æcidial phases of the rusts, and these should be known for every species. The brown rust of rye (*Puccinia dispersa*) has its æcidia upon *Anchusa arvensis* and *A. officinalis*, but not the wheat brown rust (*P. triticea*), nor *P. simplex*. The anatomical and biological investigation of *P. glumaris* showed some important specializations that require further study. There was no indication that any of the rust fungi, which were without a perennial mycelium, are able to infest their host plants the following growing season, the presence of disease being attributed to a new infection.

Parasites of wheat, L. MANGIN (*Overs. K. Danske Vidensk. Selsk. Forhandl.*, 1899, pp. 213-272, pls. 3, figs. 17; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 3, p. 366).—In this paper the conditions of wheat attacked by *Septoria graminum* and *Leptosphaeria herpotrichoides* are described. The spores of *S. graminum* put out germinating filaments which perforate the epidermis, never entering through the stomata, their action being purely chemical. The specific characters of the fungus are constant and its ascospore form is as yet unknown. The second disease, to which the name "piétin" is given, is caused by the *Leptosphaeria* and is often accompanied by a number of other fungi, among them *Ophiobolus graminis*, *Pyrenophora trichostoma*, and *Aspergillus circinatus*, the latter being considered a new species. Cultures, according to the author, demonstrated that *Diceltyosporium opacum* is the conidial form of *Leptosphaeria herpotrichoides*.

On the so-called "grain" of wrapper tobacco, W. C. STURGIS (*Connecticut State Sta. Rpt.* 1899, pt. 3, 262-264, pl. 1).—It is stated that tobacco leaves used for wrappers frequently exhibit, after curing, numbers of minute, blister-like pimples thickly scattered over the surface of the leaf, giving it a somewhat granular appearance. This

"grain" occurs on all kinds of tobacco which have been examined. Microscopic examinations of the blisters show a dense deposit of crystalline substance which tests have shown to be oxalate of lime. This being the case, it might be supposed that the addition of lime to soil would make the "grain" in cured tobacco more prominent, but specimens taken from different plats showed that there was no relationship apparent between the amount of lime used as fertilizer and that occurring in the leaves. As to whether the "grain" is formed during the process of curing or is present in the growing leaves, nothing definite can be stated as yet. The author believes it probable that tobacco plants under certain conditions take up greater quantities of lime than they can utilize and deposit it in the tissues, and that it becomes visible only after the shrinkage in thickness incident to the process of curing.

Further notes on the pole burn of tobacco, W. C. STURGIS (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 265-269*).—In the Annual Report of the station for 1891 (E. S. R., 3, p. 773) the pole burn of tobacco was described at some length, and the isolation of a number of bacteria from the surface of leaves, as well as species of *Cladosporium*, noted. Recently leaves were collected which showed the beginnings of pole burn, the tissues along the larger veins being of a darker color and extremely tender. These areas were subjected to examination and 2 series of cultures maintained, one of which developed an *Alternaria* and a species of yeast, while the other, which had been sterilized, developed a bacillus. From a doubly sterilized leaf were developed in the course of 10 days a large colony of a bacillus of the type of *Bacillus subtilis*, and smaller colonies related to *B. megatherium*, and a few small colonies of *Micrococcus*.

The author concludes, as far as the organisms associated with the earliest stages of pole burn are concerned, that *Alternaria* is the only one which occurs in any abundance, and that it occurs only on the surface of the leaf and not in the internal tissues. The presence at this time of *Alternaria* and other organisms not found previously merely indicates that under certain atmospheric conditions any saprophytic fungus which may be present in the curing barn may attack the dead tissues of the leaves and start in them a process of disintegration, which will almost surely be followed by true bacterial decay.

The remedial measures recommended in the previous report are reaffirmed.

On fractional fertilization of muskmelons as a preventive of disease, W. C. STURGIS (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 270-273, dgm. 1*).—In the report of the station for 1898 (E. S. R., 11, p. 754) an account was given of favorable results attending the use of tobacco stems as a mulch for melon vines. An experiment was planned to test the effect of small applications of plant food from time to time

throughout the growing season for the prevention of the wilt disease. A fertilizer consisting of 4 parts of potash, 4 of nitrogen, and 1 of phosphoric acid was applied to hills of melons at different times during the growing season, with the result that such plants maintained their vigor, and on the fertilized plats there was no yellowing of vines or spotting of leaves.

The conclusion was reached that the diseases ordinarily present and abundant in other parts of the field were primarily due to a deficiency of available plant food, and that the indications of actual disease were merely incidental. The fact that where additional fertilizer was applied there was an almost complete absence of the wilt and spotting of the leaves is believed by the author sufficient to warrant further experiments along this line.

Notes on some tomato diseases, F. S. EARLE (*Alabama College Sta. Bul. 108, pp. 19-33*).—Notes are given on bacterial black rot, bacterial wilt, sclerotium wilt, leaf blights, and leaf mold or mildew.

The black rot or blossom end rot, as here described, is attributed to an undescribed species of *Bacillus*. This disease has been under investigation for a number of years, and a preliminary paper upon it was read by the author before the Botanical Club during the meeting of the American Association for the Advancement of Science in 1899. This paper is printed in full, from which it appears that this disease has been known for a long time. It has been usually attributed to attacks of fungi, the principal ones being *Macrosporium tomato* and *Fusarium solani*. It has been shown by the Vermont Station (E. S. R., 8, p. 992) that these fungi are unable to produce the disease. Tomatoes attacked by this disease show small, irregular, watery areas, usually at the blossom end. Investigations by the author have shown that this region is crowded with bacteria, which have been isolated, and inoculation experiments conducted by which the disease has been readily reduced. The bacillus is of medium size, stains readily, and as yet no spore formation has been detected. It grows readily on the flesh of sound green tomatoes, causing rot, but can not penetrate the cuticle unaided. It is strictly aerobic, developing only on the surface of culture media. It fails to grow on a number of other plants, such as the fruit of sweet peppers, onions, cabbage, kohlrabi, etc. Summarizing his studies, the author concludes that the cause of the black rot, or blossom end rot, is a bacillus. The method of infection in nature has not been fully determined, but it is probable that it is through the agency of minute insects. The presence of species of thrips in considerable abundance suggested this insect as a possible agency in spreading the disease. When the bacillus is carried deeply into the tomato by an open wound, as is done by the bollworm, the result is a wet rot, quickly involving the entire fruit. In seeking a remedy for this disease, the author believes that insecticides, rather

than fungicides, should be tested. Experiments are planned by which the author hopes to demonstrate the agency of thrips in distributing the bacilli and in inducing the disease.

Experiments on the control of the bacterial wilt and the sclerotium wilt by means of culture and the use of fertilizers are reported elsewhere (p. 552).

Observations on tomato blight. C. E. MEAD (*New Mexico Sta. Bul.* 33, pp. 44, 45).—Fourteen varieties of tomatoes were grown under the supervision of the author to ascertain the variety best adapted to the climate, both for its yield and blight resistance. In consequence no spraying was done. Diseased plants began to appear early in June, and it seemed evident that there was considerable difference in the susceptibility to blight. The varieties Stone and Dwarf Aristocrat seemed to be most resistant, while Mayflower was very badly attacked. The previous recommendation that tomatoes be grown in the shade during the hot weather to check the attacks of blight was investigated by growing tomatoes alternating with rows of corn, but there was no appreciable difference between the number of blighted plants in the shade and open ground. As mechanical recommendations the author suggests the early removal of all diseased vines from the field, thorough ridding of plants of insect pests, and the maintenance of a thorough state of cultivation of the soil.

Dry rot, brown spot, or Baldwin spot of apples, W. T. MACOUN (*Canada Expt. Farms Rpts.* 1899, pp. 96-99).—A report on this disease was made in 1896 (E. S. R., 9, p. 850) in which it was described at considerable length. During subsequent years it has been under investigation, and in 1897 and 1898 19 varieties of apples at the Experimental Farm were affected, some crops having been so badly injured that the fruit was almost worthless. Although the trees had been thoroughly sprayed the fungicides appeared to have been without effect in reducing the disease.

From replies to circulars sent out by the author to the different fruit regions of Canada and the United States, it appears that at least 60 varieties are affected, the Baldwin seeming to be attacked the most. It is thought possibly this may be due to the fact that this apple is more extensively grown than any other variety in those regions where the spot is most prevalent. In range it extends from the Atlantic to the Pacific, being most prevalent in eastern Ontario, Quebec, British Columbia, and the eastern United States. Opinions of growers differ as to the cause, and the author quotes extensively from the Vermont Station Report for 1899 (E. S. R., 12, p. 258). As yet no remedy is known.

On the prevention of raspberry anthracnose by cultural methods, W. C. STURGIS (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 74-76).—The raspberry anthracnose is briefly described and the investigations of Thaxter (E. S. R., 2, p. 482), and the experiments

conducted at the New York State Station (E. S. R., 9, p. 762), are reviewed. The latter seemed to indicate that for the prevention of this disease the use of fungicides was valuable, although the increased yield did not justify the expense.

An account is given of a badly infested plat of vines, in which severe pruning, followed by thorough cultivation and throwing the dirt over the diseased stems, resulted in an excellent growth of young shoots nearly free from the disease. As a possible explanation for this, it is stated that the diseased canes were largely removed by the pruning, and an unusually dry season prevented the development of the fungus.

White rot of the grape, L. RAVAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 37, pp. 335-337, pl. 1).—This disease is said to be due to the fungus *Coniothyrium diplodiella* or *Charrinmia diplodiella*. The fungus is considered as a semiparasite, being incapable of invading sound tissue, but whenever by accident the epidermis of the grapes is broken it readily attacks and destroys the fruit. This disease is said to be a quite common accompaniment of hailstorms, the hail injuring the grapes and permitting the entrance of the fungus. Experiments with fungicides for the prevention of the disease have shown that the spores of white rot will germinate in much stronger solutions of copper than those of the black rot, on which account any fungicide should be considerably stronger. As this fungus is dependent upon external agencies for its infection of the grape, preventive treatment can not be recommended as in the case of other diseases. It is stated that this fungus, unlike the *Botrytis* which causes the gray rot of grapes, does not produce any oxidizing diastase which is considered the cause of the condition of wine known as "casse."

Stem-rot disease of carnations, W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 236-238*).—This disease was previously described by the author (E. S. R., 10, p. 262), the cause being determined to be a species of *Fusarium*. Other investigators have recorded similar diseases of cotton, tomatoes, muskmelons, and watermelons. In 1897 the author found snapdragon plants affected by a similar disease. In 1898 asters were similarly affected, so that it seems probable that carnation, snapdragon, and aster plants are attacked by the same or closely related organisms.

The methods by which the spores are wintered over and the infection of the plant are unknown. Attempts to inoculate healthy plants above ground have failed, while seemingly healthy plants one after another became diseased in a field as well as after being set in the forcing-house benches. On account of the extreme susceptibility of the variety, William Scott, this was discarded.

A series of culture experiments was conducted, in which the soil was removed from around plants to a depth of about 2 in. After the stems had become dry, they were coated with Bordeaux mixture, and the soil replaced. From time to time a number of plants were noticed

to be badly diseased or dead, and were removed. The experiment was conducted with soils consisting of coal ashes and peat and of compost. The average number of diseased plants was 4.3 and 3.4, respectively, for the 2 soils.

From the fact that healthy plants, one after another, became diseased in the benches, that coating them with fungicides did not prevent attacks, or removing diseased branches save any of the plants, the author is led to believe that the fungus gains access to the tissues of the host either through the rootlets or some portion of the root system considerably below the surface of the soil, and when the top begins to wilt, the plant is already in the last stages of the disease.

Some important fungi and fungicides, C. O. TOWNSEND (*Maryland Sta. Bul.* 65, pp. 64-69, figs. 2).—Popular descriptions are given of the causes of various plant diseases and directions given for the preparation and application of fungicides for their prevention.

Experiments on club root (finger and toe) (*Jour. Univ. Extension Col., Reading [England]*, Sup. 9, 1900, pp. 47-52; also *Bd. Agr. [London] Rpt. Agr. Education and Research, 1899-1900*, pp. 96-98).—An account is given of soil treatment with lime, basic slag, caustic lime, chalk, and gas lime for the prevention of club root of cruciferous plants. All the lime preparations were found to give favorable results from their use.

The potato disease (*Gard. Chron.*, 3. ser., 28 (1900), No. 717, pp. 222, 223).—The writer reports a very serious outbreak of potato rot in Ireland whereby the crop will be very materially lessened. Spraying was not practiced to any considerable degree.

Some tobacco diseases, J. F. GOUTIÈRE (*Jour. Agr. Prat.*, 1900, I, No. 16, pp. 569-571).—Notes are given on the injury done by the orobanche (*Phelipaea ramosa*) and descriptions of the mosaic disease of tobacco.

The smuts observed in Belgium during 1898, H. VANDERYST (*Rev. Gén. Agron. Louvain*, 9 (1900), No. 7, pp. 297-302).—A report is given of 48 species of smuts, representing 10 genera, that have been observed in different parts of Belgium. The distribution of these different smuts throughout the country is indicated.

Smut of sugar cane, C. A. BARBER (*Dept. Land Records and Agr., Madras, Vol. II, Bul.* 39, pp. 155, 156, pl. 1).—Notes are given on a serious outbreak of *Ustilago sacchari*. The smut is described and burning affected areas is recommended.

Concerning the proper use of artificial fertilizers for sugar beets and the relation with beet diseases, F. KUDELKA (*Bl. Zuckerrübenbau*, 7 (1900), No. 8, pp. 113-121).

Virescence and fasciation due to parasites, M. MOLLIARD (*Rev. Gén. Bot.*, 12 (1900), No. 140, pp. 323-327, figs. 3).—A case of virescence in *Trifolium repens*, due to attacks of *Polythrincium trifolii*, and a fasciation of *Raphanus raphanistrum* are described and figured.

Investigations on *Rhizoctonia violacea*, M. GÜNTZ (*Fähling's Landw. Ztg.*, 48 (1899), No. 19, pp. 731, 732; abs. in *Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 15, pp. 506, 507).—In an alfalfa field which had been devastated by this root parasite, potatoes, Jerusalem artichokes, and bush beans were planted with the result that some of each kind of plant were killed by the fungus.

The genetic relationship between *Roestelia koreænsis* and *Gymnosporangium japonicum*, M. SHIRAI (*Ztschr. Pflanzenkrankh.*, 10 (1900), No. 1, pp. 1-5, pls. 2).—The relationship existing between these two fungi is shown by cultures upon Juniperus and pear leaves.

Note on *Gloeosporium cactorum*, J. F. CLARK (*Amer. Florist*, 15 (1900), No. 611, pp. 841, 842, fig. 1).—Notes the occurrence of this fungus on a number of species of cacti.

Fruit diseases and how to treat them, L. C. CORBETT (*West Virginia Sta. Bul.* 66, pp. 199–235, figs. 23).—A number of the more common fruit diseases are popularly described and suggestions given for their prevention. A spray calendar is given for preventive treatment of the diseases of the apple, cherry, currant, grape, nursery stock, peach, apricot, nectarine, pear, plum, raspberry, blackberry, and strawberry. Formulas and directions for making insecticides and fungicides complete the bulletin.

The destruction of pear rust, C. FREIHERR VON TUBEUF (*Arb. K. Gesundheitssamt, Biol. Abt., Leaflet 3, Apr., 1900, pp. 4, figs. 5*).

American gooseberry mildew in Ireland, G. MASSEE (*Gard. Chron., 3. ser., 28* (1900), No. 713, p. 143, fig. 1).—Notes the appearance of *Spherotheca mors-uræ* in Ireland and recommends spraying with a solution of potassium sulphid for preventing its attack.

Currant leaf spot, WEISS (*Prakt. Bl. Pflanzenschutz, 3* (1900), No. 1, pp. 1–3).—Notes on *Gloeosporium ribis* and means for its prevention.

Banana disease (*Trinidad Bot. Dept. Bul. Misc. Inform., 1900, No. 24, p. 254*).—Notes the destructive occurrence of *Marasmius seminiatus* on banana plants. Experiments show that under good cultural conditions the fungus lives as a saprophyte, becoming destructive when the plants are weakened from any cause.

The diseases and enemies of coffee, G. DELACROIX (*Les maladies et les ennemis des caféiers. Paris: Challamel, 1900, 2. ed. enl., pp. 216, figs. 50*).

The black rot in Jura during 1899, F. JOUVET (*Vigne Amer. et Viticult. Europe, 24* (1900), No. 5, pp. 146–149).—Outbreaks of black rot were observed June 5 or 6, followed by second, third, and fourth appearances June 10 to 12, July 28 to 31, and August 5 to 7. Spraying experiments were conducted in which the best results were obtained from 5 applications of Bordeaux mixture. The addition of resin was without value, as shown by the results.

Notes on oidium in Burgundy, P. PACOTTET (*Rev. Vit., 1900, No. 332, pp. 473–476*).

The prevention of *Oidium tuckeri*, J. WORTMANN (*Mitt. Weinbau u. Kellerr., 1900, No. 1, pp. 1–6; abs. in Centbl. Bakt. u. Par., 2. Abt., 6* (1900), No. 9, pp. 301, 302).—Notes the serious occurrence of this mildew in 1899. Investigations lead to the belief that it is wintered over in the bark of the vine. Sulphur is recommended as a preventive means.

Combating oidium on grapes, KULISCH (*Landw. Ztschr. Elsass-Lothringen, 1900, No. 17, pp. 238, 239*).

Diseases of plants, R. HARTIG (*Lehrbuch der Pflanzenkrankheiten. Berlin: J. Springer, 1900, pp. IX+290; noted in Allg. Forst u. Jagd Ztg., 76* (1900), June, pp. 205, 206).—A third and revised edition of "The diseases of trees."

Fungus diseases of shade trees, W. LOCKHEAD and M. W. DOHERTY (*Canad. Hort., 23* (1900), No. 4, pp. 133–141, figs. 12).—Notes are given on tree-root rot (*Agaricus melleus*), root rot of conifers (*Trametes radiciperda*), heartwood rots (*Polyporus sulphureus*, *P. betulinus*, etc.), apple-tree canker (*Nectria ditissima*), spruce canker (*N. cucurbitula*), coral spot canker (*N. cinnabarina*), larch canker (*Peziza willkommii*), pine tree fungus (*Trametes pini*), pine cone fungus (*Peridermium pini*), cedar apples (*Gymnosporangium* sp. and *Restelia* sp.), lichens, maple-leaf blotch (*Rhytisma acerinum*), and pine-leaf cast (*Lophodermium pinastri*), together with suggestions for preventing injurious attacks upon their hosts.

Notes on the *Peridermium* of *Pinus strobus* (*Bul. Soc. Cent. Forst. Belg., 7* (1900), No. 8, pp. 577–579).—This fungus is said to have spread rapidly through the forests of Belgium during the past 2 or 3 years and is becoming a serious enemy to the plantations of white pine. The different forms of the fungus, one of which grows on pines and the other upon species of *Ribes*, are described. It is said that the Peri-

dermium developed in July and August on the bark of *Pinus sylvestris* is not to be confounded with that occurring on *P. strobus*.

Some causes of pine-leaf cast, FROMBLING (*Ztschr. Forst. u. Jagdw.*, 32 (1900), No. 8, pp. 462-467).—Unfavorable atmospheric conditions are said to cause pine-leaf cast.

Combating pine-leaf cast, KIENITZ (*Ztschr. Forst. u. Jagdw.*, 32 (1900), No. 6, pp. 364-373).—Spraying young pine trees with Bordeaux mixture between the first and fifteenth of August is recommended for the prevention of leaf cast.

A fungus disease of cottonwood, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899*, p. 322).—It is reported that for the past 2 or 3 seasons the cottonwood (*Populus deltoides*) has been seriously affected by a fungus disease which destroys the leaves. During the summer a growth, resembling rust, makes its appearance on the leaves, especially on the young succulent ones, which in a short time are discolored and fall from the tree. In the following spring a large portion of the wood is found to be in a dying condition. The value of fungicides for controlling this disease will be a subject of investigation during the coming season.

The influence of copper fungicides on the quality of wine, E. CHUARD (*Chron. Agr. Canton Vaud*, 13 (1900), No. 18, pp. 451-457).—The claim is made that in years when atmospheric conditions are favorable for ripening the grapes the application of copper solutions has no effect upon the quality of wines, but in cold seasons unfavorable for ripening the fruit that process is further retarded by the action of the fungicide on the plant whereby its functions of growth are prolonged and the maturation delayed.

Formalin as a fungicide for bean anthracnose, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899*, p. 323).—A series of experiments were conducted in which beans were soaked for 2 hours in a solution of 1 oz. of formalin to 1 gal. of water. The germination of the beans was not appreciably affected by either this or stronger solutions, and the test seems to indicate that formalin is a useful deterrent to the bean anthracnose.

Potassium permanganate as a fungicide, M. TRUCHOT (*Vigne Amer. et Viticult. Europe*, 24 (1900), No. 6, pp. 187-190).—The addition of 125 gm. of potassium permanganate to 100 liters of copper fungicide or a simple solution of 125 gm. of potassium permanganate, 3 kg. lime, and 100 liters of water are recommended as fungicides for spraying grapes.

Acetate of copper as a fungicide, J. DURAND (*Vigne Amer. et Viticult. Europe*, 24 (1900), No. 4, pp. 118-120).—In efficiency and ease of application this compound is thought to equal Bordeaux mixture.

Preparation of Bordeaux mixture, G. BATTANCHON (*Vigne Amer. et Viticult. Europe*, 24 (1900), No. 7, pp. 198, 199).—Directions are given for the proper preparation of a neutral Bordeaux mixture. The method described is essentially that given in Farmers' Bulletin 38 of this Department (E. S. R., 8, p. 240).

ENTOMOLOGY.

Report of the entomologist, J. FLETCHER (*Canada Expt. Farms Rpts. 1899*, pp. 159-184, figs. 15).—Brief popular notes are given on a large number of injurious insects. The Hessian fly is reported as having been unusually destructive during the past year. From an examination of specimens collected in various parts of Manitoba, it is believed that there is only one brood of the Hessian fly in that region. The remedies recommended against this insect are late sowing of wheat, burning of rubbish, and burning or plowing under the stubble. *Polyg-*

notus hiemalis and *Merisus destructor* are reported as parasites of the Hessian fly. The destructive pea aphid caused serious losses to sweet peas and field peas at Ottawa and other points. Experiments were conducted in spraying plants with the tobacco and soap mixture composed of 10 lbs. of tobacco leaves and 2 lbs. of whale-oil soap to the barrel of water. Most of the plant lice were destroyed. Brief notes are given on *Uroleiferis aspturagi* and *U. 12-punctata*. As remedies against these insects the author recommends dusting plants in summer with lime, spraying with arsenites, beating the plants, and the use of trap plants.

The black violet aphid was very destructive to violets under glass at Toronto. Fumigation with tobacco is not to be recommended, since violets are usually injured by this substance. The use of hydrocyanic-acid gas for greenhouse fumigation is preferred. Descriptive biological and economic notes are also given on *Bryobia pratensis*, *Phlyctenia ferrugalis*, and *Lyda multisignata*.

The report on the apiary at the Central Experimental Farm is made by J. Fixter. Eighteen colonies of bees were removed from winter quarters on April 1, and 6 were placed in the house apiary, 6 in the sheltered apiary, and 6 in the exposed apiary. It was noted that while the weather was cool with cold winds, bees which were sheltered were flying, while those which were exposed did not leave the hive. Brief practical suggestions are given on the management of bees in summer.

Some insects of the year 1899, R. H. PETIT (*Michigan Sta. Bul.* 180, pp. 117-141, figs. 15).—The red spider is reported as injurious to plum, apple, peach, chestnut, and honey-locust trees. The greatest amount of damage was done to apple, plum, and peach trees. The red spider was observed usually on the underside of the leaves, but on both sides of chestnut leaves. Various distortions were produced in the leaves by the attack of these mites.

The European fruit scale (*Aspidiotus ostryæformis*) is reported as injurious to soft maple, currant, mountain ash, and apple trees. The natural enemies of this insect observed in Michigan are *Smilia miscella* and *Chilocorus bivulnerus*. A detailed description is given of this species of scale louse.

Economic and biological notes are presented on the following species: *Tischeria malifoliella*, *Lorostege sticticalis*, *Systema tenuata blanda*, *Disomyia triangularis*, *Epicauta cinerea*, *Diabrotica vittata*, *Typophorus canellus*, *Euphoria inda*, and *Selandria rubi*.

Brief suggestions are given regarding formulas and the use of the more common insecticides.

A recent observation on *Filaria nocturna* in *Culex*, G. C. LOW (*British Med. Jour.*, 1900, No. 2059, pp. 1456, 1457, pl. 1).—The author studied the life history of this *Filaria* in *Culex ciliaris*. In

order to study the anatomy of the mosquito with reference to the possible migration of the worms, sections of infected mosquitoes were made after embedding in celloidin. It was found that the young filariæ, after reaching their highest stage of development, did not remain passive in the thoracic muscles but left that tissue and, traveling forward in the direction of the head, passed into the loose cellular tissue which abounds in the prothorax in the neighborhood of the salivary glands. After a short stay in the thorax the worms passed forward into the head and coiled up in the connective tissue below the cephalic ganglion and the salivary duct. From these positions the filariæ make their way into the proboscis through an independent opening in the labium. From this position it is easy to understand how they may infect man.

The clover-root borer (*Hylastes obscurus*), F. M. WEBSTER (*Ohio Sta. Bul.* 112, pp. 143-149, pl. 1).—This insect passes the winter in Ohio in all stages, but chiefly in the adult condition. The author gives brief descriptions of the insect in its different stages. A table is presented showing the condition in which the insect is found during the different months of the year. At the beginning of the year adults and larvæ are present, but pupæ are seldom seen. The first eggs were found on May 17, and pupæ which were found on March 2 and May 31 came from hibernating larvæ. The new brood of larvæ begin work during the first week of June. The insect does not attack young clover during the first year, but seems to prefer clover during the second year from the seed. The injury is done largely before the first of August.

An experiment was tried at the station in devising a method for combating this insect. In June, 1897, a plat of ground 16 by 20 ft. was seeded to red clover. On July 7, 1899, an examination of the clover plants disclosed the presence of larvæ of this insect. On the following day the plat was plowed to a depth of from 4 to 5 in. An examination of this plat on August 10 resulted in finding only a single pupa and 3 nearly full-grown larvæ 2 or 3 in. below the surface, while other larvæ and pupæ were found deeper in the soil. On August 11 an insect cage was placed over a part of this plat to prevent the escape of adult insects. The plat was examined on October 19 with the result that only 4 live beetles were found. The beetles were abundant at the same time in outside fields.

The author believes that deep and thorough plowing immediately after harvesting the first crop of clover will result in the destruction of the majority of these insects.

Combating the gypsy moth (*Porthetria dispar*), Y. SJÖSTEDT (*Meddel. K. Landthbr. Styrelse*, 1900, No. 1, pp. 29, pls. 2, figs. 2).—The author reports an unusually serious outbreak of the gypsy moth during the past 2 years in the southeastern part of Sweden, in Blekinge and Kal-

mar counties. The gypsy moth was reported from Karlskrone in 1840 and even as late as 1891 was considered a rare insect in that region. The area which was infested during the outbreak under discussion amounted to about 100 sq. kilometers. The food plants which the insect seemed to prefer were oak, poplar, willow, birch, apple, peach, beam tree, spruce, blueberry, clover, and grasses. The infested country was of a rough nature and contained many large stone piles and stone walls, in which the eggs were laid.

A government appropriation was secured and work was begun in the spring in the destruction of the eggs. The egg masses were treated for this purpose with black varnish, $\frac{1}{3}$ kg. of this substance being sufficient to treat 200 egg masses. In all, 2,025 kg. of black varnish and 660 kg. of Raupenleim were employed in the spring work. The total number of eggs destroyed by these methods was estimated at 377,500,000. The spring work extended from April 11 to May 13, and during this time 7,941 stone piles and 36,048 meters of stone wall were examined. The number of men employed varied from 88 to 115, and the total number of days' work in the spring operations was 1,839. The first gypsy moth larvæ hatched out during the last days of April while the temperature varied from zero to 18° C. In general, the larvæ were found to hatch during the time between the first appearance of green and the development of the leaves. During the summer the infested area was carefully examined, the work extending from July 10 to July 21. Stone walls which were badly infested with eggs were surrounded with a line of narrow boards which had been smeared with Raupenleim in order to prevent the escape of the larvæ. The total number of days' work in the spring and summer operations was 2,290 and the total expense was about \$925.

Among the natural enemies of this insect, the author mentions starlings, cuckoos, crows, magpies, and a number of parasitic Hymenoptera and Diptera. The author's observations upon the life history of the gypsy moth may be summarized as follows: The eggs which have survived the winter hatch at about the time of the first vegetative development. The number of eggs in 20 egg masses which were carefully counted varied from 172 to 682, with an average of 339. The larvæ undergo 4 distinct developmental stages. The larval period varies from 9 to 10 weeks and the pupal stage from 12 to 14 days. The males appear during the last week in July and the females during the first week in August. The deposition of the eggs begins in from 2 to 6 hours after fertilization and occupies from 7 to 12 days.

A new method of combating the gypsy moth, RÖRIG (*Arb. K. Gesundheitsamte, Biol. Abt.*, 1 (1900), No. 2, pp. 255-260, figs. 2).—The author, after inspection of the work of the gypsy moth commission in Massachusetts in fighting this insect, came to the conclusion that the methods adopted there did not give hope of ultimate success.

In Germany the gypsy moth has never become so injurious as in the United States, but the author suggests that it may become so at any time.

The methods for destroying the eggs of the gypsy moth which have thus far been practiced are collecting and burning, painting with *Raupeleim*, and treatment with a mixture of tar and kerosene. The author's chief objection to these methods is that some of the eggs in each cluster may be brushed from the tree and escape destruction. He has devised a cheap and convenient apparatus which is claimed to be well adapted for the destruction of the eggs. This consists of a tank which holds about 200 cc. of kerosene. The escape pipe is in the form of a small tube, and the whole apparatus may be carried in the hand or at the end of a pole of any required length according to the height of the egg clusters. A string attached to a valve and extending down the pole allows the operator to regulate the amount of kerosene discharged upon each egg cluster.

Washes and sprays for combating plant lice, woolly aphids, and similar pests, E. FLEISCHER (*Ztschr. Pflanzenkrankh.*, 10 (1900), No. 2, pp. 65-70).—The author conducted experiments with Halali, kerosene emulsion, Verminol, insect soaps, and Sapokarbol. A 2 per cent solution of Halali was ineffective and the author found that in order to destroy all insects a 16 per cent solution must be employed. The substance was found to be somewhat injurious to the plant tissues. The kerosene emulsion employed contained extracts of tobacco or quassia. A 5 per cent solution was found to be very effective and did not cause injury to the plants. The author believes that Halali is a very good remedy for plant lice, but that the practical objection to it is the high price. The kerosene emulsion, Verminol, and insect soap are not believed to possess advantages which outweigh their costliness. The author especially recommended Sapokarbol as a remedy for the destruction of woolly aphids.

A test of spray nozzles, N. O. BOOTH (*Missouri Sta. Bul.* 50, pp. 85-115, figs. 10).—A comparative study was made of 30 kinds of nozzles from different manufacturers, with reference to the following points: Height of spray or distance which the spray could be thrown perpendicularly with various pressures; width, shape, and distribution of the spray at the point where it was considered most efficient; size of the drops; amount of liquid discharged by each nozzle in a given time; liability of the nozzle to clog; liability to dribble; durability, and method of attachment.

The author classifies the different nozzles in the following manner: Class I. Nozzles which throw a solid more or less round stream. Class II. Nozzles in which the spray is somewhat broken directly by the action of the margin of the outlet. Class III. Nozzles in which the stream, after having passed the outlet proper, is broken into a

spray by striking against the projecting parts of the nozzle. Class IV. Nozzles in which a rotary motion is given to the liquid in a chamber near the outlet. Class V. Nozzles in which the liquid escapes in 2 converging streams which, acting upon each other, break the liquid into a spray.

In determining the height of spray, no account was taken of the highest point to which isolated drops were thrown, but an attempt was made to establish what is called the spraying distance, or the distance from the mouth of the nozzle to the point where the bulk of the spray is best broken up. It was found practically impossible to determine in what shape the spray is most desirable. The most essential points seemed to be the securing of a spray which, when passed at a uniform rate over any surface, will cover every part touched with a film of liquid of equal thickness. In order to compare the different nozzles with reference to this matter, they were made to throw a spray at the spraying distance of each one down into galvanized-iron boxes 6 in. square, which were placed closely side by side. In each case the fluid was allowed to run until those cans which received most were nearly full.

For determining the size of the drops thrown by different nozzles, a barrel and a half of brownish-black ink was made with logwood and the spray was directed against blank sheets of paper placed at the best distance for each nozzle. The papers were then photographed.

The quantity of water discharged by the different nozzles was determined in quarts per minute at a pressure of 30 lbs.

In testing the matter of clogging a 6-lb. Bordeaux mixture was used, and it was found that when this mixture was carefully and cleanly prepared none of the nozzles clogged during the 5 minutes which were allowed for the test.

Tests showed that many otherwise excellent nozzles had the disadvantage of dribbling to a considerable extent.

The question of durability is one not easy to determine, since in most cases it will be considered better to buy a new nozzle than to continue the use of one which has become defective through wear.

The author states that no general-purpose nozzle has been perfected. The choice of a nozzle must necessarily depend largely upon the kind of work for which it is to be used. One of the most important points in determining the choice of a nozzle is the distance to which the spray must be thrown.

Bees and bee culture, A. KUNAKHOVICH (*Selsk. Khoz. i Lysov.*, 195 (1899), Oct., pp. 145-210; Nov., pp. 327-406, figs. 50).—An elaborate discussion of the problems connected with apiculture, including the anatomy of the bee, varieties of bees, bee food, bee products, breeding of bees, natural swarming, artificial swarming, removal of queens, a system of apiculture with 2 queens in each hive, an economical study of apiculture, honey plants, etc.

An unusual application of propolis by bees in the wild state, X. TAPIE (*Rev. Internat. Apicult.*, 22 (1900), No. 9, pp. 165-167).—The author made observations on a swarm of bees which was living in a cavity under a large rock. The bees had constructed a wall of propolis for protective purposes.

Report of the entomologist, A. D. HOPKINS (*West Virginia Sta. Rpt.* 1899, pp. 25-36).—The chief work of the entomological department of the station for the year was upon forest insects and life zones. The author gives a detailed statement of various trips made in the State for the purpose of studying these matters. Progress is reported in the study of timothy varieties. Recent reports from correspondents concerning the San Jose scale indicate that this insect has not become a serious pest in any counties of the State west of the mountains.

Insect notes, W. E. BRITTON (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. 240-244).—Notes are given on the appearance of the pea-plant louse (*Nectarophora destructor*) in the State. It is reported that *Schizoneura rileyi* was injurious to the branches of elm trees during the season. Irregular, warty growths are produced on the branches or trunks of the trees by this insect. The spruce-bud louse (*Adelges abieticolens*) was found infesting the twigs of spruces. Notes are given on a number of scale insects, including *Lecanium armeniacum*, which was found upon grapes and other fruit trees. A beetle which infested wheat middlings and did considerable damage in such situations proved to be *Lamophlaus pusillus*. Garden primroses and also the native evening primrose were badly injured by the attacks of *Halitica marevagans*. It is stated that fall cankerworms are much less numerous than during previous years.

How insects are studied at the Ohio Agricultural Experiment Station, F. M. WEBSTER (*Ohio Sta. Bul.* 114, pp. 165-173, pls. 2).—The author presents a popular account of the insectary and breeding cages at the experiment station, and of the methods of collecting, rearing, preserving, and labeling insects.

Note on Collops bipunctatus, T. D. A. COCKERELL (*New Mexico Sta. Bul.* 33, pp. 50, 51).—A brief account of the known distribution of this insect.

The female of Eciton sumichrasti, with some notes on the habits of Texan ecitons, W. M. WHEELER (*Amer. Nat.*, 34 (1900), No. 403, pp. 563-574, figs. 4).—Notes on the appearance and biology of species of the foraging ants.

Synopsis of food habits of the larvæ of the Sesiidæ, W. BEUTENMÜLLER (*Canad. Ent.*, 32 (1900), No. 10, pp. 301-303).—The author gives brief notes for the purpose of indicating the host plants of these insects and the parts of the host plants which are attacked.

The Coccidæ of Brazil, A. HEMPEL (*Rev. Museu Paulista*, 4 (1900), pp. 365-537, pls. 8).—Descriptive, biological, and economic notes on a large number of species of Coccidæ, some of which are described as new.

Effect of lime on the oyster-shell bark louse, W. T. MACOUN (*Canada Expt. Farms Rpts.* 1899, pp. 94-96).—During the previous year in experiments conducted for another purpose it was noted that whitewash was a very effective remedy for the oyster-shell bark louse. Further experiments are now in progress, from which no definite conclusions can be drawn as yet. The insecticide as used in this experiment is composed of 6 gal. skim milk, 30 gal. of water, 60 lbs. of lime, and 10 lbs. of salt. Certain trees which were not treated with whitewash received a spray of tobacco water and whale-oil soap made by using 10 lbs. of tobacco, 2 lbs. of soap, and 40 gal. of water. The trees were sprayed June 1 and again June 6, with the result that nearly all the insects were destroyed.

An enemy of the Colorado potato beetle, C. E. MEAD (*New Mexico Sta. Bul.* 33, pp. 47-49).—This article has been previously noted (*E. S. R.*, 11, p. 767).

Preliminary notes on the rate of growth and on the development of instincts of spiders, ANNIE B. SARGENT (*Proc. Acad. Nat. Sci. Philadelphia*, 1900, No 2, pp. 395-411, pls. 2).—This paper contains a record of observations on *Argiope cophinaria* and *Agalena neriia*. It was observed that increase in size takes place between the

molts and is dependent on the food. Molting did not occur at regular intervals, but according to the amount of food. Cannibalism was not noted while the young were in the cocoon. Experiments indicated that young spiders could withstand a very cold, moist atmosphere but not a warm, dry one.

Inspection and care of nursery stock, W. E. BRITTON (*Connecticut State Sta. Rpt. 1899, pt. 3, pp. 245-251*).—A revised form of Bulletin 129 of the station (E. S. R., 11, pp. 270, 271).

Bisulphid of carbon for the destruction of insects in stored seeds (*Amer. Gard., 21 (1900), No. 303, p. 679*).—Brief notes on the method to be adopted in using this insecticide.

The chemistry of insecticides, F. T. SHUTT (*Canada Expt. Farms Repts. 1899, pp. 148, 149*).—An analysis of Paris green indicated the presence of 44.2 per cent arsenious acid, 4.56 per cent of which was soluble in water. A kerosene-carbolic emulsion containing 2 gal. kerosene, 1 gal. of water, 1½ lbs. of soap, and 2 pt. of crude carbolic acid is reported as effective in the destruction of the oyster-shell bark louse and tree borers. The emulsion as just given should be diluted in 8 parts of water. A correspondent suggested the addition of blue vitriol to the kerosene emulsion for use on dormant trees. Experiments indicated that the blue vitriol caused the immediate separation of the constituents of the emulsion, and therefore this combination can not be recommended. A Bordeaux mixture, 4:4:40, was mixed with a strong decoction of tobacco in equal proportions. A slight separation took place after long standing, but it is believed that if this mixture be sprayed in a fresh condition the tobacco would have no injurious effect upon the Bordeaux mixture.

Some important insecticides, fungicides, and apparatus for their application, W. G. JOHNSON, C. O. TOWNSEND, and H. P. GOULD (*Maryland Sta. Bul. 65, pp. 55-63*).—A popular account of the insecticides most commonly applied in the destruction of biting and sucking insects, with brief notes on the time of application of these insecticides and formulæ for their preparation.

Some important spraying apparatus and other accessories, H. P. GOULD (*Maryland Sta. Bul. 65, pp. 70-89, figs. 16*).—This article contains a popular discussion of bucket pumps, knapsack pumps, barrel pumps, kerosene pumps, horizontal pumps, nozzles, suggestions for the use of spraying apparatus, and a spray calendar.

FOODS—ANIMAL PRODUCTION.

Preliminary report upon the composition and properties of the fat in "firm" and "soft" pork, F. T. SHUTT (*Canada Expt. Farms Rpts. 1899, pp. 151-155, pl. 1*).—In view of the importance of firm pork for the bacon industry, analyses were made of the ham and shoulder in what was regarded as firm pork of excellent quality and in soft pork of very inferior quality. The results follow:

Composition of fatty tissue in firm and soft pork.

	Water.	Salt.	Nitrogen.	Nitrogenous tissue.	Fat by difference.	Olein in bacon.	Palmitin and stearin in bacon.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Firm pork:							
Ham	15.56	2.73	0.504	3.15	78.56	50.05	28.51
Shoulder	6.53	1.12	.285	1.78	90.57	58.33	52.24
Soft pork:							
Ham	12.50	1.84	.243	1.52	84.27	66.37	17.93
Shoulder	2.67	.48	.142	.89	95.96	76.94	19.02

"It is to be observed that the percentage of water in the fatty tissue of the 'firm' is greater than in the fatty tissue of the corresponding part of the 'soft' bacon. Also, that the percentage of tissue other than fat, that is, of a nitrogenous nature, was also greater in the 'firm' than in the 'soft.' This falls into line with the results [previously] stated, . . . since the water for the most part is contained in or held by the nitrogenous tissue. This would indicate that the walls of the cells containing fat proper are thicker in the 'firm' than in the 'soft' or 'tender' bacon. Further, it is to be noticed that the amounts of salt present are also larger in the 'firm' than in the 'soft' bacon. This is accounted for by the assumption that the salt, like the water, is held by the nitrogenous tissue to a greater extent than in the fat.

"The percentages of fat are, from a consideration of the foregoing statements, necessarily greater in the 'soft' than in the 'firm' bacon. The fat proper consists of olein, fluid at ordinary temperatures, and palmitin and stearin, solid at ordinary temperatures. The data show that the percentage of olein is much greater in the 'soft' than in the 'firm' bacon, while as a natural consequence the percentages of palmitin and stearin are greater in the 'firm' than in the 'soft' bacon. These facts furnish the cause of the greater softness in the 'soft' or 'tender' bacon."

The composition of the rendered fat of firm and soft pork was also determined, as well as the usual constants.

"[In the author's opinion] the melting point of the fat from the 'soft' bacon is practically 10° C. lower than that of the 'firm' bacon. The specific gravities in both series are so close that it is not possible to use this constant as a means of differentiation or for deducing therefrom any information respecting the relative composition of the fats. The saponification equivalent likewise appears to be of little value in the diagnosis. The Reichert number shows the practical absence of volatile fatty acids in both series, though there is an indication of larger traces of the presence of such in the shoulder fat than in that of the ham. The 'iodin absorbed' is of great value in this investigation. From it may be calculated the percentage of olein or liquid fat present in a fat. The data here presented clearly demonstrate the larger amount of olein in the 'soft' fat, a fact that gives the explanation for the greater softness or tenderness of the 'soft' bacon."

These investigations are being continued, and in order to determine the effect of food on the composition of the pork, the olein, palmitin, and stearin, and the ratio of the two latter to the former was determined in the bacon of several young pigs ranging from 23 to 42 lbs. in weight.

Feeding experiments with steers to test the value of cocoa shells, F. ALBERT (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 972-975).—A test was made at the Lauchstädt Experiment Station to investigate the feeding value of cocoa shells, a by-product from chocolate manufacture. Two lots of steers were used. Both lots were fed diffusion residue, alfalfa hay, straw, molasses bran, cotton-seed meal, and wheat bran. In addition, lot 1 was given cocoa shells, 0.5 kg. per 1,000 kg. live weight being fed at the beginning of the test, and the amount gradually increased to 10 kg.

During the test lot 1 made an average gain of 1.8 kg. per head and lot 2, 1.7 kg. The author concludes that cocoa shells are a satisfactory and healthful feeding stuff and that steers readily learn to eat them. Cocoa shells are regarded as intermediate in feeding value between meadow hay and wheat bran.

The value of maize-germ-molasses feed for fattening lambs, F. ALBERT (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 987-994).—At the Lauchstädt Experiment Station the value of a feeding stuff made of maize germ and molasses was tested. Two lots of 17 and 20 lambs each were used. The test proper began July 28, 1897, and closed October 15. Feeding a constant basal ration of 70 kg. of beet chips, 15 kg. of pea straw, 3 kg. of ground peas per 1,000 kg. live weight, a mixture of 7.5 kg. of the molasses feed, 1.128 kg. of wheat bran, and 4.276 kg. of rape-seed cake per 1,000 kg. live weight, was compared with one of 1 kg. of wheat bran, 4.325 kg. of rape-seed cake, and 6.283 kg. of corn meal. About the middle of the test the amount of molasses feed was increased to 10 kg.

The average daily gain of the lambs on the molasses feed was 0.154 kg. when 7.5 kg. was fed, and 0.127 kg. when 10 kg. was fed. Lambs fed the corn-meal ration gained on an average 0.108 kg. per head daily.

The principal conclusions were that maize-germ-molasses feed is very satisfactory for lambs, and gives better results than corn meal. As shown by slaughter tests, it produced better flesh than the similar ration without molasses.

Experiments with lambs to study the effect of different concentrated feeding stuffs on the character of the tallow, F. ALBERT (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 975-987).—The effect of different feeding stuffs on the tallow was tested with 4 lots of cross-bred English lambs at the Lauchstädt Experiment Station. After a preliminary period of about 2 months, the feeding test proper began February 25 and closed June 14. The lambs were shorn about a month before the beginning of the test. All the lots were fed a basal ration of ensiled beet pulp, meadow hay, and straw. In addition, lot 1 was fed maize and sunflower-seed cake; lot 2, ground peas and wheat bran; lot 3, peanut cake and barley bran; and lot 4, wheat bran and rape-seed cake. The character of the fat of these different feeding stuffs was investigated. A number of lambs sickened or died during the test, and at the close lot 1 contained 7 lambs, lot 2 4, and lots 3 and 4 8 each. The average daily gain ranged from 0.148 to 0.203 kg. per lamb. The lambs were slaughtered and the tallow and other fat examined. The principal conclusions were that the fat consumed in the concentrated feeding stuffs may exercise a marked influence upon the character of the tallow. Especially good results, both as regards the improvement of the flesh and tallow, were obtained with sunflower-seed cake. Good results also attended the feeding of rape-seed cake and bran. Peas and peanut cake gave less satisfactory results.

Feeding experiments with pigs on the value of sugar and influence of increased protein consumption, F. ALBERT (*Landw. Jahrb.*, 28 (1899), No. 5-6, pp. 943-962).—A test was made at the Lauchstädt Experiment Station with 6 lots of 2 pigs each to determine the feeding

value of sugar and to learn the amount of protein and non-nitrogenous material best suited for fattening pigs. Lots 1 and 6 were fed a normal ration consisting, per 1,000 kg. live weight, of 80 kg. of cooked potatoes, 80 kg. of skim milk, 10 kg. of barley, furnishing 5 kg. of protein and 28 kg. of non-nitrogenous nutrients. The nutritive ratio was 1:5.7. Lots 2 and 5 were fed a ration rich in protein, receiving per 1,000 kg. live weight, 80 kg. of cooked potatoes, 40 kg. of skim milk, 5 kg. of meat meal, and 12.5 kg. of ground barley. This ration had a nutritive ratio of 1:4.92, and furnished 7.5 kg. of protein and 28 kg. of nitrogen-free nutrients. Lots 3 and 4 were fed a ration deficient in protein consisting, per 1,000 kg. live weight, of 80 kg. of cooked potatoes, 20 kg. of ground barley, and 10 kg. of sugar, furnishing 2.5 kg. of protein and 40 kg. of nitrogen-free material. This ration had a nutritive ratio of 1:15.

This ration was fed from February 27, 1898, to April 27, this being regarded as a preliminary period. From April 27 until the close of the test proper, June 15, the amount of potatoes fed the different lots was reduced to 60 kg. The amount of the other feeding stuffs was also changed somewhat, but the proportion of protein to nitrogen-free material was about the same.

At the beginning of the preliminary period the pigs weighed about 50 kg. each. During the test the pigs of lot 1 and 6 gained 0.718 kg. per head per day; those in lots 2 and 5, 0.661 kg.; and those in lots 3 and 4, 0.929 kg. The pigs receiving the large amount of protein had not gained as much as was expected; therefore, the test was continued 77 days with lots 2 and 5, the ration being increased by the addition of 12 kg. of sugar per 1,000 kg. of live weight. One pig was dropped out on account of illness. The average daily gain of the others was 0.525 kg. All the lots were slaughtered and the flesh judged by an expert. The ratio of dressed weight to live weight was practically the same, ranging in the different lots from 76.1 to 76.6 per cent. In the author's opinion the differences between the individual members of the lots were more marked than between the different lots. The belly fat and the lard of the different lots were examined.

The principal conclusions follow: A ration containing 5 kg. of digestible protein and 28 kg. of digestible nitrogen-free material per 1,000 kg. live weight suffice for producing a gain of 0.5 kg. per head per day. Increasing the digestible protein did not have a beneficial effect. Meat meal is a suitable nitrogenous feeding stuff when only gains in weight are considered. Sugar, when fed in a ration furnishing 5 kg. of digestible protein and 40 kg. of digestible nitrogen-free nutrients per 1,000 kg. live weight, gave very satisfactory results. Better results may be expected if a ration containing sugar and having a wide nutritive ratio supplements for a few weeks a period with a normal ration. Definite results regarding the effect of the different rations on the composition of flesh and fat were not drawn.

Report of the poultry manager, A. G. GILBERT (*Canada Expt. Farms Rpts. 1899, pp. 205-223, pl. 1*).—The work of the poultry department during the year is briefly reported. Generally speaking, pullets laid more eggs than year-old hens or those 3 or 4 years old. The eggs of older hens were larger and if sold by weight would be more valuable. The weight of a dozen eggs ranged from 1 lb. and 11 oz. in the case of the Barred Plymouth Rock, White Brahma, Black Minorca and Andalusian hens, to 1 lb. and 4 oz. in the case of Brown Leghorn pullets. Brief statements are made on the poultry hatched, the rations fed to old hens and pullets. In a test comparing whole ground grains with poultry having limited runs the following results were obtained: Five Barred Plymouth Rock cockerels fed whole grain gained in 14 weeks 18 lbs. 12 $\frac{3}{4}$ oz.; 5 White Plymouth Rock cockerels fed ground grain gained in the same time 20 lbs., 3 $\frac{1}{4}$ oz.; and 5 Silver Laced Wyandottes fed a mixture of whole and ground grains gained 15 lbs., 14 $\frac{1}{4}$ oz. In every case the chickens were fed per head daily 12 oz. of grain (wheat, barley and corn, 2:1:1). Crossbred cockerels, when confined in small coops and fed an ordinary ration, gained in 4 weeks from 12 $\frac{3}{4}$ oz. to 1 lb. 5 oz. The 3 best birds at the end of 5 months weighed on an average of 5 lbs. 1 oz. each.

Brief statements are made concerning the breeding pens, the feeding of chickens and pullets, and other points usually touched upon in these reports.

Feeding chickens for growth, G. M. GOWELL (*Maine Sta. Bul. 64, pp. 89-96*).—A number of tests with chickens are reported. In the first, the effect of small coops v. houses with small yards, on rapidity of growth, was studied. Forty Barred Plymouth Rocks, White Wyandottes, and light Brahmas (Eaton strain), were confined in small coops such as are used by English and French chicken and poultry fatteners, 4 chickens being placed in each coop. All were fed porridge made of skim milk and mixed meal containing corn meal, wheat middlings, ground oats and animal meal, 10:8:5:4. Twenty chickens of the same breeds were confined in houses with small yards and fed the same ration. All the chickens were 130 days old at the beginning of the trial, which covered 35 days. The average gain of the chickens confined in coops was 2.23 lbs., and of those in houses with yards 2.47 lbs., the amount of dry meal required per pound of gain being 5.94 and 6.52 lbs., respectively. The author calculates that the value of the chickens was increased \$19.39 by fattening. "In these tests greater total and individual gains and cheaper flesh production were secured from birds with partial liberty than from those in close confinement. The labor was less in caring for the yarded birds. The cooped birds were very quiet and did not appear to suffer from confinement."

To determine the effects of age on gains in weight, 45 Plymouth Rock chickens, 177 days old at the beginning of the trial, were fed under the same conditions as above, 20 chickens being confined in coops

and the remainder in houses with small yards. In 21 days the average gain of the chickens confined in coops was 0.87 lb., 8.2 lbs. of grain being required per pound of gain. The average gain per chicken of the lot fed in houses with yards was 0.92 lb., the grain required per pound of gain being 7.36 lbs. The profits are estimated at 8.25 cts. per chicken. In the author's opinion these tests show that it is more profitable to fatten young chickens, for although the difference in age of the lots in the 2 trials reported was not great, much more satisfactory results were obtained with the younger birds.

The effect of green food was tested with 24 Plymouth Rock chickens 140 days old at the beginning of the trial. They were confined in lots of 4 in small coops and fed for 4 weeks on a ration of mixed meal and skim milk as described above. Two of the lots received no green food; the others were fed once a day all the finely chopped green rape they would eat during the last 2 weeks of the trial. When no green food was supplied, the gains ranged from 3.7 to 4.3 lbs. per coop; when rape was fed, from 3.5 to 4.4 lbs.

Breeding for egg production, G. M. GOWELL (*Maine Sta. Bul.* 64, pp. 97-102).—A record is given of the eggs laid by the hens employed in experiments on the possibility of securing breeds which shall excel in egg production. Of the 236 hens employed, 39 laid 160 or more eggs and 35 laid less than 100 eggs in a year. Great variations were observed in the laying capacity of the hens and in the regularity of laying, although all the hens were given the same food and care, and the chickens in each breed tested were selected for their uniformity. It was noticed that the eggs from hens that laid the greatest number were on an average smaller in size than those from hens producing fewer eggs, and the percentage of infertility was also greater in the former case than in the latter.

Coffee substitutes, C. D. WOODS and L. H. MERRILL (*Maine Sta. Bul.* 65, pp. 103-107).—The composition of 8 sorts of cereal coffee is reported and the food value of this class of goods discussed. It was found that, as claimed, the samples examined were free from true coffee. The infusion did not have a high food value, containing, when made according to directions, from one-third to one-twentieth as much solid matter as skim milk.

Inspection and analyses of foods, M. A. SCOVELL (*Kentucky Sta. Bul.* 86, pp. 51).—As an aid to the interpretation of the Kentucky pure-food law, a number of provisional definitions of food materials and articles used in their preparation are suggested, and the analyses made in accordance with the law are reported of 727 samples of dairy products, spices, flour, vinegar, etc. Of these, 290 were found to be adulterated.

Fodders and feeding stuffs, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1899, pp. 143-147).—Analyses are reported of broad-leaf hay (*Spartina cynosuroides*), hay tea, cotton-seed meal, the seed of lamb's-quarters (*Chenopodium album*). The latter had the following percentage composition: Water, 9.82; fat, 6.78; protein, 14.19; carbohydrates, 63.91; crude fiber, 1.27, and ash, 4.03. Judged by composition only, the author believes the seed to have a comparatively high feeding value. Its percent-

ages of fat and protein—the two most important nutrients—place it approximately midway between corn meal and bran. Since these seeds are very small and possess a hard integument, it seems most probable that if fed without previous grinding or boiling the greater number of them would pass through the animal undigested, in which case not only would they be of no food value, but harm would be done by their dissemination over the farm in the resulting manure."

Feeding-stuff inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 63, pp. 75-88).—Analyses of feeding stuffs made in accordance with the State law are reported, the constituents determined being protein and fat. The materials examined include cotton-seed meals, gluten meals, linseed meals (old and new process), corn-and-oat feeds, oat chop, oat feeds, dairy feeds, poultry food, rice feed, mixed feeds of different sorts, animal meal, beef scraps, ground beef scraps, ground beef cracklings, and a raw ground bone meal.

Rice flour and bran as a feeding stuff, C. DUSSERRE (*Chron. Agr. Canton Vaud*, 13 (1900), No. 16, pp. 472-474).—The value of these feeding stuffs is discussed.

Potato pomace, J. M. BARTLETT (*Maine Sta. Bul.* 65, pp. 115, 116).—Two analyses of potato pomace (the residue from the manufacture of starch) are reported.

The employment of the residue from wine making as a feeding stuff, S. BIELER (*Chron. Agr. Canton Vaud*, 13 (1900), No. 16, pp. 374-377).—A discussion of the methods of preserving and feeding the residue from wine making.

Feeding nonsaccharine sorghums, C. E. MEAD (*New Mexico Sta. Bul.* 33, pp. 46, 47).—Brief statements are made concerning a practical test of the feeding value of brown durra, red and white Kafir corn, black rice corn, large African millet, and yellow millo maize forage. In general, satisfactory results were obtained.

Concerning the formation of glycogen from protein, B. SCHÖNDORFF (*Arch. Physiol. [Pflüger]*, 82 (1900), No. 1-2, pp. 60-85).—On the basis of experiments with frogs fed casein, the author concludes that glycogen can not be formed in the body from a proteid which does not possess a carbohydrate group.

The relation of nitrogen to chlorids in the stomach contents during digestion, J. WINTER and FALLOISE (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 24, pp. 1646-1648).

On the relation of the reducing power of normal urine to the amount of certain nitrogen contents present, J. H. LONG (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 6, pp. 309-327).—The reducing power of uric acid and creatinin in relation to the total reducing power of urine was investigated.

Concerning the substances in the blood soluble in ether, R. WEIGERT (*Arch. Physiol. [Pflüger]*, 82 (1900), No. 1-2, pp. 86-100).—Artificial digestion experiments are reported. In the author's opinion his experiments show that blood contains a substance soluble in ether which is not fat.

Concerning digestion in birds, L. PAIRA-MALL (*Arch. Physiol. [Pflüger]*, 80 (1900), No. 11-12, pp. 600-627).—An experimental study of the physiology of digestion in birds, with a critical review of the literature of the subject.

Steers, J. H. GRISDALE (*Canada Expt. Farms Rpts.* 1899, pp. 54-58, pls. 3).—The gains made by 8 lots of 4 steers each during a period of 16 weeks are tabulated, together with the cost of the gain and the net profit. No conclusions as to the relative effects of the different rations are given. The gains made by 29 steers fed in the spring are briefly reported. On a ration of silage, hay, and mixed grain the average daily gain was 2.06 lbs. Brief statements are also made concerning feeding tests made with steers in 1900.

Steer feeding experiments, 1898-99, R. ROBERTSON (*Canada Expt. Farms Rpts.* 1899, pp. 252-254).—A test of the comparative value of different breeds of steers at the Nappan Experimental Farm is briefly reported. They were fed from December 1 to March 16 such feeding stuffs as mixed meal, turnips, silage, hay, and straw. Four

Polled Angus steers gained 965 lbs.; 4 Herefords gained 805 lbs.; 4 Shorthorns, 760 lbs.; and a second lot of 4 Shorthorns, 675 lbs., while 4 scrubs gained 755 lbs.

Cattle, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899, pp. 311, 312*).—Brief statistics are given of the Brandon Experimental Farm herd, and of a test made with 2 lots of 3 grade Shorthorn steers each as to the comparative value of wheat and oat straw. The steers were fed for 110 days, silage and chopped grain being given in addition to the straw. During the last 55 days flaxseed was also fed. They were purchased at 3 cts. and sold for 4.85 cts. per pound. The average daily gain per head of lot 1 (fed wheat straw) was 1 lb. 3 oz. and of lot 2 (fed oat straw) 1 lb. 1 oz., the profits on the 2 lots being \$20.11 and \$19.64, respectively.

Cattle, A. MACKAY (*Canada Expt. Farms Rpts. 1899, pp. 383-385*).—Barley, oat, and wheat straw, and native and brome grass hay, when fed in addition to silage and meal, were compared with 5 lots of steers at the Indian Head Experimental Farm. The lots fed straw contained 4 animals and those fed hay 2 animals each. In 4 months the gain per steer on the different rations was 126.25, 91.66, 162.5, 127.5, and 180 lbs., respectively. In every case the cost of a pound of gain was 7 cts.

Sheep fattening experiments in 1899, J. GRUDE (*Tidsskr. Norske Landbr., 7 (1900), No. 2, pp. 77-85*).—A test with 2 lots of 100 lambs each to compare linseed cake and oats when fed with hay and turnips showed that in 30 days on the former ration the gain per lot was 399.5 kg. and on the latter 320 kg. On account of the high price of the oil cake, oats were considered the more economical feed.—F. W. WOLL.

Experimental pig feeding, J. MAHON (*Queensland Agr. Jour., 7 (1900), No. 1, pp. 23, 24*).—In a test with 2 lots of 4 pigs each on the value of molasses added to a ration of ground barley, the amount of food required per pound of gain by the lot fed barley was 5.5 lbs., and the amount required by the lot fed barley and molasses was 5.08 lbs.

Some experiments in pig feeding (*Jour. Bd. Agr. [London], 7 (1900), No. 1, pp. 28-33*).—A discussion of experiments by Campbell at Yorkshire College, Leeds, and by Harris at Calne. The latter were made with the aid of the Wilts County Council and other local assistance.

Pigs, J. H. GRIDDALE (*Canada Expt. Farms Rpts. 1899, pp. 60-62*).—Brief statements are made concerning the pigs kept and the feeding tests carried on. In a test of the value of rape, begun August 2, 6 pigs were fed until November 30 and 5 until December 29 on a quarter of an acre plat of rape, and during part of the time were given some grain or mangolds also. The 2 lots produced 1,434 lbs. of pork, the cost of a pound of gain being 3.42 cts. According to the author this is materially less than the average cost of pork produced on grain alone.

Swine, R. ROBERTSON (*Canada Expt. Farms Rpts. 1899, pp. 255, 256*).—The author gives details of the work of the year with swine at the Nappan Experimental Farm. When fed an average of 20 lbs. per head daily of skim milk in addition to meal, 3 Berkshire pigs, weighing 77 lbs. at the start, gained 358 lbs. in 110 days. Three Berkshires, weighing 216 lbs. at the start and fed on an average of 25 lbs. daily of skim milk in addition to meal, in 125 days gained 469 lbs. In 165 days 4 Yorkshires weighing 132 lbs. at the start and fed the same ration gained 768 lbs. A test from which definite conclusions were not drawn is also reported on the comparative value for pigs of wheat shorts, buckwheat, corn meal, and crushed oats, 2:1, and pea meal and crushed oats, 2:1. Corn meal and pea meal made firm pork, that of the pigs fed corn meal being slightly more satisfactory. Pork made from buckwheat was soft.

Swine, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899, pp. 312, 313*).—The Brandon Experimental Farm herd of swine is described as well as a test on the value of coarse grain with a small proportion of bran for pigs. Four Berkshire pigs fed bran, oats, and barley in about the proportion of 1:7:2 gained 166 lbs. in the 11 weeks of

the first period at a cost of 2.76 cts. per pound. During a second period of 4 weeks there was a gain of 84 lbs. at a cost of 2.42 cts. per pound, on a ration of bran, oats, and barley 1:1:2. In a third period of 5 weeks the gains amounted to 126 lbs., the cost of a pound of gain being 1.98 cts. The grains were fed in the same proportion as during the second period. The financial side of the test is also discussed.

Poultry, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1899, pp. 314, 315*).—The advantage of a long and a short period of fattening was studied with cockerels and ducks at the Brandon Experimental Farm. Eight cockerels weighing 28 lbs. 12 oz., fed a mixture of equal parts of ground oats, wheat, and barley, mixed with water to the consistency of thin porridge, gained 6 lbs. 1 oz. in 21 days, the cost of a pound of gain being $3\frac{1}{3}$ cts. In a second period of 14 days the gains amounted to 4 lbs. and the cost of a pound of gain was 7 cts. Five crossbred Pekin ducks under a year old were confined in a yard and fed well-moistened chopped wheat, oats, and barley, 1:1:1. They were given some vegetable matter such as cabbage and turnip leaves and supplied with water. The ducks weighed 23 lbs. 2 oz. at the beginning of the test. In 24 days they gained 5 lbs., the cost of a pound of gain being $8\frac{1}{3}$ cts. During the second period, which covered 9 days, there was a gain of 15 oz., the cost of a pound of gain being $17\frac{1}{3}$ cts.

Preservation of eggs, F. T. SHUTT (*Canada Expt. Farms Rpts. 1899, pp. 223-226*).—The author reports comparative tests of the value of limewater, water glass, glycerin, and distilled water for preserving eggs. Some eggs were also coated with paraffin and kept in bottles. The experiment demonstrated, in the author's opinion, "the value of saturated limewater as an egg preservative. As far as our experience goes, no other fluid is its equal, the eggs from this preservative being far and away superior to those kept by the other methods here stated."

DAIRY FARMING—DAIRYING.

Feeding experiments with palm-nut cake, palm-nut residue, linseed meal, castor-bean meal, and peanut meal for milch cows, E. RAMM, C. MOMSEN, and T. SCHUMACHER (*Milch Ztg., 29 (1900), Nos. 19, pp. 291-294; 20, pp. 309-311; 22, pp. 340, 341; 23, pp. 353-355, figs. 4*).—These feeding stuffs, fed in like quantities in rations otherwise identical, were compared in tests with 6 cows, covering in all a period of about 3 months. The tests proper lasted 4 days each and were preceded by preliminary periods varying from 6 to 11 days. The peanut ration was tested in the first and seventh periods, the palm-nut cake in the second and fourth, and the others in intermediate periods. Some of the principal results are shown diagrammatically, and are summarized in the following table:

The yield and quality of milk and butter fat from cows fed different rations.

Ration.	Yield of milk per 1,000 kg. live weight per day.	Yield of fat per 1,000 kg. live weight per day.	Fat content of milk.	Solids-not-fat in milk.	Iodin absorption number of fat.
	<i>Kg.</i>	<i>Kg.</i>	<i>Per cent.</i>	<i>Per cent.</i>	
Peanut meal	27.35	0.91	3.38	8.78	37.2
Palm-nut cake	24.09	.98	4.14	8.52	27.5
Palm-nut residue	24.23	.91	3.82	8.94	27.7
Linseed meal	28.31	1.03	3.71	8.82	47.2
Castor-bean meal	23.79	.79	3.38	8.76	47.1

The castor-bean meal, tested as a new feeding stuff, contained only 1.23 per cent of fat. This material is prepared by a patented process in which, according to a statement by the firm furnishing the meal for the test, all traces of injurious properties are removed. The material was costly as compared with other feeding stuffs, and the results of the test showed that it was not well suited for feeding dairy cows.

Influence of intervals between milkings on quality of milk, A. W. STOKES (*Dairy*, 12 (1900), No. 143, pp. 319, 320).—A herd of 21 cows was milked at 4 a. m. and 1 p. m., making the intervals between milkings, therefore, 9 and 15 hours respectively. Samples of the milk of each cow were taken at both milkings on August 4, 10, and 24, and September 11, and analyzed. Analytical data for 2 milkings at the beginning and end of the test are given. Sixteen of the cows gave milk on one or more occasions having less than 3 per cent of fat or less than 8.5 per cent of solids-not-fat. Of the 84 samples taken at the 1 o'clock milkings none contained less than 3 per cent of fat. Nine cows, however, gave milk containing less than 8.5 per cent of solids-not-fat. Of the 84 samples of morning's milk, 17 contained less than 3 per cent of fat and 19 less than 8.5 per cent of solids-not-fat. The milk drawn after the long interval was therefore poorer in quality than that drawn after the short interval. "It would seem as if the cows, as it were, took toll of it and reassimilated from it parts that they required for their own sustenance, if the milk were not drawn off at certain intervals."

Investigations of milk from mountain pastures (Satermelk), B. RAMSTAD (*Aarsber. Offent. Foranst. Landbr. Fremme*, 1899, pp. 349-361).—The milk produced by cows on mountain pastures has the reputation of being richer in fat and more palatable than the winter milk, due possibly to its deep yellow color. Goats' milk, on the other hand, retains its bluish-white color when produced in the mountains. Investigations by V. Dircks in the seventies showed, as the average of a large number of determinations, a daily yield of 4.3 liters of milk per cow on mountain pastures, with an average fat content of 3.9 per cent. In further study of this subject the author visited 7 mountain dairies (*såters*) in different parts of the interior of Norway, measured the milk of the cows in the various herds, and made separate analyses of the morning and evening milkings of each cow for 2 days. Samples of the mixed herd milk of the goats were also taken and analyzed.

The evening's milk was generally lower in fat than the morning's milk, the difference in some cases amounting to 2 per cent. The average percentage of fat in cows' milk was 3.807 per cent, agreeing closely with Dircks' figures, and also with the average of analyses of milk produced in the neighboring valleys during the same time of the year (July and August, 1898), which was 3.77 per cent.

The altitude of the pastures and their quality and location do not

seem to have an appreciable influence on the fat content of the milk. The same observation was made in the case of the milch goats.—F. W. WOLL.

The germ content of milk, O. APPEL (*Molk. Ztg.*, 14 (1900), No. 17, pp. 277, 278).—Experiments were made to determine the presence or absence of bacteria in the cow's udder. In one series of the experiments milking tubes were used and in another the milk for examination was drawn directly into flasks. Determinations were made of the number of bacteria present in samples of milk taken at the beginning, twice during the process, and near the end of milking. In the second series of experiments germ-free milk was obtained near the end of milking. The decrease in the germ content of the milk during milking was less marked when milking tubes were used. The introduction of the tube was thought to carry germs into the interior of the udder. Pure cultures of *Bacterium lactis aërogenes* and other bacteria were added to sterile milk and injected into the udder. A swelling of the udder and marked changes in the milk followed such inoculation. No bad effects were observed as a result of injecting sterile milk or water. The different experiments are considered as showing that bacteria are not normally present in the udder. The author also discusses the number and character of the germs found in milk and their destruction by heat.

Examination of butter color, F. H. WERENSKIOLD (*Aarsber. Offent. Foranst. Landbr. Fremme*, 1899, pp. 162, 163).—The author examined 9 samples of butter color, of which number 6 gave no reaction for aniline color and 3 were pure annatto color. The following method of determining the strength of color was used: A standard solution of 1 gm. potassium bichromate dissolved in a liter of distilled water was placed in a Hehner colorimeter; 0.5 cc. of the butter color was dissolved in 100 cc. of petroleum ether and compared with the standard solution. From 48 to 64 cc. of the aniline-free butter colors was required to give the same tint as the standard solution, while in case of the aniline colors from 31.3 to 50.3 cc. was required.—F. W. WOLL.

Experiments with calcium chlorid for rendering heated milk suitable for cheese making, KLEIN and A. KIRSTEN (*Milch Ztg.* 29 (1900), Nos. 12, pp. 177-179; 13, pp. 196-199; 14, pp. 210-213; 16, pp. 242-245; 17, pp. 258, 259).—A brief summary is given of an investigation previously noted (E. S. R., 10, p. 1092), and 5 series of experiments in continuation of that work are reported in detail.

The present investigation included in all 56 trials with skim milk and 2 with whole milk. Of this number 18 were control tests with unheated milk. In the remainder the milk was heated to 85° C. for 10 minutes, to 85-90° for 15 minutes, or to 100° for 2 minutes, and calcium chlorid equivalent to 25 gm. of calcium oxid per liter of milk was added. In different experiments after heating and cooling and

before adding the calcium chlorid and rennet, $2\frac{1}{2}$ per cent of the milk was replaced by skim milk which had been kept at 40° C. for 1 to 2 hours or by skim milk to which different pure cultures had been added; 5 per cent was replaced by fresh whole milk; or $\frac{1}{4}$ per cent was replaced by partly ripened cheese which was thoroughly powdered and mixed with the milk. In a large number of the experiments the curd was subsequently heated at 40 or 45° C. to hasten the separation of the whey and to increase the adhesiveness of the curd. The data for all of the experiments are given in tabular form and are discussed at some length.

The results in general agree with those obtained in the earlier experiments. By the use of calcium chlorid and pure cultures normal cheese of different kinds was made from skim milk and also from whole milk which had been heated at a high temperature. In 23 of the tests in which normal cheese was made from heated milk the average yield of ripe cheese was increased 32 per cent over that from unheated milk. The average increased yield of dry material in the cheese amounted to 12 per cent. This gain is considered more than sufficient to pay for the cost of heating and a clear profit where pasteurization is required. Heating at 100° increased the yield over heating at 85 – 90° , due to a more complete coagulation of the soluble casein. In none of the experiments was the subsequent heating at 45° sufficient to reduce the percentage of whey in the curd or ripe cheese to that in cheese made from unheated milk.

A sour milk cheese of normal quality was prepared from heated milk to which 10 per cent of sour milk was added without the use of calcium chlorid. This is noted as essentially the same result as that secured by Hamilton (E. S. R., 12, p. 288).

Evolution and development of the dairy cow, KATE M. BUSICK (*Amer. Cheese-maker*, 15 (1900), No. 177, pp. 6, 7).—A general discussion.

Studies on the milk production of individual cows, F. HÜBNER (*Molk. Ztg.*, 14 (1900), No. 26, pp. 437–440).—A monthly record of 40 cows for one year is given, with a summary of the principal data and notes on the management of the herd.

Feeding experiment with palm-nut residue, P. VIETH (*Milch Ztg.*, 29 (1900), No. 19, pp. 294, 295).—In an experiment with 6 cows, covering 4 periods of 10 days each, the residue from the manufacture of oil from palm nuts was compared with an equal quantity of a mixture of cotton-seed meal and bran (1:3) in rations otherwise alike. The results as regards both the total yield of milk and the yields of fat and solids were slightly in favor of the ration containing the palm-nut residue. The cost of the palm-nut residue was also 4 per cent cheaper than that of the contrasted feeding stuffs.

Value of molasses as food, P. HOPPE (*Ztschr. Ver. Deut. Zuckerind.*, 1900, No. 535, II, pp. 713–762; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 456, II, p. 681).—In experiments with cows, 5 kg. of molasses per day was fed without injury to digestion. As a rule, the milk yield was increased, although the percentage of fat was distinctly diminished.

Record of dairy herd, R. ROBERTSON (*Canada Expt. Farms Rpts. 1899*, pp. 250-252).—A record of 31 cows for one year, showing yield and fat content of milk, cost of feed, etc. The profit from individual cows ranged from \$2.68 to \$27.83.

How to distinguish between good and bad milk, E. H. FARRINGTON (*Amer. Cheesemaker*, 15 (1900), No. 177, p. 4).—A description of the Wisconsin curd test.

Human milk, E. F. LADD (*Sanitary Home*, 2 (1900), No. 8, pp. 181-183).—Analyses are given of 11 samples. The fat content varied from 1.5 to 7.32 per cent and the casein from 0.63 to 2.66 per cent.

Notes on the purification of milk, O. KRÖHNKE (*Milch Ztg.*, 25 (1900), No. 23, pp. 356, 357).—A discussion of different methods.

Contamination of dairy produce and its causes, G. S. THOMSON (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 3, pp. 257-263).—This is a general discussion of the subject. The appearance of cultures made from moldy cream and butter, dirt from hands of milker, sterilized and contaminated milk and cream, good and impure factory water, etc., is shown in plates. Different micro-organisms found in milk are also figured. Notes are given on colostrum milk and its detection.

Cream ripening by direct inoculation, A. ZOFFMANN (*Milch Ztg.*, 29 (1900), No. 17, pp. 259, 260).—The author notes the preparation of a pure culture for adding directly to cream, thereby avoiding the trouble required in preparing the usual starter. One hundred grams of the author's culture ripened about 250 liters of pasteurized cream in 16 to 20 hours. In 4 comparative tests, the yield of butter is reported as considerably increased and the quality noticeably improved by the use of the author's culture as compared with the use of a buttermilk starter.

Butter, A. M. PETER (*Kentucky Sta. Rpt. 1898*, pp. XIII-XV).—Tabulated analyses showing content of fat, water, salt, and curd are given of 140 samples of butter made at the station in churn tests of 7 Jersey cows.

Nevada butters, N. E. WILSON (*Nevada Sta. Bul.* 42, pp. 13, *dgm.* 1).—Brief notes are given on butter and its composition and analyses of 7 samples of creamery butter and 9 of dairy butter from different parts of the State are reported in tables and also diagrammatically. The results are compared with analyses of Connecticut dairy and creamery butter, California butter, and butter exhibited at the American Dairy Show at Chicago in 1882. The average composition of the samples of butter analyzed was as follows: Dairy butter—water 10.75, fat 84.74, casein 1.24, and ash 3.07 per cent; creamery butter—water 12.27, fat 83.47, casein 1.18, and ash 2.77 per cent.

Grading butter and its educational value, G. S. THOMSON (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 3, pp. 263-265).—Notes are given on the system of grading butter employed in South Australia.

Loss due to bad flavor, gas, and overripe milk, H. H. DEAN (*Amer. Cheesemaker*, 15 (1900), No. 177, p. 1).—Contains suggestions on cheese making with brief statements of results of experiments at the Ontario Agricultural College.

Influence of salt on the color of butter, A. V. BRANTH (*Milch. Ztg.*, 29 (1900), No. 17, p. 265).—Several experiments are briefly reported in which the discoloration of butter was considered due to chemical impurities in the salt.

Microbes in cheese making, H. W. CONN (*Pop. Sci. Mo.*, 58 (1900), No. 2, pp. 148-155).—A general discussion of the ripening of soft and hard cheese. Problems for investigation along this line are pointed out.

Cheese making, J. W. DECKER (*Columbus, Ohio: J. W. Decker, 1900*, pp. XIII+192, pls. 25, figs. 43).—This is intended primarily as a text-book and embraces a second revision of the author's work on Cheddar cheese making, and in addition a discussion of the manufacture of Swiss, brick, Limburger, Edam, and cottage cheese. References to original publications are given.

VETERINARY SCIENCE AND PRACTICE.

Tuberculin experiments in cattle, F. HUTYRA (*Ztschr. Tiermed.*, 4 (1900), No. 1, pp. 1-27).—The author believes that in the application of the tuberculin test it is quite sufficient to take the body temperature only once before inoculation with tuberculin. After inoculation it is not necessary to take the temperature until the ninth hour, and then every 3 hours rather than every 2 hours. All animals are to be considered as tuberculous which show a temperature reaction of 1.5° C. after injection with tuberculin; also all animals which show a temperature reaction of 1 to 1.4° C., accompanied with other clinical symptoms. On the other hand there is no good reason to condemn animals when the temperature reaction is not greater than 1.4° C. and is unaccompanied with other clinical symptoms, provided that a careful examination of the animals has not disclosed any pathological changes or clinical evidence of tuberculosis.

The author has brought together in tabular form the clinical records of a large number of animals upon which experiments were made.

Experiments in feeding tuberculous milk, meat, and various organs, V. GALTIER (*Jour. Méd. Vét. et Zootech.*, 5. ser., 4 (1900), pp. 1-5).—An emulsion prepared from 2 spleens and 2 lungs of tuberculous rabbits was mixed with a liter of cow's milk. This mixture was filtered and divided into 4 equal parts. One part was not heated, while the other 3 parts were subjected for 6 minutes to temperatures of 70, 80, and 90° C., respectively. Four guinea pigs which were inoculated with the unheated milk died of generalized tuberculosis. Of the 4 guinea pigs which were inoculated with milk heated to 70° , 3 showed tuberculous lesions, and were killed on the fifth day after inoculation. On the same day one of the 4 guinea pigs which had been inoculated with milk heated to 80° showed tuberculous lesions, while the 4 which had been inoculated with milk heated to 90° were all healthy.

Several other similar experiments were conducted by the author, the results of which may be stated as follows: Milk is not thoroughly sterilized by subjection for 6 minutes to temperatures of 70, 75, 80, or 85° C. Exposure to these temperatures for 6 minutes only attenuated to a slight extent the virulence of the tubercle bacillus, and tuberculosis is produced by inoculation of even small doses of milk so treated. Exposure to a temperature of 75° for 20 minutes is not sufficient to destroy all the tubercle bacilli.

Feeding experiments were conducted by the author upon young pigs with tuberculous material which had previously been sterilized in an autoclave at 110° C. As a result of these experiments the author concludes that the consumption of tuberculous organs which have previously been sterilized does not produce poisoning or tuberculosis even when taken in considerable quantities and repeatedly.

Poisoning from ground sesame cakes, DEYERLING (*Deut. Thier-ärztl. Wchnschr.*, 8 (1900), No. 9, pp. 73, 74).—The author makes a report upon the symptoms and circumstances of poisoning in the case of 111 cattle from eating ground sesame cake. The animals had previously been fed small quantities of this substance, together with other fodder materials. At 5 o'clock in the afternoon all these animals received $1\frac{1}{2}$ lbs. of ground sesame cake in the place of cotton-seed meal. The animals also received quantities of sugar-beet leaves and hay and straw. About 15 minutes after feeding one animal was observed to be bloated, and within a short time all the animals manifested the same symptoms. These symptoms included tympanites, coughing, and difficult breathing. The animals all recovered.

In order to make sure that the ground sesame cake was the cause of the trouble the author obtained permission to experiment further with this substance. A few of the animals were fed ground sesame cake in addition to the regular ration which all received. The same symptoms were developed as before.

African horse sickness, J. McFADYEAN (*Jour. Comp. Path. and Ther.*, 13 (1900), No. 1, pp. 1-20).—The author makes a report on 14 experiments for the study of the symptoms, etiology, and treatment of this disease. It was shown that the pathogenic organism readily passes through the pores of the Berkfeld or Chamberland F. filter, even when they are suspended in liquids containing a considerable amount of albumin. The experiments carried out by the author indicate that the disease may be transmitted to healthy horses by hypodermic inoculation with the fresh blood of a diseased horse, and also by introducing the material into the stomach. It would appear that under normal conditions the disease is most frequently transmitted by ingestion of the virus. So far as the author's observations go, it seems probable that the disease is not ordinarily acquired by inhalation.

The pathogenic organism of this disease has been called *œdemamyces* and has been believed to be a facultative parasite which is able to multiply rapidly outside of the animal body under favorable conditions of heat and moisture. It is believed by some that the organism is frequently taken into the body by eating dew-laden grass, but there is very little evidence to sustain this belief.

An elevation of temperature is the first symptom of infection by the African horse sickness. This rise of temperature takes place in from 4 to 7 days after inoculation and is not accompanied by rigor. In 5 cases of the disease produced experimentally, death occurred on the eighth day. The duration of the disease appeared to be the same in cases produced by inoculation and in those produced by ingestion of the virus. Detailed notes are given on the pathological anatomy in cases of death from this disease.

Immunization against rabies by means of normal nerve tissue, A. AUJESZKY (*Centbl. Bakt. u. Par., 1. Abt., 27 (1900), No. 1, pp. 5-10*).—Two dogs, weighing 6 and 5.5 kg., respectively, received a hypodermic injection daily from January 24 to February 11 of 10 cc. of an emulsion which had been prepared from the spinal cord of healthy cattle, in normal salt solution. On February 15 the dogs were inoculated in the ear with rabies virus. Injections were continued until February 25, so that each dog during the course of 34 days received 30 gm. of spinal cord. The control rabbit died on the thirty-fifth day, while the dogs remained healthy.

Three dogs, weighing 8, 8.7, and 6.5 kg., respectively, received injections of normal nerve tissue as in the previous experiment. Ten days after the beginning of these injections they were inoculated in the ear with rabies virus. The dogs showed symptoms of rabies sooner than the control animals.

Three other dogs, weighing 6, 8, and 5 kg., respectively, received injections of nerve substance as in the other experiments. When inoculated with laboratory rabies virus, the dogs remained well, but the control animal was also unaffected. When bitten by a rabid dog, all showed symptoms of the disease within a short time.

From these investigations it is concluded that hypodermic injections with emulsions of normal nerve tissue are not sufficient to protect animals against the more virulent rabies virus. In the first-mentioned experiments, where this method seemed to be successful, the virulence of the rabies virus was not determined, and it is possible that it was not strong enough to produce rabies.

The prophylaxis of malarial fever by means of protection against mosquitoes, E. DI MATTEI (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 6-7, pp. 189-195*).—An experiment was conducted by the author on 4 men in Catania for the purpose of determining whether malarial fever could be contracted without the agency of mosquitoes. The 4 men who submitted to the experiment slept in an exceedingly malarial district for 32 nights with doors and windows open, but covered with close netting which prevented the entrance of all mosquitoes, and no case of malaria developed in any of the 4 men.

The influence of tetanus toxin on the central nervous system, M. JOURKOWSKY (*Ann. Inst. Pasteur, 14 (1900), No. 7, pp. 464-478, pl. 1*).—In cases of poisoning from tetanus toxin, modifications in the nerve cells of the medulla and to a certain extent in those of the cerebrum are to be noted. The modifications of the cell nuclei are variable and can not be considered characteristic of this disease. Another pathological condition is more uniformly observed and consists in the accumulation of mononuclear migratory cells around the nerve cells. These migratory cells penetrate the protoplasm of the nerve cells, especially in the anterior group of cells of the anterior cornua. This phenomenon is to be considered as a phagocytosis.

Text-book of special pathology and therapy of domesticated animals, F. FRIEDBERGER and E. FRÖHNER (*Lehrbuch der speciellen Pathologie und Therapie der Hausthiere. Stuttgart: Ferdinand Enke, 1900, 5. ed., vol. 1, pp. 867*).—This volume contains an elaborate discussion of the various diseases of the digestive organs, liver, diaphragm, spleen, urinary and genital organs, heart and larger blood vessels, skin, locomotor organs, and nervous system.

Analyses of urine for the detection of antipyretics, A. PETERMANN (*Bul. Sta.*

Agron. Gembloux, 1900, No. 68, pp. 9-11).—The veterinary service having heard rumors of the fraudulent use of antipyretics for the purpose of preventing the reaction of cattle to the tuberculin test undertook the analysis of the urine of tested animals for the purpose of determining whether such substances had been used fraudulently or not. Salicylate of soda and salol are the substances which have thus far been detected and they were present in the urine in the form of salicylic acid. For the purpose of coming to more definite conclusions in this matter further investigations will be made on antipyrin and coloring matters in the urine.

Changes in the kidneys during pulmonary tuberculosis in relation to the excretion of the tubercle toxin and the tubercle bacillus, G. D'ARRIGO (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 8-9, pp. 225-228*).—During pulmonary tuberculosis it was found that alterations were produced in the blood vessels, interstitial connective tissues, glomeruli, and epithelium of the kidneys. At first the tubercle toxin is present only in small quantities and is not accompanied by the tubercle bacillus, but after pathological changes have been produced in the kidneys by the action of the toxin the tubercle bacillus soon invades the kidneys and may in many instances be the primary cause of death.

Transmission of tuberculosis through the meat and milk supply, J. J. REPP (*Reprint from Philadelphia Med. Jour., 1900, Aug. 11, pp. 22*).—The author presents a critical account of the literature relating to the transmission of tuberculosis from animal to animal and from animal to man by means of meat, artificial inoculation, milk supply, and other natural methods. The author believes that the results thus far obtained indicate that tuberculosis may be transmitted to the lower animals by the ingestion of tuberculous meat or milk and that the meat and milk of certain tuberculous animals contain living virulent bacilli.

Acceleration in the culture of the tubercle bacillus, W. HESSE (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 8-9, pp. 255-257*).—A controversial article regarding the method already proposed by the author for the speedy cultural diagnosis of the tubercle bacillus.

Texas fever in the South, R. W. CLARK (*Farm Students' Rev., 5 (1900), No. 10, p. 149*).—A brief discussion of the nature of Texas fever and of the great economic importance of immunization methods against this disease.

The prevention of Texas cattle fever and the amended laws controlling contagious and infectious diseases, C. McCULLOCH (*Virginia Sta. Bul. 104, pp. 165-180, fig. 1*).—This bulletin contains a brief review of the experimental work done on the cattle tick and Texas fever by the Bureau of Animal Industry of this Department and the agricultural experiment stations in Texas, Missouri, and Louisiana. Appended to this review is a copy of the act of the general assembly of Virginia providing for the protection of domestic animals and for the establishment of quarantine laws, rules, and regulations.

Blackleg: Its nature, cause, and prevention, V. A. NØRGAARD (*U. S. Dept. Agr., Bureau of Animal Industry Circ. 31, pp. 22*).—This circular is an abstract of the author's article on the same subject in the Fifteenth Annual Report of the Bureau (*E. S. R., 10, pp. 991-993*).

Blackleg vaccine, E. P. NILES (*Virginia Sta. Bul. 103, pp. 153-163, figs. 2*).—A revision of Bulletin 90 of the station (*E. S. R., 11, p. 494*).

The Cyprus sphalangi and its connection with anthrax, G. A. WILLIAMSON (*British Med. Jour., 1900, No. 2070, pp. 558-561, figs. 7*).—The insects called sphalangi in Cyprus belong to the genus *Mutilla*. A number of cases of anthrax in man are reported by the author, with accounts of the circumstances surrounding the cases. The author believes that the anthrax bacillus is frequently carried upon the sphalangi insects, and that human beings may become inoculated with the disease either from the bites of the infected insects or from their contact with wounds.

Variations in the power of anthrax bacillus in liquefying gelatin, T. MATZUSCHITKA (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 10-11, pp. 303, 304*).—Cul-

tures of anthrax bacillus which had been maintained for $1\frac{1}{2}$ years upon a 10 per cent gelatin medium at the living temperature, and which had been transferred at intervals of 2 or 3 months during this time, lost the power of liquefying gelatin to such an extent that this process took place only to a slight degree after 50 days. The anthrax cultures which had lost this characteristic of liquefying gelatin remained as virulent as other anthrax cultures. The power of liquefying gelatin gradually returned after 4 to 6 transfers upon agar medium at a temperature of 37° C.

The practical working of regulations for combating foot and mouth disease (*Arch. Deut. Landw. Raths*, 24 (1900), pp. 243-274).—After a discussion of the problem at the twenty-eighth meeting of the German Agricultural Commission, it was resolved that the present regulations regarding this disease are not well adapted to prevent the spread of the disease, and that at the same time they work unnecessary hardships upon certain stock owners and shippers. It was further resolved that a commission be selected to report upon more suitable regulations regarding this matter.

Contribution to the study of antileucocyte serums—their action upon the coagulation of blood, C. DELEZENNE (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 14, pp. 938-940).—The author's experiments were conducted on dogs and rabbits. It was found that the antileucocyte serum when mixed with the blood of the dog in a glass vessel hastened the process of coagulation. When injected directly into the circulation the serum had the opposite effect.

Antirabies vaccinations at the Pasteur Institute in 1899, E. VIALA (*Ann. Inst. Pasteur*, 14 (1900), No. 7, pp. 487-491).—Brief notes on the history of the 1,614 cases treated, including observations on the rabid animals.
